The diagrams of two accurately measured front boundaries are shown in Fig. 1. Curve *a* is the eluted front boundary of a 1N-[CoCl₂] band after passing 3g of acid permutite. The isotherm is approximately of the Langmuir type with a value of $b \approx 3-4$ (thus $bc^0 = 3-4$). A comparison with the corresponding calculated curves in Fig. 3 shows a good agreement. Curve *b* shows an inter-boundary between a mixture of ⁵⁹Co and ⁶⁰Co against a front-band of pure ⁵⁹Co, where the rise in the concentration of ⁶⁰Co has been measured. As the exchange isotherm between the two isotopes is strictly linear, there is no self-sharpening to be expected, and the experiment shows, in agreement with the theory, a symmetrical S-form for this front boundary.

The elution curve of the boundary of the two isotopes was measured by means of the β activity of ^{60}Co ($\tau = 5.5$ years) in single drops of eluate which were dried on filter-paper.

(d) *Effect of Non-equilibrium on Separation of Two Solutes.*—A typical example of the importance of such considerations is shown in the separation of copper and nickel on commercial alumina by Jacob and Tompkins (*loc. cit.*, p. 398, Fig. 3), using a linear flow velocity of 0.07 cm./sec. Even after the band has travelled several times the distance which they expect to be required for complete separation, the mixed part of the band still contains about 70% of the nickel and about 30% of the total copper.

We obtained very similar results with copper and manganese (the latter being used instead of nickel owing to its easy volumetric determination). Using a flow velocity of 0.027 cm./sec. and 0.25N-sulphuric acid for elution on 2.2 g. of commercial alumina, we obtained the elution curve of Fig. 4a, which shows the retention of a mixed band with 47% of the manganese and about 25% of the copper. (Figs. 4a and b were obtained by analysing single drops of eluate.)

Elution curves of mixture of CuSO_4 and MnSO_4 chromatographed on 2.2 g. of Al_2O_3 . Development with 0.25N- H_2SO_4 .

Abscissa : volume of eluate after appearance of solute in eluate.

Ordinate : concentration of solutes in eluate (milliequiv./c.c.).

(a) Diameter of $\text{Al}_2\text{O}_3 = 0.08$ mm.; flow velocity = 0.027 cm./sec.

(b) Diameter of $\text{Al}_2\text{O}_3 = 0.01$ mm.; flow velocity = 0.0014 cm./sec.

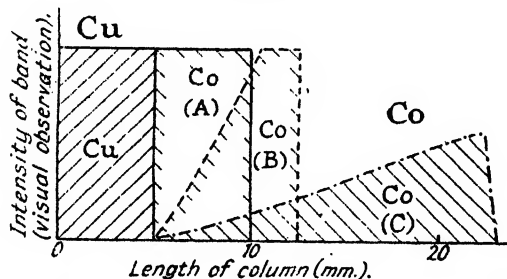

By reducing the grain size from 0.08 to 0.01 mm. diameter and the flow velocity to 0.0014 cm./sec., and otherwise using identical conditions, the effect of the diffusion and non-equilibrium phenomena was much reduced (see Fig. 4b). The mixed part of the band now contained only 20% of the manganese and 14% of the eluted copper, and in some experiments still less. (Actually, separation appeared to be much more complete in the column, and the small amount of mixing observed in the eluate seemed to be due to the mixing of 2 or 3 drops at the bottom of the tube.) Also, in other respects, the two experiments show marked differences. In the second experiment (Fig. 4b) all the front boundaries of the Mn^{++} , Cu^{++} , and H^+ are fairly steep, and the flat levels of the manganese and copper bands show clearly that these bands are not being "developed" by a diffuse rear boundary, a feature which is lost completely through non-equilibrium phenomena in Fig. 4a, and in the copper elution curves of Jacob and Tompkins (*loc. cit.*, p. 402, Fig. 2).

Although, under ordinary working conditions (commercial grain size and usual flow rate), some separation is still shown in cases where the differences in adsorption affinity and the self-sharpening tendencies of the inter-front are comparatively large, as is the case for Cu-Ni and Cu-Mn, it becomes impossible to separate solutes of very similar adsorption affinity, which consequently have fairly linear exchange isotherms, and whose inter-front is practically non-self-sharpening.

Such solutes as, *e.g.*, the group Ni, Co, Cd, Fe^{II}, are usually considered as non-separable (see Schwab and Jockers, *Z. angew. Chem.*, 1937, 50, 646), but their inseparability is entirely due to the disturbing influence of diffusion and non-equilibrium phenomena which almost completely undo any chromatographic separation. No difficulty is experienced in effecting an almost complete separation—with adjoining bands, of course—between any two of these solutes if a smaller grain size and a lower rate of flow is employed. To give an example: 0.15 c.c. of 0.5N-NiSO₄ + 0.5N-CoSO₄ were developed with 0.25N-H₂SO₄. The original band, in a column of alumina of 8 mm. diameter, had a length of 4.5 mm. The band at first broadened on development with the more dilute acid and, by the time the just visible rear band of nickel had travelled 6 mm., separation was complete, the nickel occupying a position between 6 and 12 mm., and the cobalt that from 12 to 18 mm. Treatment with dimethylglyoxime and ammonia showed that, if there were any overlap between the nickel and the cobalt zone, it must have been less than 1 mm. A quantity of 0.3 g. of alumina thus proved to be sufficient to separate almost quantitatively 0.15 milliequiv. of the "inseparable" cobalt-nickel sulphate mixture.

It should also be mentioned that, as a result of using finer grain, the quality of packing was much improved. The boundaries obtained were absolutely straight. Fringes—only observable under the microscope—did not exceed 3–4 grain diameters, *i.e.*, 0.04 mm. on any of the boundaries of Fig. 4b.

FIG. 5.

Chromatogram of mixture of CuSO₄ and CoSO₄ on Al₂O₃. Development with MnSO₄ solution. Cu band remains at the top of the column. Three stages in the "development" of the Co band are shown.

(e) *Separation into Isolated Bands.*—As the slow separation of metal ions on fine-grain alumina proved so successful, an attempt was made to obtain a complete separation into isolated bands. With acid as developing agent, this is of course not possible, as hydrogen ions are the most strongly adsorbed ions and, consequently, the bands cannot be expected to separate (see Glueckauf, Part I, *Proc. Roy. Soc.*, 1946, A, 186, 50, case 4). If a complete separation, *e.g.*, of copper and cobalt bands is required, development must be attempted with a less adsorbed solute, such as Mg⁺⁺ or Mn⁺⁺ solutions.

Fig. 5 shows the approximate distributions of the separated bands observed during a chromatographic separation of 0.15 c.c. of 0.5N-CuSO₄ + 0.5N-CoSO₄, developed with 1, 1.5, and 4.5 c.c. of 0.5N-MnSO₄ solution. Already after 1 c.c. of developing solvent had been added, the separation of copper and cobalt seemed almost complete, resulting in adjoining bands of about equal width. Further development hardly altered the position of the copper band. The front of the cobalt band continued to move down the column, but the tail end, though greatly decreasing in concentration, never moved away from the front of the copper band, a typical sign that cobalt ions follow a Freundlich isotherm even in the presence of 0.5N-Mn⁺⁺. (During the development it looked as if the bands were actually completely apart, but subsequent treatment with ammonium sulphide showed that the cobalt band reached right back to the copper front.)

Thus, if separation into two entirely separated bands were required, it would in this case be necessary either to develop with a solute of intermediate adsorption affinity (*e.g.*, zinc), or to add such a solute to the mixture and develop with acid.

Somewhat similar is the separation of nickel and cobalt with 0.5N-MnSO₄ solution as developing agent. Here both bands attained a triangular shape of approximately equal length, the nickel band beginning at the top of the column, and the cobalt band at the fairly sharp front of the nickel band. (The cobalt band was here not actually a triangle, but began

with a definite concentration, as must be expected for Freundlich isotherms. This is shown in detail in Figs. 4, 5, and 6 of Part V.)

Our thanks are due to Dr. H. London, University of Birmingham, who first drew our attention to the great importance of non-equilibrium phenomena for the separation of solutes of very similar adsorption affinity.

242. Theory of Chromatography. Part V. Separation of Two Solutes Following a Freundlich Isotherm.

By E. GLUECKAUF.

An attempt is made to predict the behaviour during chromatographic separation of solutes following individually a Freundlich isotherm $ac = q^n$. A method is shown for the graphical solution of the fundamental chromatographic equation $dq_1/dc_1 = dq_2/dc_2$, which makes it possible to calculate the distribution of solutes in binary chromatograms for any type of isotherm. It is shown that in the case of Freundlich isotherms two essentially different types of chromatogram must be expected (see Figs. 4 and 6). In order to obtain complete separability into two adjoining bands the condition must be fulfilled that the molar phase ratio at the point of separation of the bands

$$\left[\frac{q_2}{c_2} \cdot \frac{c_1}{q_1} \right]_0 > n_2$$

If the leading solute has the lower value of n , i.e., if $n_1 < n_2$, this can always be achieved by working at low enough concentrations. If this condition is not fulfilled, solute 2 cannot be obtained pure, but can only be enriched. Pure solute 1 can always be obtained, though in the latter case not quantitatively. Chromatographic separation is the easier the smaller the ratio n_1/n_2 of the Freundlich exponent.

(a) *An Isotherm for Multiple Solutes.*—The case of the Langmuir isotherm has been dealt with in considerable detail in an earlier publication. In deducing what happens in the case of two substances each following a Freundlich isotherm, the difficulty arises that no isotherm of the Freundlich type has so far been suggested for multiple solutes. Nevertheless, we may assume that, just as the simple Freundlich isotherm $q = (ac)^n$ can be replaced by a sum of Langmuir equations

$$q = \sum_1^n \frac{a_i c_i}{1 + b_i c_i} \quad \dots \quad (1)$$

as has been suggested by Hinshelwood ("Kinetics of Chemical Change in Gaseous Systems", 2nd edition, p. 195), the multiple Freundlich isotherm, if it existed, might be synthesised as

$$q_1 = \sum_1^n \frac{a_{1i} c_{1i}}{1 + b_{1i} c_{1i} + b_{2i} c_{2i}} \quad \dots \quad (2)$$

An isotherm of this type, which still has a finite slope (dq/dc) at $c_1 = 0$ would show little difference in principle from the chromatographic behaviour of a "pure" Langmuir isotherm, and such differences would be confined mainly to a smaller rate of separation at the rear end (see, e.g., Part III, Fig. 2).

Another possibility is to write the Freundlich equation in the form

$$ac = q(q)^{n-1} \quad \dots \quad (3)$$

and compare it with the Langmuir equation in the form

$$ac = q(1 - \beta q)^{-1} \quad \dots \quad (4)$$

where $\beta = b/a$ represents the amount of adsorbent occupied at saturation by 1 mol. of adsorbate. If the mechanism of adsorption is similar, we may reasonably assume that in both cases the concentration of the solute is in the first instance proportional to the concentration in the adsorbed state (q), modified by a factor which is dependent on the amount of free adsorbing space still available, which is a function of the amount absorbed. In the case of the multiple Langmuir isotherm this modifying function is

$$\left[1 - \beta_1 \left(q_1 + \frac{\beta_2}{\beta_1} q_2 \right) \right]^{-1}$$

We may assume that a similar additivity would exist for the occupied surface areas in the case of the modifying function of a multiple Freundlich isotherm, which would then have the form, analogous to eqn. (3) :

$$\left. \begin{aligned} a_1 c_1 &= q_1 \left(q_1 + \frac{\beta_2}{\beta_1} q_2 \right)^{n_1-1} \\ a_2 c_2 &= q_2 \left(\frac{\beta_1}{\beta_2} q_1 + q_2 \right)^{n_2-1} \end{aligned} \right\} \dots \dots \dots (5a, b)$$

Equation (5a, b), which, like the Freundlich equation, can only be considered as empirical, should make it possible to predict the conditions of mixed adsorption when the single-solute isotherms are known, at least if the surface requirements β can be considered identical.

Actually it is possible to make physical assumptions which link the Freundlich isotherm with the theoretically deduced Langmuir equation (though it cannot be discussed here how far these assumptions are justified). We may assume that every part of the surface can become an actively adsorbing spot, if raised temporarily to a higher energy level P which in this case corresponds to a state of unsaturation. The higher this degree of unsaturation, the larger must be the activation energy P , but the greater will be the amount of desorption energy Q which an adsorbed solute requires for its removal from this activated spot. The simplest assumption would be that P and Q form, at a given temperature, a definite ratio $P/Q = m$, where $m < 1$, so that activation + adsorption results in an exothermic process.

A Maxwell-Boltzmann distribution being assumed for the P levels, the proportion of active surface ΔS_Q adsorbing with an adsorption energy between Q and $Q + \Delta Q$ is

$$\frac{\Delta S_Q}{\Delta Q} = \frac{m}{RT} \cdot e^{-mQ/RT} \dots \dots \dots (a1)$$

There is no reason why in normal cases a group of active spots of uniform properties should not adsorb according to the Langmuir isotherm :

$$\Delta q_Q = \frac{\Delta S_Q}{\beta} \cdot \frac{Kc e^{Q/RT}}{(1 + Kc e^{Q/RT})} = \frac{\Delta S_Q}{\beta} \cdot \frac{b_Q c}{1 + b_Q c} \dots \dots \dots (a2)$$

Replacement of ΔS_Q in (a2) by means of (a1) and elimination of Q by b_Q leads to the equation

$$\Delta q_Q = \frac{m K^m c}{\beta \cdot b_Q^m (1 + b_Q c)} \cdot \Delta b_Q \dots \dots \dots (a3)$$

and integrating over all values of Q , i.e., for all adsorption factors b from 0 to ∞ , we have

$$q = \frac{m K^m c}{\beta} \int_0^\infty \frac{db}{b^m (1 + bc)} \dots \dots \dots (a4)$$

which for $0 < m < 1$ results in

$$q = \frac{m \pi K^m}{\beta \sin m\pi} \cdot c^m = A c^m \dots \dots \dots (a5)$$

This is the well-known form of the Freundlich isotherm.

The same considerations can be applied to the case of two solutes. This leads eventually to

$$q_1 = \frac{m_1 K_1^{m_1} c_1}{\beta_1} \int_0^\infty \frac{db_1}{b_1^{m_1} \left[1 + b_1 c_1 + \left(\frac{b_1}{K_1} \right)^{m_2/m_1} K_2 c_2 \right]} \dots \dots \dots (a6)$$

which integral appears to be soluble only for the case $m_1 = m_2$. In this case, integration leads to equations for q_1 and q_2 which are almost identical with the equations 5c, d. This gives some theoretical support for the multiple adsorption isotherms 5a, b, though only in the case $n_1 = n_2$.

Unfortunately, very few experimental data on mixed adsorption are available to test the usefulness of equation (5a, b), one of the best examples being the adsorption of oxalic (1) and succinic (2) acids on charcoal (probably by Masius; see Freundlich, "Colloid and Capillary Chemistry," Methuen, Fig. 39, p. 200). The Freundlich isotherms of the single solutes obtained from the experimental data are $40c_1 = (q_1)^{1.1}$ and $216c_2 = (q_2)^{2.6}$, where c is measured in mol./l. and q in millimol. per g. of charcoal, from which would follow in accordance with eqn. (5a, b), the multiple isotherms

$$40c_1 = q_1 \left(q_1 + \frac{\beta_2}{\beta_1} q_2 \right)^{1.1} \dots \dots \dots (5a')$$

$$216c_2 = q_2 \left(\frac{\beta_1}{\beta_2} q_1 + q_2 \right)^{2.6} \dots \dots \dots (5b')$$

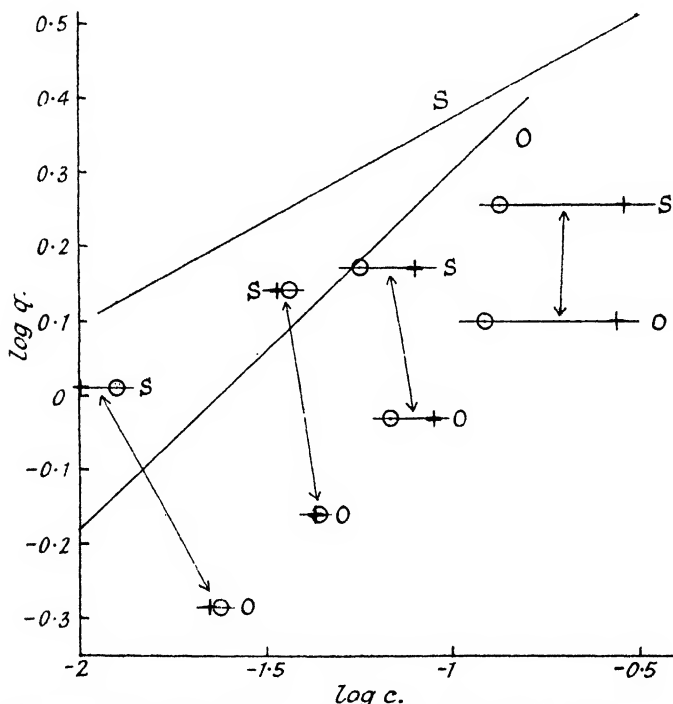

Fig. 1 shows the straight lines of the single-solute isotherms of succinic acid (S) and oxalic acid (O), as well as a number of points giving the measured adsorption equilibria for approximately

equimolar solutions of the mixed solutes, the points of coexisting concentrations being tied by arrows. From the values of q_1 and q_2 of these points the "theoretical" values of c_1 and c_2 have been calculated by means of eqns. (5a') and (5b'), and the resulting points are shown in Fig. 1 as circles: β_2/β_1 has been chosen as 1.2 which slightly improves the agreement as compared with the assumption of equal surface requirements. Though the deviations of the calculated values of c_1 and c_2 from the observed values are not negligible, it is apparent that the equations (5a') and (5b'), the constants of which are taken from the single-solute isotherm, express the conditions of mixed adsorption with reasonable approximation.

Much better is the agreement with the experimental values if we consider the effect of the total adsorbate on the molar phase ratio ξ obtained from eqns. (5a) and (5b) :

$$\xi = \frac{c_1/q_1}{c_2/q_2} = \frac{a_2}{a_1} \left(\frac{\beta_2}{\beta_1} \right)^{n_1-1} \cdot \left(\frac{\beta_1}{\beta_2} q_1 + q_2 \right)^{n_1-n_2} \quad \dots \quad (6)$$

FIG. 1.

Adsorption of succinic and oxalic acid on charcoal. The lines represent the adsorption of the single solutes; the points show the data of mixed adsorption of the two acids, coexisting concentrations being tied by arrows. (+) observed data, (○) calculated from single solute isotherms by eqn. (5a', b').

(see Fig. 2). Here the points correspond to the experimental values of c_1 , c_2 , q_1 , q_2 , and the line is obtained from eqn. (6) with $\beta_2/\beta_1 = 1.2$, and all the other constants are taken from the single-solute isotherms. ξ is the separation factor and its importance for the chromatographic separation is similar to that of the molar phase ratio of the gaseous and the liquid phase for fractional distillation. The agreement is so much better here because any effects of mutual attraction or repulsion between the different adsorbed solutes, e.g., due to the heat of mixing in the surface, which are not considered in eqn. (5a, b), are greatly reduced in ξ . This, too, has its parallel in the vapour pressures of binary liquids, where the agreement between theory and experiment is always better for the molar phase ratio than for the concentration-pressure curves.

Very similar conditions exist in the case of the binary adsorption of acetone (i) and acetic acid (ii) on charcoal. The single-solute isotherms are here (see experiments by Michaelis and Rona, *Biochem. Z.*, 1909, 15, 204—207)

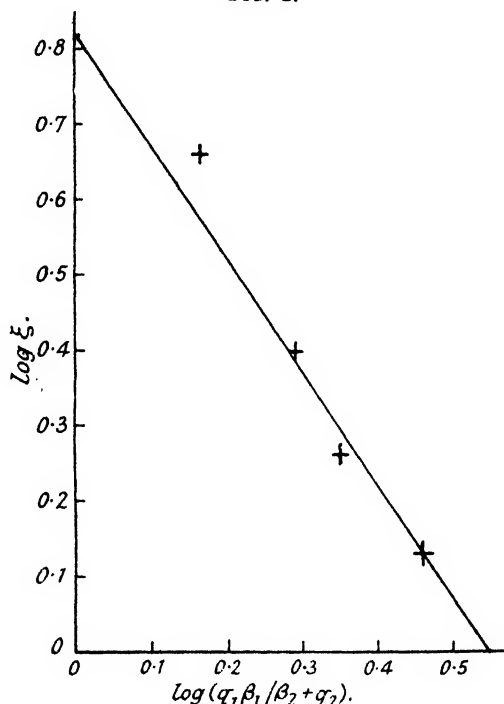

$$25c_1 = q_1^{2.0} \text{ and } 41.5c_2 = q_2^{3.0}$$

so that one might expect the multiple isotherms

$$25c_1 = q_1(q_1 + \epsilon q_2) \text{ and } 41.5c_2 = q_2 \left(\frac{q_1}{\epsilon} + q_2 \right)^2$$

At high concentrations of acetone, deviations due to the heat of mixing in the surface are again very marked, but at lower concentrations of acetone agreement is quite good (see Table I, where the concentrations in the solvent have been calculated for given quantities of adsorbate, using a value of $\epsilon = 0.65$), and Table II, where the amount of acetic acid required to produce a given distribution of

solute 1 between 50 c.c. of water and 1 g. of charcoal has been calculated from the adsorption data of solute 1.

These considerations should make it clear that substances separately obeying a Freundlich isotherm do not necessarily follow the binary isotherm (5a, b), but that this equation represents

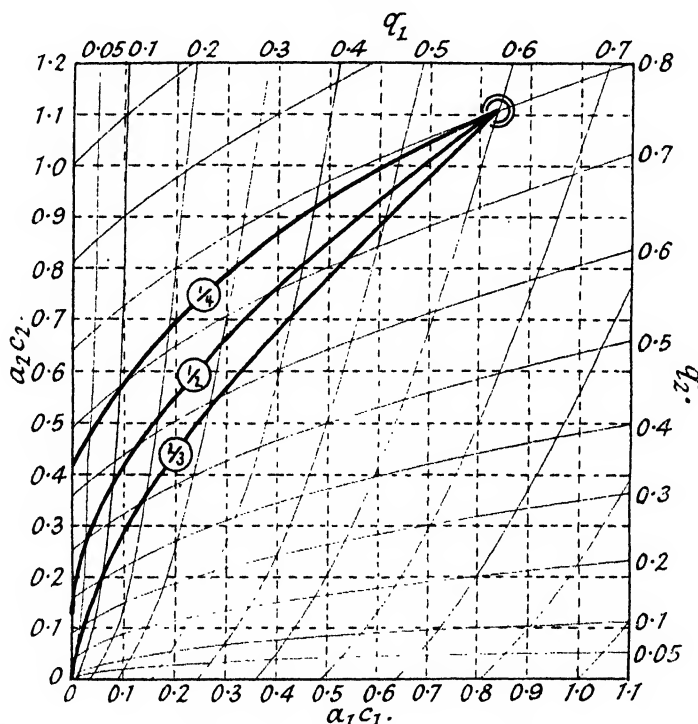

a function which contains many, though not necessarily all, the essential features, which may be expected from a multiple adsorption isotherm of such solutes. In particular, it contains the typical feature of the Freundlich isotherm of infinite slope at zero concentration.

For $n_1 = n_2$, $\beta_1 = \beta_2$. Eqn. (5a, b) can also be written in the form

$$\left. \begin{aligned} q_1 &= \frac{a_1 c_1}{(a_1 c_1 + a_2 c_2)^{1-1/n}} \\ q_2 &= \frac{a_2 c_2}{(a_1 c_1 + a_2 c_2)^{1-1/n}} \end{aligned} \right\} \quad \dots \dots \dots (5c, d)$$

which shows at the same time the formal resemblance to and also the essential difference from the multiple Langmuir isotherms.

FIG. 3.

Contour lines of the q_1 - c_1 - c_2 and of the q_2 - c_1 - c_2 surfaces, as required for obtaining the curve of coexistent values of c_1 and c_2 in the mixed part of the chromatogram for a given case of initial concentrations c_1^0 , c_2^0 (○). The three lines refer to three different values of a_1/a_2 ($= \frac{1}{4}$, $\frac{1}{2}$, and $\frac{3}{4}$).

(b) *Chromatographic Separation in the Case $n_1 = n_2$.*—In order to apply chromatographic equations to either eqn. (2) or (5), it is necessary to solve the fundamental differential equations governing the chromatographic process $dq_1/dc_1 = dq_2/dc_2$. As has been pointed out in Part I (*Proc. Roy. Soc., 1946, A, 186, 54*), a general solution is so far only possible in the case of the "pure" Langmuir isotherm. We can, however, solve this equation by graphical evaluation and thus obtain the relationships between coexistent values in the chromatogram of c_1 and c_2 or q_1 and q_2 in any numerical case.

For this purpose lines of equal q_1 and of equal q_2 are plotted on a system with the co-ordinates $a_1 c_1$ and $a_2 c_2$ (or c_1 and c_2) (see Fig. 3). These represent the contour lines of the three-dimensional q_1 - $a_1 c_1$ - $a_2 c_2$ and q_2 - $a_1 c_1$ - $a_2 c_2$ diagrams. We may then start with a point [representing the conditions of the original solution (c_1^0 , c_2^0) to be chromatographed] and, by a method of trial and error, find a neighbouring point which obeys the condition $\Delta q_1/\Delta c_1 = \Delta q_2/\Delta c_2$. Thence we proceed from point to point until one of the concentrations becomes zero. The resulting curve (thickly marked in Fig. 3) then represents the relationships between coexistent values in the mixed chromatogram of q_1 and q_2 , c_1 and c_2 .

In order to make a wider use of this diagram the evaluation has been made for three different values of a_1/a_2 ($= \frac{1}{2}, \frac{1}{3}, \frac{1}{4}$) which thus represent three different isotherms of the same type. The contour lines of Fig. 3 have been calculated for eqn. (5a, b) with $n_1 = n_2 = 2$ and $\beta_1/\beta_2 = 1$. In this case the position of the "coexistence line" depends on the ratio a_1/a_2 only, so no individual values need be assigned to these constants.

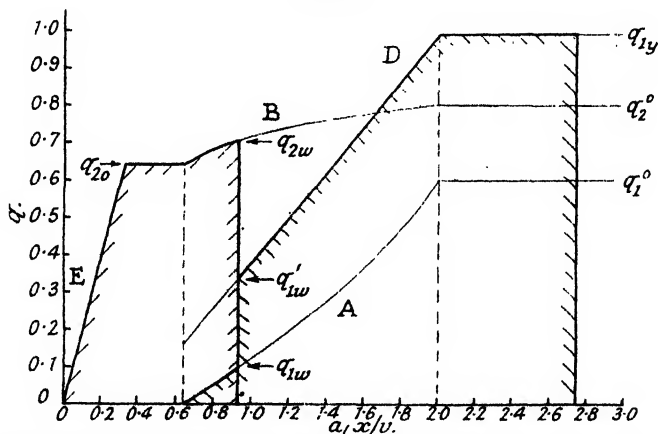

The starting concentrations of the adsorbate q_1^0 and q_2^0 have been chosen at random ($q_1^0 = 0.6$, $q_2^0 = 0.8$) and consequently $c_1^0 = 0.84/a_1$, $c_2^0 = 0.12/a_2$.

Each case of a_1/a_2 results in a function of coexistent values of c_1 and c_2 (and of q_1 and q_2 , respectively) and these functions differ greatly in their characteristics. It can be shown that different starting points c_1^0 , c_2^0 , q_1^0 , q_2^0 do not affect these characteristics, but that these depend on the ratio a_1/a_2 only. We always get types of function for coexistent values which can be represented with good approximation by the empirical equations (6a), (6b) and (6c), the value of the constants depending on the starting point.

a_1/a_2	Equations for coexistent values of q_1, q_2	Constants for $q_1^0 = 0.6$, $q_2^0 = 0.8$		
		k_1	k_2	k_3
$\frac{1}{2}$	$q_2 = k_1 + k_2 q_1 + k_3 q_1^2$	0.64	0.5	0.5 (6a)
$\frac{1}{3}$	$q_2 = k_1 + k_2 \sqrt{q_1}$	0.37	0.55	— (6b)
$\frac{1}{4}$	$q_2 = k_1^2 \sqrt{q_1} + k_2 q_1$	0.77	0.25	— (6c)

These relationships for coexistent values of q_1 and q_2 make it possible to substitute q_2 in the mixed isotherm (5a, b). This leads to the "pseudo-single-solute" isotherm $q_1 = F(c_1)$ required for the construction of the binary chromatograms according to the general equations given in Part III.

FIG. 4.

Boundary lines of chromatograms calculated for mixed isotherm with the constants $n_1 = n_2 = 2$ and mixed $a_1/a_2 = \frac{1}{2}$. Note similarity with the case of the Langmuir isotherm. Complete separation is attainable.

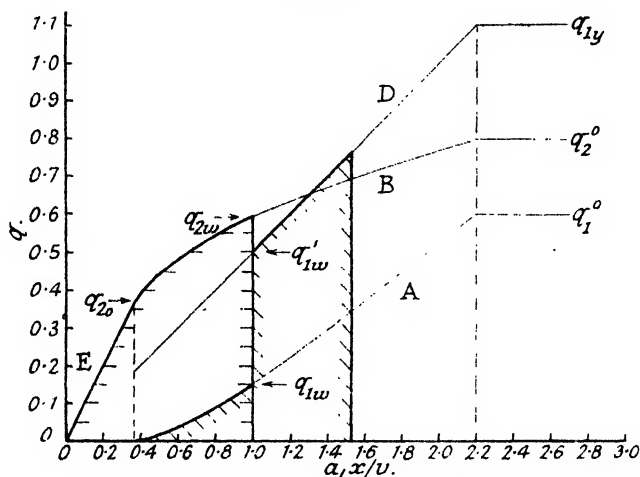

Figs. 4, 5, and 6 show the calculated loci of the chromatographic boundaries for the three cases considered ($a_1/a_2 = \frac{1}{2}, \frac{1}{3}, \frac{1}{4}$). Curves A and B represent the loci of the rear boundary of the mixed band for solute I and II respectively; curve D shows the rear slope of the pure frontal band of solute I, and curve E gives the diffuse rear boundary of the pure rear band of solute II. All the curves show the values of q_1 or q_2 plotted against the parameter a_1x/v as abscissa.

From these curves the actual form of the chromatograms can be obtained by fixing numerical values for the quantities of solutes (m_1, m_2) and for the volume v of solvent used. This defines the position x of the front boundaries of the mixed band and of the pure band of solute I. To make things clearer, these boundaries (for given cases of m and v) have been cross hatched; with these boundaries the abscissa represents the length of column (x) in an arbitrary unit.

We then see from Fig. 4 that, for solutes with values of $a_1/a_2 < \frac{1}{2}$, the general arrangement of the binary chromatogram shows little difference from that arising from a Langmuir isotherm (see Part I or Part III, Figs. 1a-e, Fig. 1A, B). The principal differences are that (a) the rear band does not separate from the top of the column, a known feature for Freundlich isotherms (see Weiss, *loc. cit.*, Fig. 4), and consequently is only very incompletely eluted, and (b) the

frontal band of solute 1 never completely separates from the rear band of solute 2, even after the mixed band has disappeared, because on account of the infinite value of dq/dc at $c_1 = 0$, the tail of the frontal band moves infinitely slowly and thus would always be overtaken by any other substance with $c > 0$ (see Fig. 5 of Part IV). The complete separation into two distinct bands

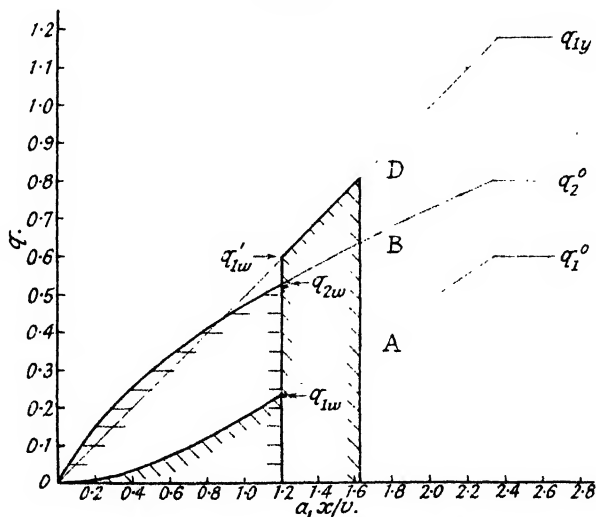

FIG. 5.

Boundary lines of chromatograms calculated for mixed isotherm with the constants $n_1 = n_2 = 2$ and $a_1/a_2 = \frac{1}{2}$. Intermediate case between Figs. 4 and 6.

of two solutes can therefore always be taken as a sign that the strict Freundlich isotherm does not apply to the faster-moving solute at very low concentrations, but that a pseudo-Freundlich isotherm of the type of eqn. (1) applies, which, as has been shown by a similar diagrammatic investigation, always permits separation into two distinct bands.

FIG. 6.

Boundary lines of chromatograms calculated for mixed isotherm with the constants $n_1 = n_2 = 2$ and $a_1/a_2 = \frac{1}{3}$. Note that no pure solute II is separable; consequently no complete separation is attainable.

This conclusion agrees with the experimental findings by Schwab and Jockers (*Z. angew. Chem.*, 1937, 50, 646) that no white zones between coloured bands can be obtained when mixed inorganic solutes are chromatographed on alumina, where isotherms with Freundlich characteristics obtain.

The difference of the chromatograms from those of Langmuir isotherms becomes marked for small separability of the two solutes ($1 > q_1/q_2 > 0.5$) (see Fig. 6). Here the flat portion at the front of the pure tail band of solute II and the discontinuity at this point disappear. On the other hand, there is no longer a point of complete separation, as the curve representing q_1 now runs right back to the top of the chromatographic column ($x = 0$). In this case, solute II cannot even partially be obtained in the pure state, though a certain amount of solute I can be obtained pure at the front boundary.

Between these two extremes lies the intermediate case, $a_1/a_2 = \frac{1}{2}$ (see Fig. 5). Here we have the very rare, and in practice never realised case where a pure rear band can form without a discontinuity at its forward boundary, and where, consequently, the equations (in particular 6 and 7) suggested by Offord and Weiss (*Nature*, 1945, 155, 725), which do not normally hold good, become identical with those of Glueckauf (*ibid.*, 156, 205).

(c) *The Case of $n_1 \neq n_2$.*—It can be shown by a graphical integration (as in Fig. 3) that the two types of chromatographic behaviour as shown in Figs. 4 and 6 will also occur if $n_1 \neq n_2$. As in the case shown in Fig. 4, separation of a pure rear band of solute 2 (with a discontinuity at x_0) is confined to the essential conditions

$$\left[\frac{dc_1}{dq_1} \right]_{q_1=0} > 0 \quad \text{and} \quad \left[\frac{dq_1}{dq_2} \right]_{q_1=0} > 0 \quad . \quad . \quad . \quad (7)$$

This gives the possibility of discussing, not only the case of the isotherm (5a, b), but also the general isotherm of the type

$$c_1 = q_1 \phi(q_1, q_2) \quad c_2 = q_2 \psi(a_1 q_1, a_2 q_2) \quad . \quad . \quad . \quad (8a, b)$$

where ϕ and ψ are any functions, the latter being a symmetrical function with respect to $\alpha_1 q_1$ and $\alpha_2 q_2$. Then

$$\left[\frac{dc_1}{dq_1} \right]_{q_1=0} = \phi(0, q_2) \quad . \quad . \quad . \quad (9)$$

$$\left[\frac{dc_2}{dq_2} \right]_{q_1=0} = \psi(0, q_2) + q_2 \left[\frac{d\psi}{dq_2} \right]_{q_1=0} \quad . \quad . \quad . \quad (10)$$

Equating (9) and (10) results in

$$\left[\frac{c_1}{q_1} \cdot \frac{q_2}{c_2} \right]_{q_1=0} = \xi_0 = 1 + \frac{q_2 \phi^2}{c_2 \psi} \left[\frac{d\psi}{dq_2} \right]_{q_1=0} \quad (11)$$

which, after partial differentiation, leads to

$$\left[\frac{dq_1}{dq_2} \right]_{q_1=0} = \left(\xi_0 - \left[\frac{\partial \log c_2}{\partial \log q_2} \right]_{q_1=0} \right) / \frac{a_1}{a_2} \left(\left[\frac{\partial \log c_2}{\partial \log q_2} \right]_{q_1=0} - 1 \right) \quad (12)$$

As $dq_1/dq_2 > 0$, the condition for complete separability of the solutes is

$$\xi_0 > \left[\frac{\partial \log c_2}{\partial \log q_2} \right]_{q_1=0} \quad (13)$$

A useful application of (12) and (13) will in general be prevented by lack of knowledge of the value of q_{20} . But in the case of the isotherm (5a, b), $[\partial \log c_2 / \partial \log q_2]_{q_1=0}$ is independent of q_{20} and results in

$$\left[\frac{dq_1}{dq_2} \right]_{q_1=0} = a_2(\xi_0 - n_2)/a_1(n_2 - 1) \quad . \quad . \quad . \quad (12a)$$

and in the condition

$$\xi_0 > n_2 > 1 \quad . \quad . \quad . \quad (13a)$$

If, as in the case of Fig. 3, $n_1 = n_2$, ξ_0 has the simple value a_2/a_1 .

For a mixed adsorption isotherm of the type (5a, b) $\log \xi$ is a linear function of $\log \left(\frac{\beta_1}{\beta_2} q_1 + q_2 \right)$, and we can have two different cases, according to whether n_1 (less adsorbed solute) is smaller or larger than n_2 (rear solute). In the first case when $n_1 < n_2$ (or more generally, when ξ increases with decreasing concentration) the condition $\xi_0 > n_2$ is always fulfilled, as development can be continued until ξ is large enough (see Fig. 7a). The separation will be the more efficient the smaller $(q_1^0 + q_2^0)$, as this results in larger values of ξ^0 and ξ_0 . This case behaves thus quite differently from that of the Langmuir isotherm, where separation is accelerated by working at high adsorption densities.

For the second case, when $n_1 > n_2$ (or more generally, when ξ decreases with diminishing concentration) (see Fig. 7b), it is apparent that the separation, which increases with ξ , improves with increasing concentrations of the solutes. If, however, they are not high enough to result in a value of $\xi_0 > n_2$ (or more generally $\xi_0 > \left[\frac{\partial \log c_2}{\partial \log q_2} \right]_{q_1=0}$), which is essential for a clean separation of the solutes, the lowering of the concentrations in the course of the development will result in values of $\xi < 1$, at first for the rear, and eventually also for the front of the band. Thus, in the beginning, solute 1 will separate both in the front and in the rear with enrichment of solute 2 in the middle section of the band. Then, as the concentrations fall in the course of development, separation of solute 1 at the front will come to an end ($\xi_w = 1$) and will even be reversed ($\xi_w < 1$), whereby solute 2 again enters into the pure frontal band of solute 1 and eventually forms a frontal band of pure solute 2.

In this case, it is obviously much more economical to work from the start at such low concentrations that ξ^0 becomes < 1 . This means that the solutes change their subscript and order in the chromatogram, reverting thereby to the case shown in Fig. 7a. It follows from this that chromatography at low enough concentrations will always lead to some kind of separation or enrichment in the case of Freundlich isotherms, though, if $n_1 > n_2$, chromatographic separation at high concentrations may in some cases ($\xi^0 \gg n_2$) result in a faster and more efficient separation,

FIG. 7 a.

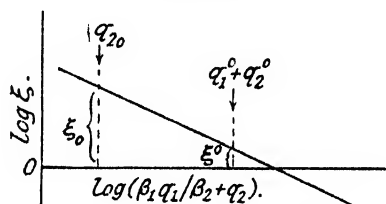

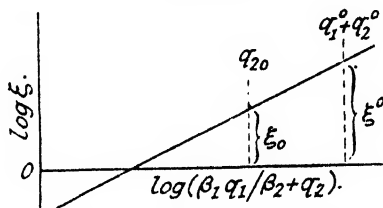

FIG. 7 b.

The separation factor ξ as function of the adsorption density. (a) $n_1 < n_2$: separation improves with the use of lower concentrations. (b) $n_1 > n_2$: separation improves with increasing concentration of the solutes.

particularly, when $c_1^0 \ll c_2^0$, which would result in a relatively large value of c_{20} and hence also of ξ_0 (of same order of magnitude as c_2^0 and ξ^0 respectively; this follows strictly for the Langmuir isotherm, and can be shown to be true for other isotherms by the graphical method).

The first of these conclusions is confirmed by the chromatographic practice, where low concentrations are generally favoured. The second case, where high concentrations improve the separation, and which has apparently so far not been looked for, will be investigated experimentally in due course.

It is also apparent from Fig. 7a and b that, if ξ^0 is identical for two pairs of solutes, where one has $n_1 < n_2$, and the other $n_1 > n_2$, separation will be far easier in the first case where the leading solute has the lower value of n , since during the process of development the value of ξ increases, while the converse is true if the leading solute has the higher n . More generally, it can be said that pairs of solutes with equal ξ can be separated the more easily the smaller the value of n_1/n_2 .

These conclusions might be elaborated more quantitatively, if the proposed binary isotherm (5a, b) were more than a rough working model which, apart from the displacement effect, does not consider mutual influences on each other of the two solutes. The present state of our knowledge concerning binary adsorption isotherms, however, is such that much preliminary work must be directed towards establishing the mutual influence of adsorbed solutes on each other and the mathematical form of mixed isotherms, before further theoretical guidance can be given to the practical chromatographer.

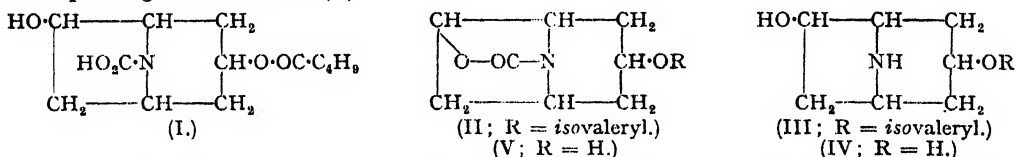

243. The Minor Alkaloids of Duboisia myoporoides. Part IV. Valeroidine.

By WILLIAM MITCHELL and E. M. TRAUTNER.

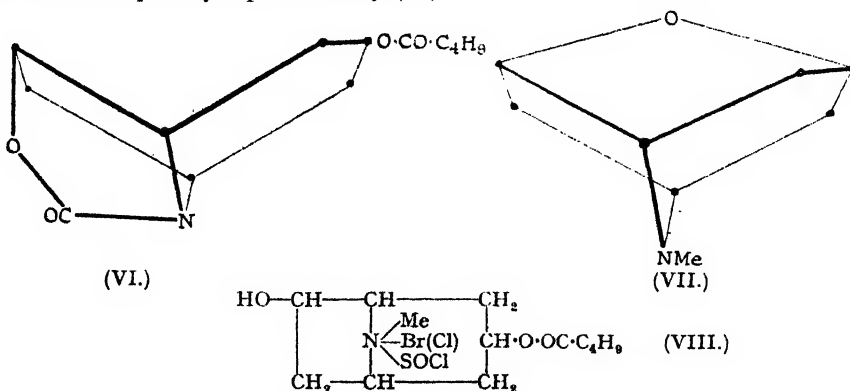

A final structure for valeroidine (*J.*, 1937, 1821; 1940, 1155) is proposed. The product of oxidation with permanganate in acetone is suggested to be an inner urethane, explaining the formation of norvaleroidine on acid hydrolysis. An explanation of the demethylating action of thionyl chloride on valeroidine hydrobromide is also proposed.

VALEROIDINE has been shown (Part I, *J.*, 1937, 1821) to be a monoisovaleryl dihydroxytropane. The parent tropanediol differed from the known 2:3- and 6:7-diols but was shown to be identical with the "dioxytropane" isolated from Peruvian coca leaves by Wolfes and Hromatka (*Merck's Jahresber.*, 1933, 47, 45) and which they suggested to be tropane-3:6-diol. In further work (Part III, *J.*, 1940, 1155) the diacetyl and diisovaleryl derivatives of the tropanediol were prepared and attempts were made to determine the positions of the free and esterified hydroxyl groups in valeroidine. Oxidation with various reagents in acid aqueous solution gave no positive results, but with potassium permanganate in acetone, besides a small yield of norvaleroidine [compare preparation of nortropine from tropine (Willstätter, *Ber.*, 1896, 29, 1580), norscopoline from scopoline (Lubold, *Arch. Pharm.*, 1898, 236, 22), etc.], a new neutral compound was obtained. At that time analysis indicated the formula $C_{13}H_{21}O_4N$ for this compound. On boiling with alcoholic hydrochloric acid the compound was converted into norvaleroidine. This was an unexpected result which could not then be explained.

It is now suggested that the oxidation product is an inner urethane (II) formed by elimination of water from a labile carbamic acid (I) initially produced by oxidation of the *N*-methyl group. Formula (II) requires $C_{13}H_{19}O_4N$, with which later analyses were in closer agreement; it would explain the formation of norvaleroidine (III) by elimination of carbon dioxide on acid hydrolysis. It is probable that the rather ill-defined base obtained, along with isovaleric acid, on alkaline hydrolysis of the oxidation product was a mixture of nortropane-3:6-diol (IV) and the corresponding inner urethane (V).

By analogy with hyoscyamine, hyoscine, etc., it is reasonable to assume that the esterified hydroxyl group is in position 3. On this assumption the comparative stability of the oxidation compound would appear to exclude the possibility that the free hydroxyl group in valeroidine could be attached to carbon 1 (or 5) since this would require the presence of a four-membered urethane ring in the oxidation product. The fairly ready formation of the latter would rather suggest that the free hydroxyl group was attached to carbon 6 (or 7), so that the oxidation product would be spatially represented by (VI).

Wolfes and Hromatka (*loc. cit.*) obtained a 73% yield of "tropene oxide", in which they postulated the presence of an ether linkage, by treating their tropanediol with a mixture of

phosphorus oxychloride and pentachloride. This compound, more correctly termed desoxy-scopoline, can be spatially represented by (VII).

In Part III (*loc. cit.*) attempts to replace the free hydroxyl group in valeroidine by chlorine were also described. These were unsuccessful, but on treating valeroidine hydrobromide (the free base did not give the reaction) with thionyl chloride the curious fact was noted that norvaleroidine was obtained in good yield. It is now suggested that this reaction proceeds through the formation of a labile compound (VIII) which, by loss of methyl chloride (or bromide) and subsequent hydrolysis, yields norvaleroidine (III).

244. Contributions to the Chemistry of Synthetic Antimalarials. Part IV. Hydrazine Hydrolysis and Radical Exchange Reactions of N-Substituted Phthalimides in Relation to the Constitution of the Antimalarial R.63.

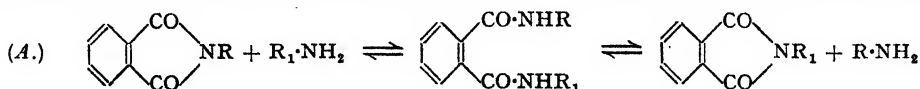

By H. J. BARBER and W. R. WRAGG.

Hydrazine hydrolysis of N-substituted phthalimides has been shown to give the *phthalylhydrazide* salts of the liberated primary amines. Facile radical exchange reactions have been observed between N-substituted phthalimides and substituted aliphatic primary amines. The special case of 8-γ-phthalimidopropylamino-6-methoxyquinoline (II) has been studied in detail. The bearing of these reactions on the composition of R.63 is discussed. The antimalarial activity of R.63 can be accounted for on the basis of the 8-γ-aminopropylamino-6-methoxyquinoline (I) dihydrochloride it contains.

EARLY in 1944, we required 8-γ-aminopropylamino-6-methoxyquinoline (I) in quantity for part of our antimalarial research programme. In preparing this, we encountered certain side reactions relevant to the constitution of the synthetic antimalarial known as R.63 (Robinson and Tomlinson, *J.*, 1934, 1524). This subject had just been reopened by Robinson and his collaborators (*J.*, 1943, 555, 557, 561), who showed that the original constitution ascribed to R.63 was untenable and that most of the feasible alternatives were also excluded. Here was a synthetic drug of confirmed high antimalarial activity (Index 1/64) but of unknown constitution. The hypothesis that the activity was due to the presence, as an impurity, of a small proportion of a still more highly potent antimalarial was an attractive one. The discovery of the side reactions referred to above encouraged this view and indicated the nature of the impurities which might be expected. While our results do not provide absolute proof of the complete composition of R.63 and the source of its activity, they afford strong circumstantial evidence that it is a mixture of a number of products in which the dihydrochloride of (I) is present in sufficient quantity to account for the biological results obtained.

In the synthesis of "antimalarial side chains" by phthalimido-alkylation reactions with substituted aliphatic amines, the following scheme of facile radical exchange has been established:

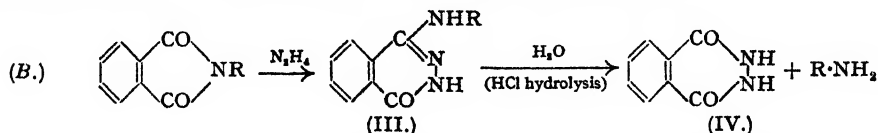

The main factors which determine the end products will be the electronic characteristics of R and R₁, and such relevant properties of their derivatives as solubility in the reagents used or

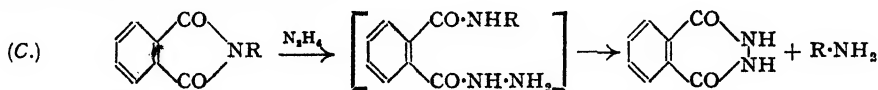

volatility at the reaction temperature. Examples of (A) where R and R₁ = Me, Et, or H have been described recently by Spring and Woods (*J.*, 1945, 625).

The importance to R.63 of the scheme (A) first became apparent while studying the hydrazine hydrate hydrolysis of 8- γ -phthalimidopropylamino-6-methoxyquinoline (II).

A number of workers (Baldwin, *J.*, 1929, 2962; Magidson and Bobishev, *J. Gen. Chem. Russia*, 1938, 8, 912; Beer, *ibid.*, 1939, 9, 2158; Quin and Robinson *J.*, 1943, 555) had previously used this reaction to prepare (I), their method being based on that of Ing and Manske (*J.*, 1926, 2349) who formulated the hydrolysis as follows:

We have found that the sparingly soluble intermediate which separates from the reaction mixture has not the structure (III) ascribed to it tentatively by Ing and Manske, but is in fact the salt of the acidic phthalylhydrazide (IV) with the liberated amine. It is more probable that the course of the reaction is:

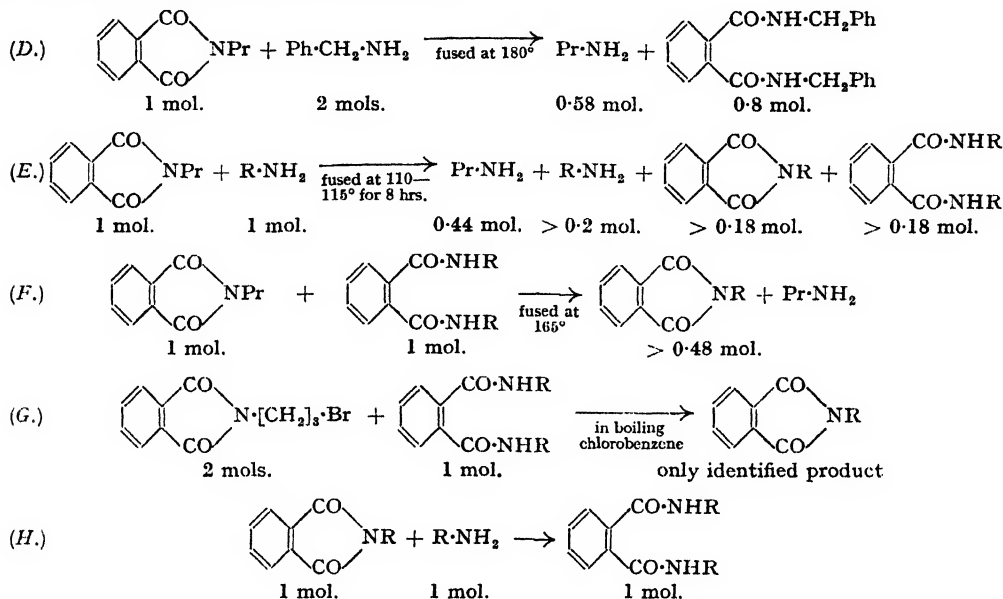

It is clear that this revised conception of the nature of the intermediate (III) suggests modified methods of isolating amines produced by the hydrazine reaction and thus broadens the scope of the method. It is no longer correct to regard the final stage of warming with acid as a hydrolysis of an intermediate such as (III), but as the simple decomposition of a salt by acid. This decomposition can also be effected by alkali, by solvent extraction, or by thermal dissociation. Incidentally, the last procedure provides a ready method of obtaining anhydrous volatile amines where their isolation from the aqueous solutions normally obtained is a matter of some difficulty; application to the laboratory preparation of anhydrous hydrazine will be recorded in a future note.

The intermediate salt we obtained by hydrazine hydrolysis of (II) was dissociated into its components by chloroform extraction and by basification. It was always contaminated by a proportion (dependent on the molar proportion of hydrazine, see Table I) of a secondary product, *phthalobis-[\gamma-(6-methoxy-8-quinolylamino)propyl]amide* (V). This arose by interaction [scheme (A)] between unchanged (II) and free primary amine (I), derived from the partial dissociation in the reaction mixture of its phthalylhydrazide salt. We have studied the acid hydrolysis of the phthalamide (V) under various conditions (Table II) to ascertain the fate of this impurity at the final stage of the Ing and Manske hydrolysis. Under typical conditions complete conversion into an equimolar mixture of (I) and (II) occurred. Thus in a hydrolysis of 1.0 mol. of (II) by the method of scheme (B) using 1.0 mol. of hydrazine hydrate, it can be deduced from Tables I and II that the only impurity present in the reaction product would be approximately 0.075 mol. of the phthalimide (II). This would be removed, together with the phthalylhydrazide, from the aqueous solution of the hydrochloride of the product (I) in the normal course of working up the reaction. The formation of the secondary product (V) can be eliminated by treating (II), dissolved in chloroform-alcohol, with two molar proportions of hydrazine hydrate at room temperature; (I) is then the only product obtained.

We next demonstrated the ready formation of the phthalamide (V) directly from (I) and (II), both in boiling alcohol and by fusion. The facile nature of these changes suggested that similar considerations would apply to the fusion of 8- γ -aminopropylamino-6-methoxyquinoline (I) and phthalo- γ -bromopropylimide—the first stage in the synthesis of R.63. Model experiments with some phthalimides and amines, selected for readier separation of the reaction products, confirmed scheme (A). These experiments are summarised in the following schemes in which R = γ -(6-methoxyquinolyl-8-amino)propyl.

Clearly in the first stage of the preparation of R.63, where phthalo- γ -bromopropylimide (VI) is substituted for phthalo-*n*-propylimide in equation (E), the products of the reaction may be very complex and their separation has proved extremely difficult. The yields of isolated and purified substances must therefore represent much less than the quantities formed in the reaction. From the product of fusing (I) and (VI) by the method of Glen and Robinson (*J.*, 1943, 557) we isolated in a pure state the following: 8- γ -phthalimidopropylamino-6-methoxyquinoline

(II) in 5% of the theoretical quantity, 8- γ -aminopropylamino-6-methoxyquinoline (I) in 10% recovery, and a small quantity of 8- γ -phthalimidopropyl- γ -aminopropylamino-6-methoxyquinoline (VII) monohydrobromide. Since our object was to identify the highly active component responsible *ex hypothesi* for the activity of R.63, we did not attempt quantitative separation of the mixture but turned our attention instead to the synthesis of compounds deduced from the application of scheme (A).

(II) doubtless appeared as the result of a reaction, type (E), from which we inferred that the highly reactive bifunctional compound, γ -bromopropylamine (VIII), was liberated simultaneously with (II). (VIII) could undergo self-condensation to 1:5-diazacyclooctane dihydrobromide (IX) or react in many ways with the various components of the melt. However, both the hydrobromide of (VIII) (Gabriel, *Ber.*, 1888, **21**, 2669) and (IX) (Buhle, Moore, and Wiselogle, *J. Amer. Chem. Soc.*, 1943, **65**, 29) have been found devoid of antimalarial activity.

As molecular proportions of the reagents (I) and (VI) are used in this fusion, the recovery of 10% of unchanged (I) indicated that a similar quantity of phthaloyl- γ -bromopropylamide (VI) might remain unchanged in the fusion product. This would react during the second stage of the preparation of R.63 (treatment of the crude fusion melt with alcoholic hydrazine hydrate followed by warm dilute hydrochloric acid) giving a variety of products. Accordingly, pure (VI) was submitted to the sequence of hydrazine treatment (using various molar proportions of hydrazine) and acid "hydrolysis", but the total basic product derived was always inactive.

Lastly the identification of the "normal" product (VII) of the fusion reaction of (I) and (VI) in the crude melt indicated that some 8- γ -aminopropyl- γ -aminopropylamino-6-methoxyquinoline trihydrochloride would appear in R.63.

Being impressed by the fact that most of the physical change in the fusion reaction took place during the first few minutes, we studied the rate at which the free amino-group of (I) reacted. Table III summarises the results of some Van Slyke nitrogen determinations and shows their relation to the quantities of the various products proved to be present in the melt after various times of fusion. It is noteworthy that the proportion of primary amine (Van Slyke) drops to approximately 30% of its initial value in the first five minutes of fusion and remains at this value even after the seven hours specified by Glen and Robinson (*loc. cit.*).

The complex nature of the first reaction in the preparation of R.63 made it apparent that alcoholic hydrazine hydrate treatment of the crude product could only add to its complexity. We did not therefore proceed to attempt to separate R.63 into its components. However, on the evidence submitted here R.63 would obviously contain at least 10% of unchanged (I), together with a further proportion of (I) (> 5%) formed when the phthalimide (II) present in the melt was treated with hydrazine hydrate. If the Van Slyke figure for N were taken as a

measure of the amine (I) present in the fusion product, a reasonable assumption, then the final R.63 could be calculated to contain > 35% of the possible quantity of the amine (I).

Results obtained in the Biological Laboratories, May & Baker Ltd., indicate that the antimalarial activity and toxicity of R.63 are in general accord with the chemical evidence that upwards of 30% of (I) is present. It should be emphasised, however, that extreme caution is necessary in interpreting the results obtained on a mixture, since the biological properties may be far from additive. The presence of a small proportion of a highly active substance is still not definitely excluded. A fuller discussion of the biological results will appear elsewhere in due course, together with a report on the antimalarial evaluation of phthalobis- $[\gamma$ -(6-methoxy-8-quinolylamino)propyl]amide (V) and 8- γ -phthalamidopropylamino-6-methoxyquinoline.

Addendum.—Publication of this work has been delayed largely because British Patent Application 17071/44, covering the preparation of the phthalamide (V), was placed on the secret list. An independent investigation of the constitution of R.63 has been described recently by Mosher (*J. Amer. Chem. Soc.*, 1946, **68**, 1565). We had, however, followed a somewhat different approach to the problem and overlap in results is restricted to the following points:

Mosher is in agreement that R.63 (as prepared by Robinson and his co-workers) contains considerable 8- γ -aminopropylamino-6-methoxyquinoline (I) dihydrochloride (R.36) and some 4% of 8- γ -phthalimidopropylamino-6-methoxyquinoline (II), although he does not explain how the latter compound was formed. He has demonstrated the presence of a larger proportion (> 20%) of 8- γ' -aminopropyl- γ -aminopropylamino-6-methoxyquinoline trihydrochloride (R.120) than that reported here. Lastly, Mosher foreshadows our elucidation of the nature of the intermediate which separates in the hydrazine hydrolysis of *N*-substituted phthalimides.

A brief summary of the present paper appeared in *Nature* (1946, **158**, 514). Spring and Woods have since added further evidence for scheme (A) (*ibid.*, p. 754).

EXPERIMENTAL.

(Melting points are corrected.)

8- γ -Phthalimidopropylamino-6-methoxyquinoline (II).—8-Amino-6-methoxyquinoline (696 g.) (Barber and Wragg, *J.*, 1946, 612) was refluxed with 0.5 molar proportion of phthalo- γ -bromopropylimide (536 g.) in chlorobenzene (2 l.) for 12 hours. After a short delay, 8-amino-6-methoxyquinoline hydrobromide commenced to separate. This salt (404 g.; 76%) was collected from the cold reaction mixture and the filtrate diluted with alcohol (6 l.); 8- γ -phthalimidopropylamino-6-methoxyquinoline then separated as yellow felted needles. The product was collected after 24 hours, washed with light petroleum (2 l.)-alcohol (750 c.c.), and dried at 40°/11 mm., giving 403 g. (56%), m. p. 99–101°. The chlorobenzene-alcohol liquors were treated with excess of concentrated hydrochloric acid, and the precipitated orange hydrochloride was removed and washed with alcohol (500 c.c.). The damp salt (344 g.) was suspended in boiling alcohol (5 l.) and treated with a small excess of concentrated ammonia. 8- γ -Phthalimidopropylamino-6-methoxyquinoline (104 g.) crystallised, making a total yield of 70%. No 8-bis-(γ -phthalimidopropyl)amino-6-methoxyquinoline was obtained as a by-product under these conditions (cf. Glen and Robinson, *loc. cit.*; Mosher, *loc. cit.*).

8- γ -Aminopropylamino-6-methoxyquinoline (I).—(a) *Hydrolysis of (II) in cold chloroform-alcohol using 2.25 mols. of hydrazine hydrate.* 8- γ -Phthalimidopropylamino-6-methoxyquinoline (7.22 g.) dissolved in chloroform (50 c.c.) and alcohol (50 c.c.) was treated with hydrazine hydrate (4.5 c.c., 50% w/v aqueous solution). After 3 hours at room temperature a gelatinous white precipitate began to separate. After 4 days the solvents were removed at 40°/20 mm. and the residue shaken mechanically (2 hours) with a mixture of 2*N*-ammonia (30 c.c.), water (40 c.c.), and chloroform (70 c.c.). A small quantity of insoluble material (*ca.* 0.5 g.) was dissolved separately by warming with chloroform-ammonia solution and returned to the main bulk. The chloroform layer (A) was extracted with four portions of *N*-acetic acid (20 c.c.) which were bulked, basified with concentrated ammonia, and then exhaustively extracted with ether. This extract on distillation in a bulb tube (air-bath at 180°) at 0.01 mm. gave 8- γ -aminopropylamino-6-methoxyquinoline (4.1 g., 89%), n_D^{25} 1.637, converted into carbamate derivative, m. p. 113–116°. The chloroform (A) was evaporated to dryness, leaving a negligible dark red residue (0.2 g.). The aqueous ammoniacal layer, precipitated with concentrated hydrochloric acid, yielded 2.98 g. (92%) of phthalylhydrazide, m. p. 342–344°.

(b) *Hydrolysis of (II) in boiling alcohol with various proportions of hydrazine hydrate.* Hydrazine hydrate (40 c.c., 50% w/v aqueous solution; 0.8 mol.) was added to a solution of 8- γ -phthalimidopropylamino-6-methoxyquinoline (180 g.) in boiling alcohol (1.5 l.) and the mixture refluxed for 3 hours. The alcohol was removed under reduced pressure from the suspension of cream insoluble product, and the residue vigorously shaken with 2*N*-ammonia (500 c.c.), diluted with water (1 l.), and chloroform (2.5 l.). The aqueous alkaline layer was separated and acidified with concentrated hydrochloric acid; phthalylhydrazide separated (56 g.), m. p. 342–344°.

The chloroform layer was concentrated under reduced pressure to 700 c.c. and diluted with an equal volume of dry ether. Phthalobis- $[\gamma$ -(6-methoxy-8-quinolylamino)propyl]amide (V) separated (44 g.), m. p. 170–174°, crystallising from chloroform-methanol as tiny brown needles, m. p. 177–179° (Found: C, 68.7; H, 6.3; N, 14.0; OMe, 11.0; *M* (ebulliscope in chloroform), 600. $C_{24}H_{24}O_4N_4$ requires C, 68.9; H, 6.1; N, 14.2; OMe, 10.5%; *M*, 592). (V) was converted into the hydrochloride, m. p. 208–210° by treatment of a warm solution in chloroform-methanol with concentrated hydrochloric acid

(Found: N, 12.6; Cl, 10.6. $C_{13}H_{11}O_4N_3 \cdot 2HCl$ requires N, 12.6; Cl, 10.7%). This hydrochloride was readily reconverted into the base by suspension in a large volume of cold water.

The liquors from the separation of crude (V) above were evaporated to dryness under reduced pressure and the oily residue taken up in dry ether (1 l.). Carbon dioxide was passed, very slowly at first, into the filtered bright ethereal solution, precipitating the carbamate derived from (I) (63 g.) as a white powder, m. p. 112–114° [Found: C, 64.2; H, 7.0; N, 16.8. $(C_{13}H_{11}ON_3)_2CO_2$ requires C, 64.0; H, 6.76; N, 16.6%]. When a solution of the carbamate in warm methanol was treated with a small excess of concentrated hydrochloric acid the corresponding dihydrochloride, crystallising from methanol-ether in short orange needles, was obtained (96%). Drying over potash in a vacuum gave the anhydrous salt (cf. Beer, *loc. cit.*), m. p. 244–246° with slight previous shrinking from about 230° [Purification of many samples failed to give material, m. p. 251–252° (cf. Baldwin, *loc. cit.*; Beer, *loc. cit.*] (Found: N, 13.7; Cl, 23.5. Calc. for $C_{13}H_{11}ON_3 \cdot 2HCl$: N, 13.8; Cl, 23.4%). The free base (I) was prepared in 96% yield by dissolving the carbamate in a small excess of dilute hydrochloric acid at 80°, removing any dissolved carbon dioxide with a rapid stream of nitrogen for 10 minutes, basifying with concentrated aqueous ammonia, and extracting the liberated base with ether. Distillation of the residue on removal of the ether gave (I) as a single fraction, b. p. 160°/0.01 mm., a viscous yellow oil, n_D^{25} 1.637 (Found: C, 67.5; H, 7.4; N, 18.05. Calc. for $C_{13}H_{11}ON_3$: C, 67.5; H, 7.4; N, 18.2%), stored under an atmosphere of hydrogen. On long standing this sample solidified to a waxy solid, m. p. 37–38°.

In the experiment below where unchanged phthalimide (II) was recovered, this was isolated from the ethereal liquor after the precipitation and removal of the carbamate of (I).

The above experimental details exemplify the method of separation employed to obtain the results summarised in Table I.

TABLE I.

Reaction of the phthalimide (II) with hydrazine hydrate.

[R = γ -(6-methoxyquinolyl-8-amino)propyl.]

The products obtained, when the phthalimide (V) was treated with aqueous hydrochloric acid under various conditions, were separated and identified by means very similar to those described in the case of Table I. These results are summarised in Table II.

Model Experiments.—(a) *Exemplification of scheme (C) where R = benzyl.* Phthalobenzylimide (23.7 g.) was suspended in alcohol (200 c.c.), boiling under reflux, and hydrazine hydrate (10 c.c., 50% w/v aqueous solution; 1.0 mol.) added. After 2 hours the reaction mixture was cooled and the white crystalline product collected (21.3 g.). After being dried in the steam-oven for 1 hour this material analysed for the anhydrous phthalylhydrazide (IV) salt of benzylamine, m. p. 326–346° (Found: C, 66.8; H, 5.4; N, 15.5. $C_{18}H_{15}O_2N_3 \cdot C_7H_7N$ requires C, 67.0; H, 5.6; N, 15.6%). 2 G. of this salt were dissociated by one crystallisation from alcohol (200 c.c.); phthalylhydrazide alone separated, m. p. 342–346° (Found: C, 59.6; H, 4.0; N, 17.5. Calc. for $C_{18}H_{15}O_2N_3$: C, 59.3; H, 3.7; N, 17.3%). Dissociation was also effected by heating the salt (5.4 g.) at 120–140°/0.05 mm. for 3 hours. The

distillate, collected in a solid carbon dioxide-acetone cooled receiver, was anhydrous benzylamine (1.66 g.; 78%). (Found: *M*, by titration, 107. Calc. for C_7H_9N : *M*, 107).

(b) *Exemplification of scheme (D)*. Phthalo-*n*-propylimide (10 g.) and benzylamine (11.4 g.; 2 mol.) were fused in a distillation flask fitted with a Vigreux column. The melt was slowly heated to 180°. The distillate (b. p. 49°), collected in a cooled receiver, was anhydrous propylamine (1.8 g., 59%) contaminated by a small proportion of benzylamine. The residue, crystallised twice from chloroform, was phthalo-*NN'*-dibenzylamide, m. p. 176—178° (Tingle and Lovelace, *Amer. Chem. J.*, 1907, **38**, 651, give m. p. 178—179°).

(c) *Exemplification of scheme (E)*. 8- γ -Aminopropylamino-6-methoxyquinoline (2.2 g.) was fused with phthalo-*n*-propylimide (1.89 g.) for 8 hours at 110—115°. The *n*-propylamine (44%) evolved from the melt was removed in a slow stream of hydrogen which was subsequently scrubbed with standard acid. The fusion product was dissolved in methanol (40 c.c.). On cooling, the phthalamide (V) separated, 1.06 g., m. p. 157—171°. Recrystallisation from chloroform-methanol gave 0.9 g., m. p. 176—178°; mixed m. p. with authentic material was 175—178°. On standing, the liquors from the crude phthalamide (V) precipitated the phthalimide (II) (0.64 g.) (*A*), m. p. 97—99°, characterised by mixed m. p. 100—101° with authentic material after recrystallisation from methanol. The methanol liquors from (*A*) were concentrated, and the residue dissolved in ether was treated with carbon dioxide, precipitating the carbamate of the amine (I) (0.5 g.), m. p. 112—116°.

(d) *Exemplification of scheme (F)*. An equimolar mixture of the phthalamide (V) (5.9 g.) and phthalo-*n*-propylimide (1.9 g.) were fused at 165° for 1 hour, during which time *n*-propylamine was evolved. The fusion product was dissolved in alcohol (50 c.c.) from which 3.5 g. (48%) of bulky yellow needles separated, m. p. 84—100°. Recrystallisation from alcohol gave the phthalimide (II) (3.2 g.), m. p. 99—101°, characterised by mixed m. p. with an authentic sample.

(e) *Exemplification of scheme (G)*. The phthalamide (V) (1.18 g.) was refluxed for 10 hours in chlorobenzene (20 c.c.) with phthalo- γ -bromopropylimide (1.07 g.). The hydrochloride precipitated from the mixture by alcoholic hydrogen chloride was crystallised twice from alcohol and then converted in aqueous methanol into the base, long bulky yellow needles from methanol (0.2 g.), m. p. 99—101°, shown to be the phthalimide (II) by mixed m. p.

(f) *Exemplification of scheme (H)*. (i) Equimolar proportions of the amine (I) (2.31 g.) and the phthalimide (II) (3.61 g.) were refluxed for 1 hour in alcohol (70 c.c.). The total product which separated on cooling was crystallised from chloroform-ether; the phthalamide (V) (2.05 g.) was thus obtained, m. p. 173—176° (identity confirmed by mixed m. p.).

(ii) A theoretical yield of the phthalamide (V) was obtained when the above reaction was carried out by fusion for 1 hour at 115°.

(iii) A 70% yield of the phthalamide (V) was similarly obtained from the fusion of the amine (I) (5.1 g.; 2 mols.) and phthalic anhydride (1.5 g.) at 115° for 1 hour.

(iv) A theoretical yield of phthalo-*NN'*-dibenzylamide was similarly obtained by fusion of equimolecular quantities of phthalobenzylimide and benzylamine at 120° for 1½ hours.

First Stage of the Preparation of R.63. Separation of the Reaction Products of the Fusion of 8- γ -Aminopropylamino-6-methoxyquinoline (I) with Phthalo- γ -bromopropylimide (VI).—The identification of unchanged (I) and the phthalimide (II) as products of this reaction has been confirmed at least twice, both after 15 minute and 7 hour fusions. The following are typical experiments:

(a) *Method of fusion*. Equimolar proportions of (I) (6 g.) and (VI) (7 g.) were mixed by rotation of the reaction flask, closed by a calcium chloride tube, and immersed in an oil-bath at 115°. The mixture fused to a mobile liquid which rapidly thickened to a red-brown glass.

(b) *Isolation of 8- γ -phthalimidopropylamino-6-methoxyquinoline (II)*. The glassy product from a 7 hour fusion as in (a) was dissolved in glacial acetic acid (15 c.c.) with mechanical shaking (10 hours). The orange-brown precipitate which separated was filtered from the viscous red liquor, washed with three portions of glacial acetic acid (5 c.c.) and then ether, giving 1.7 g., m. p. 190—200°. This was repeatedly recrystallised from methanol until the orange hydrobromide obtained (0.98 g.), m. p. 214—220°, was sufficiently pure to yield 0.3 g. of phthalimide (II), m. p. 102—103° (identity confirmed by mixed m. p.), on treatment with ammoniacal methanol. By dilution with water and recrystallisation of the precipitate, a further 0.1 g., m. p. 100—103°, of the phthalimide (II) was isolated from the mother liquor. The original acetic acid liquors were stored at 0° (2 days) when a further 0.6 g. of orange material separated. This crystallised from methanol giving 0.35 g., m. p. 220—225°, which on conversion into the base (0.09 g.) was characterised by mixed m. p. 101—103° as the phthalimide (II).

(c) *Isolation of 8- γ -aminopropylamino-6-methoxyquinoline (I)*. The fusion product from a 7 hour reaction as (a) was dissolved with mechanical shaking in chloroform (50 c.c.). The solution was shaken with 2*N*-ammonia (12 c.c.) and water (20 c.c.). The chloroform layer was then extracted with four 2 c.c. portions of 2*N*-acetic acid in water (20 c.c.) until the last extract was acid (litmus). The combined extracts were counter-extracted (chloroform) and then basified slowly with 2*N*-ammonia in the presence of ether (500 c.c.). The aqueous layer was then made strongly alkaline with concentrated ammonia and saturated with salt. The dried (K_2CO_3) ether layer was evaporated and distilled in a bulb tube (air-bath up to 200°) at 0.01 mm. About half the residue distilled, yielding a light brown oil, 2.0 g., n_D^{20} 1.631. This was taken up in ether and converted into the carbamate of (I) (0.7 g., 10% recovery), m. p. 100—108°, decomposing in a bulb tube to give pure (I) (0.5 g.), n_D^{20} 1.636, reconverted into carbamate derivative, m. p. 109—115° (mixed melting point with authentic material 113—116°).

(d) *Isolation of 8- γ' -phthalimidopropyl- γ -aminopropylamino-6-methoxyquinoline (VII)*. The product from a 7 hour fusion, as (a) was dissolved in pyridine (25 c.c.). The brown oil precipitated with water (300 c.c.) was twice extracted by boiling with a supernatant layer of ether (100 c.c.). The residue separated by decantation was dissolved in methanol (100 c.c.) and diluted with an equal volume of ether. The precipitated gum solidified on standing. The solid was collected and recrystallised from methanol, forming long rectangular light brown plates, m. p. 174—177°, which proved to be 8- γ' -phthalimidopropyl- γ -aminopropylamino-6-methoxyquinoline monohydrobromide (Found: C, 57.4; H, 5.1; N, 11.0; Br, 16.8. $C_{24}H_{28}O_3N_4.HBr$ requires C, 57.7; H, 5.4; N, 11.2; Br, 16.1%). We con-

cluded that this product was not 8- γ -aminopropylamino-6-methoxy-1- γ -phthalimidopropylquinolinium bromide, or 8- γ -aminopropyl- γ -phthalimidopropylamino-6-methoxyquinoline hydrobromide, compounds of the same empirical formula, because no primary amine group could be detected in a micro-Van Slyke determination, for which we are indebted to Miss P. Garwood of Imperial College, S.W. 7.

(e) *Typical analytical experiment in outline.* The product from a 15 minute fusion, as in (a), was dissolved in alcohol (50 c.c.). The solution was slowly added to well-stirred ether (300 c.c.). The milky product was shaken with 100 c.c. water and then extracted with *n*-hydrochloric acid (20 c.c.). The bright ether layer was dried (K_2CO_3) and evaporated to give 1.3 g. (18% recovery) of unchanged phthalo- γ -bromopropylimide (VI), m. p. 69–72°. The bulked aqueous extracts were basified with 50% sodium hydroxide and the total bases taken up into chloroform (150 c.c.) (A). This was extracted with 2*N*-acetic acid (25 c.c.) in water (50 c.c.), and the extracted material taken as base into ether. This dried (K_2CO_3) ether extract yielded the carbamate of (I) (1.0 g., 16% recovery). The chloroform (A) was next removed and the residue converted into hydrochloride (B) which was crystallised from alcohol. The insoluble hydrochloride of the phthalimide (II) (1.6 g., 15%) was first obtained. This was repeatedly crystallised from methanol, and, when sufficiently pure, converted into base confirmed to be (II) by m. p. and mixed m. p. The more soluble hydrochloride in the mixture (B) was crystallised from alcohol-ether many times without a pure substance being definitely characterised, although a N : Cl ratio of 2.07/1 indicated 8- γ' -phthalimidopropyl- γ -aminopropylamino-6-methoxyquinoline (VII) dihydrochloride.

The above results are summarised in Table III, together with Van Slyke estimations for primary amino-group on the products of fusions [as (a)] of varying duration.

TABLE III.

R.63 fusion. Progress of reaction.

Duration of fusion.....	Nil.	5 mins.	15 mins.	7 hrs.
Van Slyke estimation of N present as primary amino-group (%)	6.4, 6.3*	2.1	—	2.4
Proportion of amine (I) recovered unchanged (%)	—	—	16	10
Proportion of phthalimide (VI) recovered unchanged (%)	—	—	18	—
Proportion of theoretically possible phthalimide (II) actually isolated as crude hydrobromide (%)	—	—	15	22†

* Amine (I) requires 6.06%.

† 5% as pure base.

Preparation of R.63 for Antimalarial Test.—The procedure of Glen and Robinson (*loc. cit.*) was exactly followed [Found on our sample of R.63 : N as primary amino-group (Van Slyke), 4.85. Calc. for amine (I) dihydrochloride, 4.6. Calc. for 8- γ' -aminopropyl- γ -aminopropylamino-6-methoxyquinoline trihydrochloride, 3.5%].

8-*Bis-(γ -phthalimidopropyl)amino-6-methoxyquinoline.*—8- γ -Phthalimidopropylamino-6-methoxyquinoline (20 g.) was fused with exclusion of moisture with phthalo- γ -bromopropylimide (32 g.) for 12 hours at 120°. The red glassy product was dissolved in methanol (200 c.c.), and an orange hydrobromide (20 g.) crystallised out. This was converted into base in methanol-2*N*-ammonia. 8-*Bis-(γ -phthalimidopropyl)amino-6-methoxyquinoline* crystallised from pyridine-methanol, m. p. 165–167° (13 g., 43%) (cf. Quin and Robinson, *loc. cit.*).

8- γ -*Phthalamidopropylamino-6-methoxyquinoline.*—8- γ -Phthalimidopropylamino-6-methoxyquinoline (20 g.) was added to a boiling solution of potassium hydroxide (13.8 g.) in alcohol (275 c.c.). After 30 minutes the mixture was cooled to 0° and almost neutralised with 2*N*-hydrochloric acid. The precipitated salt was just dissolved by adding water (200 c.c.) and the alcohol removed at 30 mm. The remaining liquor (charcoaled) was just acidified (litmus) cold with glacial acetic acid. The precipitated *product* was crystallised from aqueous methanol and dried over phosphoric oxide at 10 mm. (Found : C, 63.7; H, 6.1; N, 10.7; *M*, by titration, 390. $C_{21}H_{21}O_4N_3 \cdot H_2O$ requires C, 63.5; H, 5.8; N, 10.6%; *M*, 397). The loss in weight at 100° on this hydrated acid (Found : 9.2. $C_{21}H_{21}O_4N_3 \cdot H_2O$ requires 4.54%) indicated that both dehydration and ring closure had occurred, giving the phthalimide (II). This was confirmed by m. p. 101–103° and mixed m. p. 101–104° with authentic material after one crystallisation from methanol.

We are indebted to Mr. S. Bance, B.Sc., A.R.I.C., for the semi-microanalyses, and to the Directors of Messrs. May and Baker Ltd. for permission to publish these results.

245. The Constitution of Copæne.

By LINDSAY H. BRIGGS and WILLIAM I. TAYLOR.

The constitution of copæne has been elucidated on the basis of the following sequence of reactions. Perbenzoic acid yields the oxide, converted by methylmagnesium iodide into the corresponding methylcarbinol which after dehydration and dehydrogenation furnishes the known compound, 1 : 6 : 7-trimethyl-4-isopropynaphthalene.

THE tricyclic sesquiterpene copæne is a comparatively rare constituent of essential oils, and so far it has only been detected in the oils of *Oxystigma mannii* (Schimmel's Report, 1914, April, p. 48), *Sindora wallichii* (Henderson, McNab, and Robertson, J., 1926, 3077), *S. inermis* (Huzita, J. Chem. Soc. Japan, 1941, 62, 431), *Dysoxylum fraserianum* (Penfold, J. Proc. Roy. Soc. New South Wales, 1928, 61, 337) and *Cedrela toona* (Pillai and Rao, J. Soc. Chem. Ind., 1931, 50, 220r). More recently it has been identified by Briggs and Sutherland (forthcoming publication) in the oil of the New Zealand tree, *Phyllocladus trichomanoides*, the source for the present investigation.

From the molecular refraction, the formation of a dihydro-derivative, and the oxidation by ozone or potassium permanganate to a monobasic ketonic acid, copæne ketonic acid, $C_{15}H_{24}O_2$, copæne was shown by Semmler and Stenzel (*Ber.*, 1914, 47, 2555) to be tricyclic with one ethylene linkage. Since it also gave *l*-cadinene dihydrochloride with hydrogen chloride it must contain the cadinene skeleton and a cyclopropane ring, later confirmed by Henderson *et al.* (*loc. cit.*) by dehydrogenation with sulphur to cadalene. By further oxidation of copæne ketonic acid with sodium hypobromite, Semmler and Stenzel obtained a dibasic acid, copæne-dicarboxylic acid, $C_{12}H_{18}O_4$ (*vide infra*), apparently by the elimination of an isopropyl group. The provisional formula (I) suggested by Semmler and Stenzel was changed to (II) by Henderson *et al.* in view of the structure (III) proposed by Ruzicka and Stoll (*Helv. Chim. Acta*, 1924, 7, 84) for cadinene.

In view of the revised structure for cadinene (IV) put forward on a firm experimental basis by Campbell and Soffer (*J. Amer. Chem. Soc.*, 1942, 64, 417) that of copæne also required revision.

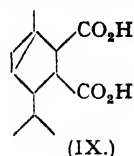

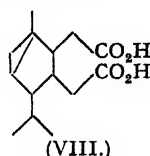

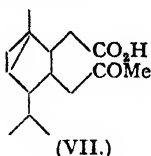

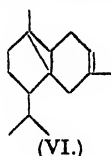

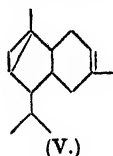

The position of the double bond at C_6-C_7 in copæne has now been established by the method used by Ruzicka and Sternbach (*Helv. Chim. Acta*, 1940, 23, 124) for determining the position of the double bond in *d*-pimaric acid and applied by Campbell and Soffer (*loc. cit.*) and Soffer, Steinhardt, Turner, and Stebbins (*J. Amer. Chem. Soc.*, 1944, 66, 1520) for the constitution of cadinene and isozingiberene respectively.

Copæne was converted quantitatively into the oxide by the action of perbenzoic acid. On distillation in high vacuum, however, three fractions were obtained, indicating that some isomerisation to the ketone or fission of the cyclopropane ring had occurred. Since the isomeric ketone should give the same product ultimately as the oxide, the combined distillate was treated with excess of methylmagnesium iodide and the resultant methylcarbinol dehydrated with formic acid. Dehydrogenation with palladised charcoal failed to yield an aromatic hydrocarbon, but this was formed with selenium. The dehydrogenation products, after being washed with alkali, were distilled, small fractions being taken off empirically and converted into picrates. From two fractions the picrate of 1 : 6 : 7-trimethyl-4-isopropynaphthalene was obtained after repeated crystallisation, the purest specimen having m. p. 121–122°. Campbell and Soffer (*loc. cit.*) record m. p. 122–123° for their synthetic material. The double bond in copæne must therefore be in the 6–7 position.

From the alkaline washings of the dehydrogenation product a crystalline naphthol, $C_{15}H_{18}O$, was obtained (picrate, trinitrobenzoate) which is probably the previously unknown 7-hydroxy-1 : 6-dimethyl-4-isopropynaphthalene arising from the dehydrogenation of unmethylated copæne oxide or the isomeric ketone. We hope to report later on this compound.

Since copæne forms *l*-cadinene dihydrochloride with hydrogen chloride, the three-membered ring must have one point of attachment at C_1 and the other at C_2 (V) or C_{10} (VI). If the latter, then dehydrogenation should yield an azulene as well as cadalene as in the case of ledene

(Komppa and Nyman, *Compt. rend. Trav. Lab. Carlsberg*, 1938, 22, 272) or azulene alone as in aromadendrene (Radcliffe and Short, *J.*, 1938, 1200). Since no trace of azulene is obtained from copæne the three membered ring must be at C₁-C₃ and copæne must be formulated as (V).

The copæne ketonic acid, C₁₅H₂₄O₃, of Semmler and Stenzel must now be revised to (VII), and the dibasic acid, copænedicarboxylic acid, obtained on sodium hypobromite oxidation, is more probably the normal product (VIII), C₁₄H₂₂O₄, rather than (IX) C₁₂H₁₈O₄, with which, however, the analytical figures agree.

EXPERIMENTAL.

The copæne used in these experiments was repeatedly fractionated, finally through a 20 plate column, and then had the following constants: b. p. 114–114.5°/10 mm.; d_4^{20} 0.9055 (constant); n_D^{20} 1.4880–1.4895; $[\alpha]_D^{25}$ –0.44° to +1.20°; it had been identified by Briggs and Sutherland (*loc. cit.*) by the formation of *l*-cadinene dihydrochloride with hydrogen chloride, dehydrogenation to cadalene with palladised charcoal, and oxidation to copæne ketonic acid, characterised as the semicarbazone, m. p. 222°, and the semicarbazone of its methyl ester, m. p. 194–196°.

Copæne Oxide.—A solution of copæne (11.1 g.) in chloroform (200 c.c.) was added to a twofold excess of perbenzoic acid in chloroform (300 c.c.) at 6° and left overnight. Titration of an aliquot portion against standard thiosulphate solution after addition of potassium iodide then showed that reaction was complete. The chloroform solution, after being washed with sodium carbonate and sodium thiosulphate solutions, yielded a viscous colourless oil (11.9 g.), separated by distillation into the following fractions: (1) b. p. 112–120°/0.5 mm., 4.09 g.; (2) b. p. 95–105°/0.03 mm., 2.24 g.; (3) b. p. 127–130°/0.05 mm., 1.37 g.

Methylation and Dehydration.—The combined fractions (7.3 g.) in dry ether (30 c.c.) were slowly added to an ethereal solution of methylmagnesium iodide (3 molal excess), and after the first action had ceased the mixture was refluxed for 30 hours. After decomposition with saturated ammonium chloride solution the reaction mixture was extracted with ether, and the extract, after being washed with brine containing sodium carbonate, then with water, and dried (Na₂SO₄), yielded on distillation of the ether a syrupy product (6.43 g.) in 82% yield. This was boiled under reflux with formic acid (15 c.c.) for 15 minutes and, after addition of water, the product was isolated through light petroleum; yield 5.97 g.

Dehydrogenation.—The dehydrated oil (1.43 g.) and selenium (2.08 g.) were heated slowly to 200° until water ceased to be evolved, the temperature was then maintained at 220° for 16 hours and at 300° for a further 9 hours. The product was extracted with light petroleum, and the solution washed with sodium hydroxide solution and water, and dried; after removal of the solvent 0.864 g. of a slightly fluorescent oil was obtained. On distillation at 10 mm. (bath temperature 120°) five fractions were obtained weighing successively 0.2286 g., 0.0987 g., 0.0736 g., 0.1466 g., and 0.0411 g., leaving 0.2090 g. of a residual black tar. The first three fractions failed to yield a pure picrate. From the fourth fraction a crude red picrate (200 mg.) was obtained, m. p. 95°, which after six crystallisations from methyl alcohol furnished 8 mg. of long needles of constant m. p. 121–122° (Found: C, 60.10; H, 5.47; N, 9.35. Calc. for C₁₅H₂₀, C₈H₃O₂N₃: C, 59.85; H, 5.25; N, 9.52%). From the mother liquors of the fourth fraction a small amount of impure cadalene picrate, m. p. 110–111°, was isolated which on being mixed with an authentic specimen softened at 100° and melted at 109–112°. The fifth fraction yielded the impure picrate of 1:6:7-trimethyl-4-isopropyl-naphthalene, m. p. 117–118°, undepressed by a pure specimen obtained from the fourth fraction.

From the alkaline washings of the dehydrogenation product a crude *naphthol* was obtained on acidification and purified by sublimation at 100°/0.01 mm.; yield 30 mg. The product recrystallised from methyl alcohol as woolly needles, m. p. 116° (Found: C, 83.54, 83.58; H, 8.50, 8.66. C₁₅H₁₈O requires C, 84.05; H, 8.46%). The dark red picrate separated from methyl alcohol in short needles, m. p. 139°, and the bright red trinitrobenzoate similarly in long needles, m. p. 139–140°.

The analyses are by Drs. Weiler and Strauss, Oxford.

We are indebted to the Chemical Society and the Australian and New Zealand Association for the Advancement of Science for grants, and to Dr. L. M. Cooke for Monel metal gauze used in the fractionating column. One of us (W. I. T.) is indebted for a Duffus Lubecki Scholarship.

246. Some Derivatives of D-Galacturonic Acid.

By J. K. N. JONES and M. STACEY.

The synthesis is described of some derivatives of D-galacturonic acid, in particular 2-methyl α -methyl-D-galacturonoside methyl ester. This compound was oxidised to 2-methyl galactosaccharic acid (2-methyl mucic acid) a useful reference compound, while under stronger oxidising conditions some demethylation occurred with formation of galactosaccharic acid (mucic acid).

In addition to its widespread occurrence in plant gums and pectins, D-galacturonic acid forms a constituent of certain bacterial polysaccharides, e.g., the Type I *pneumococcus* specific polysaccharide (Heidelberger, Goebel, and Avery, *J. Exp. Med.*, 1925, 42, 701), and the polysaccharide of *Coccidioides immitis* (Hassid, Baker, and McCready, *J. Biol. Chem.*, 1943, 149, 303).

It was necessary to synthesise partly methylated derivatives of D-galacturonic acid to serve as reference compounds in determination of bacterial polysaccharide structure. D-Galacturonic acid, obtained both by synthesis from D-galactose (Stacey, *J.*, 1939, 1529) and from citrus pectin by enzymic degradation, was converted into α -methyl-D-galacturonoside methyl ester [which has the pyranose structure (Levene and Kreider, *J. Biol. Chem.*, 1937, 120, 597)] by boiling it with 1% methanolic hydrogen chloride for 8 hours. Treatment of this ester for 15 hours with acetone containing either 0.4% hydrochloric acid or anhydrous copper sulphate with a trace of concentrated sulphuric acid converted it into 3:4-monoacetone α -methyl-D-galacturonoside methyl ester (m. p. 107°; monohydrate, m. p. 70°).

This product was transformed on methylation with silver oxide and methyl iodide into the syrupy 2-methyl derivative. On being kept in a moist atmosphere the syrup crystallised in the form of its monohydrate. Removal of the acetone groups gave syrupy 2-methyl α -methyl-D-galacturonoside methyl ester (amide, m. p. 174°) which on being oxidised with nitric acid under moderate conditions gave 2-methyl galactosaccharic acid, a liquid (amide, m. p. 200°). Under more drastic oxidation conditions with nitric acid there was observed an unusual case of demethylation with production of free galactosaccharic acid in fairly good yield; cf. Anderson and Otis (*J. Amer. Chem. Soc.*, 1930, 52, 4462), who effected the removal of non-glycosidic methyl residues from a mesquite gum by means of 72% sulphuric acid.

EXPERIMENTAL.

D-Galacturonic Acid.—This was prepared both from citrus pectin by the action of the enzyme, "Pectinol IOM," and from D-galactose by the synthetic method of Stacey (*loc. cit.*).

α -Methyl-D-galacturonoside Methyl Ester.—D-Galacturonic acid (5 g.) was boiled for 8 hours with 1% methanolic hydrogen chloride. The solution, neutralised with lead carbonate, was filtered and evaporated under diminished pressure to a syrup which rapidly crystallised. When recrystallised from methyl alcohol-acetone the substance had m. p. 147°, yield 50%, $[\alpha]_D^{20} +128^\circ$ (c, 1.0 in water); cf. Morell and Link (*J. Biol. Chem.*, 1933, 100, 385).

3:4-Monoacetone α -Methyl-D-galacturonoside Methyl Ester.—(a) α -Methyl-D-galacturonoside methyl ester (1.2 g.) was shaken with acetone (50 c.c.) containing hydrogen chloride (0.2 g.) for 15 hours. The clear solution was poured into aqueous sodium hydrogen carbonate and the 3:4-monoacetone derivative extracted with chloroform. The extracts were dried ($MgSO_4$), and the filtered solution was evaporated in a vacuum. The compound (1.1 g.) had m. p. 107° (Found: C, 50.1; H, 6.8; OMe, 23.4. $C_{11}H_{18}O_7$ requires C, 50.4; H, 6.9; OMe, 23.6%).

(b) α -Methyl-D-galacturonoside methyl ester (5 g.) was shaken for 12 hours in acetone (200 c.c.) containing anhydrous copper sulphate (5 g.) and concentrated sulphuric acid (0.5 g.). The acid was neutralised with copper carbonate, and the filtered solution on evaporation yielded a crystalline product. When recrystallised from acetone-ligroin the product (4.5 g.) formed large prisms, m. p. 74°. On being heated or on being kept in a vacuum desiccator the crystals lost one molecule of water giving a product in the form of a fine white powder, m. p. 107°, $[\alpha]_D^{20} +118^\circ$ (c, 1.0 in water) (Found: C, 50.0; H, 6.9; OMe, 23.6%).

3:4-Monoacetone 2-Methyl α -Methyl-D-galacturonoside Methyl Ester.—The above monoacetone compound (3.0 g.) was dried and methylated thrice with silver oxide and methyl iodide, giving the ester as a syrup (3.0 g.), b. p. 124° (bath temp.)/0.3 mm., n_D^{20} 1.4210 (Found: OMe, 33.5. $C_{12}H_{20}O_7$ requires OMe, 33.7%). On exposure to a moist atmosphere the syrup slowly crystallised. When recrystallised from ethyl alcohol-ligroin the monohydrate had m. p. 38°, $[\alpha]_D^{20} +116^\circ$ (c, 1.1 in water) (Found: C, 49.2; H, 7.5; OMe, 32.4. $C_{12}H_{20}O_7 \cdot H_2O$ requires C, 49.1; H, 7.6; OMe, 31.8%).

2-Methyl α -Methyl-D-galacturonoside Methyl Ester.—A sample of the above compound (0.33 g.) was hydrolysed with boiling 33% acetic acid which converted it into a syrupy mixture of 2-methyl α -methyl-D-galacturonic acid and its methyl ester (Found: OMe, 35.7. Calc. for $C_9H_{14}O_7$: OMe, 27.7. Calc. for $C_9H_{14}O_7$: OMe, 39.5%). The syrup was dissolved in methyl alcohol and esterified by the addition of excess of diazomethane. After 2 hours the solvent was removed under reduced pressure and the residual syrup distilled; b. p. 190° (bath temp.)/0.3 mm., n_D^{21} 1.4732, $[\alpha]_D^{20} +80^\circ$ (c, 1.1 in water) (Found: OMe, 37.5. $C_9H_{14}O_7$ requires OMe, 39.5%). The ester was converted in the usual way into the amide which slowly crystallised; m. p. 174°, $[\alpha]_D^{20} +55^\circ$ (c, 0.05 in alcohol) (after recrystallisation from absolute ethanol-ether) (Found: N, 6.3; OMe, 27.5. $C_9H_{14}O_6N$ requires N, 6.3; OMe, 28.1%).

Oxidation of 2-Methyl 3 : 4-Monoacetone α -Methyl-D-galacturonoside Methyl Ester.—(a) A sample of the syrupy monoacetone compound (1.3 g.) was oxidised by treating it at 100° for 35 minutes with nitric acid (*d* 1.3). There was a copious deposit of crystalline material (0.5 g.) which was difficult to recrystallise. It had m. p. 219° (decomp.) alone or in admixture with galactosaccharic acid.

From the mother liquor there was obtained a small amount of oxalic acid and a syrup (0.5 g.) which was a mixture of ill-defined products.

(b) A further carefully redistilled fraction of the monoacetone compound (0.6 g.) was hydrolysed and the products were oxidised by heating them at 80° for 15 minutes with nitric acid (*d* 1.3). On being kept overnight the solution deposited only a trace of galactosaccharic acid. The nitric acid was distilled off with water and the syrupy product converted to the methyl ester (0.8 g.) which was distilled in a high vacuum; b. p. 160–162° (bath temp.)/0.07 mm., $[\alpha]_D^{20} -19^\circ$ (*c*, 0.27 in water), yield 0.5 g. The ester was converted into an *amide* which crystallised from water in the form of long needles, m. p. 200°, and gave a positive Weerman reaction (Found: C, 38.0; H, 6.5; N, 12.3; OMe, 14.4. $C_7H_{14}O_6N_2$ requires C, 37.8; H, 6.3; N, 12.6; OMe, 14.2%).

247. *Synthesis of Some Derivatives of D- and L-Arabinose.*

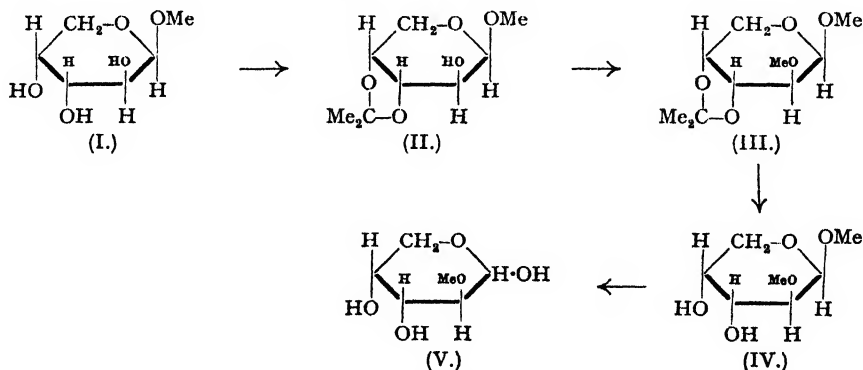

By J. K. N. JONES, P. W. KENT, and M. STACEY.

D-Arabinose has been converted into 2-methyl D-arabinose via 3 : 4-monoacetone β -methyl-D-arabopyranoside and its 2-methyl derivative. Crystalline 2-p-toluenesulphonyl 3 : 4-monoacetone β -methyl-D-arabopyranoside has also been isolated together with the crystalline p-toluenesulphonylhydrazide of 2-methyl D-arabinose. Analogous compounds, as well as the crystalline anilide of 2-methyl monoacetone L-arabinose, have been obtained from L-arabinose.

THE identification of D-arabofuranose as a constituent sugar of the polysaccharides of *M. tuberculosis* (Haworth, Stacey, and Kent, *Abs. Amer. Chem. Soc.*, Chicago Meeting, 1946, 5 R.) is of considerable interest. Although the L-isomer has been found extensively in natural polysaccharides such as the plant gums, reports of the occurrence of D-arabinose in natural compounds are comparatively rare. Its presence in barbaloin has been claimed by Leger (*Bull. Soc. chim.*, 1910, 7, 800) and it has been found in some animal secretions (Neuberg and Wohlge-muth, *Z. physiol. Chem.*, 1902, 35, 31).

The wide occurrence of L-arabinose has led to the formation and study of many of its derivatives whereas the reactions and compounds of D-arabinose are incompletely known. With a view to obtaining reference compounds and to the chemical synthesis of biologically important pentose-related substances, *e.g.*, 2-deoxyribose compounds, a number of derivatives of D-arabinose were synthesised. The present paper describes these and also some derivatives of L-arabinose required for similar purposes.

D-Arabinose obtained from calcium gluconate by essentially the method of Hockett and Hudson (*J. Amer. Chem. Soc.*, 1934, 56, 1562) was converted into crystalline β -methyl-D-arabopyranoside (I). When this compound was treated with acetone in the presence of a suitable dehydrating agent, it gave a syrupy monoacetone derivative which was shown to be 3 : 4-monoacetone β -methyl-D-arabopyranoside (II) as follows. On its being methylated with

methyl iodide and silver oxide there was formed a crystalline monomethyl monoacetone β -methyl-D-arabopyranoside (III) (m. p. 45°) which, on hydrolysis with methanolic hydrogen

chloride, afforded the 2-methyl β -methyl-D-arabopyranoside (IV) of von Schmidt and Simon (*J. pr. Chem.*, 1939, 152, 190). This compound underwent further hydrolysis with aqueous acid giving 2-methyl D-arabinose (V) which was converted into a crystalline *p*-toluenesulphonyl-hydrazone having properties identical with those of the β -methyl-D-arabinose *p*-toluenesulphonylhydrazone obtained by von Schmidt and Simon (*loc. cit.*) by the degradation of 3-methyl D-glucose.

From the monoacetone glycoside (II) there were obtained the crystalline 2-*p*-toluenesulphonyl and 2-methanesulphonyl derivatives (m. p. 134° and 135° respectively), which could not be converted directly into the 2-iodo-compound.

In the presence of acetone and excess of concentrated sulphuric acid, β -methyl-D-arabopyranoside and monoacetone β -methyl-D-arabopyranoside, lost their glycosidic groups and were converted into diacetone D-arabinose which had properties analogous to those of the diacetone L-arabinose synthesised by Svanberg and Bergman (*Chem. Zentr.*, 1924, i, 1021).

It has been reported (Ohle and Berend, *Ber.*, 1927, 60, 810) that treatment of L-arabinose with acetone in the presence of anhydrous cupric sulphate gave a monoacetone derivative which reduced Fehling's solution. An analogous *monoacetone* derivative has now been prepared from D-arabinose, and although the structure of this has not been fully investigated it is likely that the *isopropylidene* group engages the 3:4-positions. Thus on further treatment with acetone containing 2% sulphuric acid the monoacetone compound was converted into a non-reducing diacetone D-arabinose. This was identical with a diacetone D-arabinose prepared by the action of acetone containing 3% sulphuric acid upon either β -methyl-D-arabinoside or monoacetone β -methyl-D-arabopyranoside in which it is known that the acetone group engaged the 3:4-positions.

In the L-series, β -methyl-L-arabopyranoside was converted into 3:4-monoacetone β -methyl-L-arabopyranoside, from which a crystalline 2-toluenesulphonyl derivative (m. p. 134°) was obtained. Methylation of the monoacetone glycoside afforded 2-methyl 3:4-monoacetone β -methyl-L-arabopyranoside. In this compound scission of the acetone group was effected by treatment with acetic acid, and the product, 2-methyl β -methyl-L-arabopyranoside, was hydrolysed with dilute sulphuric acid giving 2-methyl L-arabinose from which a crystalline *phenylhydrazone* was isolated.

Treatment of 2-methyl L-arabinose with acetone in the presence of a dehydrating agent yielded a crystalline 2-methyl *monoacetone* L-arabinose which was reducing to Fehling's solution and, on being boiled with ethanolic aniline, gave a readily crystallised *anilide*.

EXPERIMENTAL.

D-Arabinose from Calcium D-Gluconate.—The method employed was a modification of that described by Hockett and Hudson (*J. Amer. Chem. Soc.*, 1934, 56, 1632). A solution of ferric acetate, prepared by addition of 21 g. of ferric sulphate in 60 c.c. of water to 10.5 g. of barium acetate in 60 c.c. of water, was mixed with calcium D-gluconate (200 g. in 2 l. of water), and the resulting solution heated to boiling. After filtration, the solution was warmed to 60° and 120 c.c. of 30% hydrogen peroxide in 1 l. of water were slowly added. After 2 hours, a further 120 c.c. of 30% hydrogen peroxide was added to the dark solution (at 60°). After 2 hours the solution was filtered and evaporated to 200 c.c. under diminished pressure. To the resulting syrup methanol (1600 c.c.) and ether (800 c.c.) were added. The precipitate formed was separated and the filtrate concentrated further to a thick syrup, which readily crystallised on standing at 0°. Yield of recrystallised D-arabinose, 51 g.; m. p. 155°; $[\alpha]_D^{18} - 105^\circ$ (c, 1.5 in water).

D-Arabinose (2 g.) was shaken with dry acetone (1 l.), anhydrous cupric sulphate (80 g.), and barium carbonate (10 g.) for 8 days at room temperature. The filtered solution was evaporated to dryness and the resulting syrup recrystallised from ether (0.2 g.); m. p. 78°; $[\alpha]_D^{19} - 111^\circ$ (c, 1.1 in water, no mutarotation) (cf. monoacetone L-arabinose, Ohle and Berend, *loc. cit.*; m. p. 76–77°; $[\alpha]_D + 128^\circ$). Treatment of this product with acetone and concentrated sulphuric acid yielded diacetone D-arabinose; m. p. 40–41° $[\alpha]_D^{19} - 4^\circ$ (c, 1.1 in water).

3:4-Monoacetone β -Methyl-D-arabinoside.—D-Arabinose (25 g.) was converted into the glycoside by being refluxed with methanolic hydrogen chloride (1%; 500 c.c.) for 10 hours. The β -form readily crystallised from a small amount of methanol; m. p. 168°. Yield, 12 g.

β -Methyl D-arabinose (2 g.) was shaken at room temperature with dry acetone (100 c.c.) and concentrated sulphuric acid (1.0 c.c.) for 72 hours. The acid was neutralised (litmus) by addition of anhydrous sodium carbonate. The filtered solution was evaporated to dryness, and the remaining syrup distilled in a high vacuum; b. p. 90° (vap. temp.)/0.3 mm.; n_D^{19} 1.4600 (Found: OMe, 9.2. Calc. for $C_9H_{14}O_5$: OMe, 8.9%).

β -Methyl-D-arabinoside (10 g.) or 3:4-monoacetone β -methyl-D-arabinoside (10 g.) was shaken for 24 hours with dry acetone (300 c.c.) and concentrated sulphuric acid (5 c.c.) at room temperature. After neutralisation with sodium carbonate the filtered solution was evaporated to dryness and distilled in a high vacuum. The distillate rapidly crystallised from ligroin; m. p. 41°; OMe content, nil (m. p. 41.5–43° for diacetone L-arabinose; Svanberg and Bergman, *loc. cit.*).

2-p-Toluenesulphonyl 3:4-Monoacetone β -Methyl-D-arabinoside.—3:4-Monoacetone β -methyl-D-arabinoside (0.2 g.) was dissolved in dry pyridine (7 c.c.) to which was added *p*-toluenesulphonyl chloride (0.8 g.). After 24 hours at room temperature the mixture was poured into water (200 c.c.), and the crude product which separated was recrystallised from alcohol (0.2 g.); m. p. 134° (Found: C, 53.3; H, 6.1; S, 9.3; OMe, 9.2. $C_{16}H_{18}O_7S$ requires C, 53.5; H, 6.15; S, 8.95; OMe, 8.65%).

2-Methanesulphonyl 3:4-Monoacetone β -Methyl-D-arabinoside.—3:4-Monoacetone β -methyl-D-arabinoside (0.3 g.) was dissolved in dry pyridine (10 c.c.) and treated with methanesulphonyl chloride (0.5 g.). After 48 hours the solution was poured into water (250 c.c.). No solid separated, and the aqueous solution was extracted several times with chloroform. The chloroform solution was washed with dilute hydrochloric acid and then with water and finally dried (Na_2CO_3). Evaporation of the resulting solution afforded a syrup which readily crystallised (0.2 g.) from alcohol; the compound had m. p. 135° (Found: OMe, 10.9. $C_{16}H_{18}O_7S$ requires OMe, 11.0%).

Attempted Formation of 2-Iodo 3:4-Monoacetone β -Methyl-D-arabinoside.—(i) 2-p-Toluenesulphonyl 3:4-monoacetone β -methyl-D-arabinoside (0.2 g.) was dissolved in dry acetone (20 c.c.) to which was added dry sodium iodide (2 g.). The mixture was heated at 110° for 12 hours in a sealed tube. The starting material (0.16 g.) was recovered unchanged.

(ii) 2-Methanesulphonyl 3:4-monoacetone β -methyl-D-arabinoside (0.5 g.) was heated with dry acetone (25 c.c.) and sodium iodide (2 g.) in a sealed tube at 110° or 130° for 48 hours. The starting material was recovered unchanged.

Methylation of 3:4-Monoacetone β -Methyl-D-arabopyranoside.—The monoacetone glycoside (0.7 g.) was heated for 6 hours with methyl iodide (5 c.c.) and silver oxide (1 g.). After 3 such methylations, the syrupy product was distilled; b. p. 136–137° (bath temp.)/2 mm. The distillate (n_D^{20} 1.4520) readily crystallised on standing, and after recrystallisation from acetone-ligroin the compound had m. p. 43°; $[\alpha]_D^{20} - 145^\circ$ (c. 1.8, in water) (Found: C, 55.1; H, 8.2; OMe, 28.2. $C_{16}H_{18}O_6$ requires C, 54.9; H, 8.3; OMe, 28.4%). Yield, 0.5 g.

Formation of 2-Methyl β -Methyl-D-arabopyranoside.—2-Methyl 3:4-monoacetone β -methyl-D-arabopyranoside (0.3 g.) was heated for 3 hours with methanolic hydrogen chloride (20 c.c.; 5%); $[\alpha]_D^{20} - 130^\circ \rightarrow -35^\circ$. The resulting solution was neutralised (litmus) with silver carbonate and the filtrate evaporated, giving a syrup, n_D^{20} 1.4602, which crystallised on standing (0.2 g.). After recrystallisation from methanol-ether the compound had m. p. 48° (Found: OMe, 31.6. $C_7H_{14}O_6 \cdot H_2O$ requires OMe, 31.6%).

2-Methyl D-Arabinose.—2-Methyl β -methyl-D-arabopyranoside (0.2 g.) was heated at 100° for 6 hours with sulphuric acid (N; 10 c.c.); $[\alpha]_D^{20} - 96^\circ \rightarrow -56^\circ$. The solution reduced Fehling's solution and was neutralised (phenolphthalein) with sodium hydroxide and evaporated, and the residue extracted with chloroform. On evaporation of the chloroform extract to dryness, 2-methyl D-arabinose was obtained as a reducing syrup (0.1 g.); n_D^{20} 1.4710 (Found: OMe, 18.6. $C_6H_{12}O_5$ requires OMe, 18.9%).

Treatment of this syrup with phenylhydrazine (3 drops), glacial acetic acid (4 drops), and water (2 c.c.) at room temperature for several hours afforded a crystalline phenylhydrazone which, after recrystallisation from aqueous ethanol, had m. p. 113° (Found: OMe, 12.2. $C_{12}H_{18}O_4N_2$ requires OMe, 12.2%).

Formation of 2-Methyl D-Arabinose p-Toluenesulphonylhydrazone.—2-Methyl D-arabinose (0.1 g.) was dissolved in absolute alcohol (8 c.c.), treated with *p*-toluenesulphonylhydrazine (Freudenberg and Blümmel, *Annalen*, 1924, 440, 51) (0.1 g.), and the mixture heated under reflux for 1 hour. On removal of the solvent, the *p*-toluenesulphonylhydrazone separated, and after recrystallisation from aqueous alcohol had m. p. 143° (decomp.); $[\alpha]_D^{16} - 17.0^\circ$ (c. 0.8 in water) (initial value) (Found: OMe, 9.1. $C_{13}H_{20}O_6N_2S$ requires OMe, 9.4%).

3:4-Monoacetone β -Methyl-L-arabinoside.—(a) β -Methyl-L-arabopyranoside (2 g.) was shaken with acetone (250 c.c.) and anhydrous copper sulphate (10 g.) for 7 days. The solution was then filtered and the filtrate concentrated under diminished pressure to a syrup (2 g.), n_D^{20} 1.4642.

(b) (Cf. Robertson and Speedie, *J.*, 1934, 824.) The arabinoside (2 g.) was shaken with acetone (20 c.c.) containing hydrogen chloride (2 g.) for 48 hours. The clear solution was then poured into excess of dilute sodium hydroxide solution and the product extracted thrice with chloroform. The chloroform solution was then dried (Na_2CO_3), filtered, and concentrated under reduced pressure to a syrup (1.8 g.) which was distilled; the compound had b. p. 105° (bath temp.)/0.01 mm.; n_D^{20} 1.4628 (Found: C, 52.9; H, 8.1. $C_6H_{12}O_5$ requires C, 52.9; H, 7.9%).

The corresponding 2-p-toluenesulphonyl derivative was prepared by reaction of 3:4-monoacetone β -methyl-L-arabinoside (4.0 g.) with *p*-toluenesulphonyl chloride (4.5 g.; 1.1 ml.) in dry pyridine (25 c.c.) at 40°. The warm solution was diluted with water and cooled, and the product filtered off and dried. Yield, 4.5 g.; m. p. 134° (Found: C, 53.8; H, 5.6; OMe, 8.6. $C_{16}H_{18}O_7S$ requires C, 53.6; H, 6.2; OMe, 8.7%). Hydrolysis of this product with boiling 50% acetic acid gave 2-p-toluenesulphonyl β -methyl-L-arabinoside in low yield as deliquescent crystals of low melting point. The product was not further examined.

2-Methyl 3:4-Monoacetone β -Methyl-L-arabopyranoside.—3:4-Monoacetone β -methyl-L-arabopyranoside (2 g.) was methylated with silver oxide and methyl iodide and the product distilled under reduced pressure. The corresponding 2-methyl ether distilled at 100° (bath temp.)/0.01 mm.; n_D^{20} 1.4481 (Found: C, 54.9; H, 8.3; OMe, 28.4. $C_{10}H_{18}O_6$ requires C, 55.1; H, 8.2; OMe, 28.4%).

2-Methyl β -Methyl-L-arabopyranoside.—2-Methyl 3:4-monoacetone β -methyl-L-arabopyranoside (1.86 g.) was boiled with water (20 c.c.) containing glacial acetic acid (5 c.c.) for 2 hours ($[\alpha]_D^{20} + 202^\circ$ initial value, $\rightarrow +186^\circ$). The solution was concentrated under reduced pressure to a syrup which was distilled in a vacuum; b. p. 130° (bath temp.)/0.01 mm.; n_D^{20} 1.4768. This product crystallised shortly after distillation; m. p. 59° (Found: C, 47.0; H, 8.2; OMe, 34.2. $C_7H_{14}O_6$ requires C, 47.2; H, 7.9; OMe, 34.8%). On recrystallisation from acetone-ether the arabinoside separated as the monohydrate, m. p. 47° (Found: C, 42.9; H, 7.7; OMe, 31.4. $C_7H_{14}O_6 \cdot H_2O$ requires C, 42.9; H, 8.2; OMe, 31.6%).

2-Methyl L-Arabinose.— β -Methyl 2-methyl-L-arabinoside (1.06 g.) was hydrolysed with boiling N-sulphuric acid (25 c.c.) for 4 hours; $[\alpha]_D^{20} + 234^\circ$ (initial value) $\rightarrow +99^\circ$ (constant value). The

cooled solution was neutralised with barium carbonate and filtered, and the filtrate evaporated under reduced pressure to a syrup which did not crystallise. With alcoholic phenylhydrazine crystalline 2-methyl L-arabinose phenylhydrazone was obtained, m. p. 116° after recrystallisation from alcohol-ether-light petroleum (Found : C, 56.8; H, 7.8; N, 10.9; OMe, 12.4. $C_{12}H_{18}O_4N_2$ requires C, 56.7; H, 7.1; N, 11.0; OMe, 12.2%). No crystalline anilide could be isolated.

On shaking an acetone solution with anhydrous copper sulphate 2-methyl L-arabinose gave 2-methyl monoacetone L-arabinose which, on evaporation of the filtered solution, was isolated as a crystalline reducing solid, m. p. 117°. It was purified by recrystallisation from acetone and sublimed in a vacuum (Found : C, 52.8; H, 7.8; OMe, 15.1. $C_8H_{14}O_5$ requires C, 52.9; H, 7.8; OMe, 15.2%).

On being heated with alcoholic aniline this product gave crystalline 2-methyl monoacetone L-arabinose anilide, m. p. 143° after recrystallisation from ethyl alcohol (Found : C, 64.4; H, 7.4; N, 4.8; OMe, 11.0. $C_{15}H_{21}O_4N$ requires C, 64.6; H, 7.4; N, 5.0; OMe, 11.1%).

248. The Quantitative Separation of Methylated Sugars.

By F. BROWN and J. K. N. JONES.

Two methods for the quantitative separation of fully methylated sugars from their partly methylated derivatives are described. The first is a standardised procedure for the quantitative chromatographic separation of methylated sugar glycosides on activated alumina by means of which quantities as small as 245 mg. of tetramethyl methylglucoside can be separated from a large excess of 2:3:6-trimethyl methyl- α -glucoside. In the second method the fully methylated sugar glycoside, which may weigh as little as 36 mg., can be recovered from admixture with a large excess of admixed partly methylated sugar glycosides by preferential extraction of the fully methylated derivative with light petroleum from water using two continuous extraction apparatuses, one fitted above the other.

DETAILED knowledge of structure in the carbohydrate group has been largely dependent upon the possibility of separating and identifying the various components of the mixture of methylated sugars obtained on hydrolysis of the methyl ethers of the materials under investigation. The quantitative aspect of this problem assumed special importance in the development of the chemical end group method applied by Haworth and Machemer (*J.*, 1932, 2270) in their determination of the chain length of cellulose. This involved the quantitative separation, by fractional distillation, of a very small amount of tetramethyl glucose from a larger amount of 2:3:6-trimethyl glucose, similar problems being met with in studies on starch and glycogen. Even in this comparatively simple case complications are encountered in the course of the fractional distillation of the mixture of methylated methylglucosides, and special methods had to be adopted in order to obtain accurate results (see Hirst and Young, *J.*, 1938, 1247; Averill and Peat, *ibid.*, p. 1244; Peat and Whetstone, *J.*, 1940, 276). In the course of attempts to overcome the difficulties inherent in the method of separation by distillation other procedures have been elaborated, including, for example, (a) phosphorylation of the partly methylated glycosides followed by extraction of the fully methylated glycoside from aqueous solution by organic solvents (Hess and Neumann, *Ber.*, 1937, 70, 710; Leckzyk, *ibid.*, 1938, 71, 829; Hess, Grigorescu, Steurer, and Forham, *Ber.*, 1940, 73, 505), and (b) separation of the sugars on silica (Bell, *J.*, 1944, 473), or chromatographic separation of the glycosides on alumina (Jones, *J.*, 1944, 333).

An outline of the method of separation of methylated sugar glycosides on alumina has already been given (Jones, *loc. cit.*). We have now standardised this method and find it so sensitive that even the α - and β -methylglucosides of tetramethyl glucopyranose may be separated partially one from another. The recovery of the sugars by this procedure amounts to 93% of the fully methylated sugar, so that a small correction is necessary in order to obtain the exact amount of end-group present.

A further method, which we have developed quantitatively on the semi-micro scale, depends upon the fact that fully methylated sugars are much more readily extracted from water with light petroleum (b. p. 38–40°) than are partly methylated sugars. Tetramethyl methylglucoside has a partition coefficient of about 10 between chloroform and water whilst the partition coefficient found for 2:3:6-trimethyl methylglucoside is about 2 between chloroform and water (cf. the work of Macdonald, *J. Amer. Chem. Soc.*, 1935, 57, 771, who determined the coefficient for the corresponding free sugars). We have found that the partition coefficient of fully methylated glucose between light petroleum (b. p. 38–40°) and water is about 0.1 whilst the correspond-

ing figure for trimethyl methylglucoside is <0.01 . The ratio between these last two figures is such that we were able to develop a method for the separation of the sugar derivatives by a continuous extraction process.

In carrying out the separation two continuous extractors are fitted, one above the other. In the top apparatus is placed the mixture of glycosides dissolved in water or sodium hydroxide solution, whilst the bottom apparatus initially contains water only. The apparatus is connected to a reservoir flask containing boiling light petroleum (b. p. 38–40°). The vapours are condensed and drop through the top solution and extract a mixture of sugars, mainly the fully methylated α - and β -glycosides; the extracts are then washed by passing through the water in the lower apparatus and finally return to the reservoir. This extraction is interrupted at intervals, solvent evaporated, the residual syrup weighed, and the refractive index determined. When a refractive index, combined with optical rotatory determination, shows the extract to be free from the fully methylated derivative (Hirst and Young, *loc. cit.*), the previous extracts are combined and dissolved in water, and the whole process is repeated in a similar apparatus. Eventually, following this technique, fractions consisting of fully methylated glycosides free from partly methylated sugars are obtained. In trial experiments the recovery of fully methylated sugar glycosides was of the order of 98–102%. By the use of this method the quantitative separation of the methylglucosides of 2:3:4:6-tetramethyl *d*-glucose and 2:3:6-trimethyl *d*-glucose (1:1 mixtures), and of 2:3:4:6-tetramethyl *d*-galactose and 2:3:6-trimethyl *d*-glucose (1:1 mixtures) has been achieved. This method has also been applied successfully to the quantitative separation of one part of tetramethyl methylglucoside (36 mg.) from 24 parts of partly methylated methylglucosides (865 mg.), and can be used with reasonable accuracy for still lower concentrations of the fully methylated sugar. These methods can therefore be applied to the determination of the size of the repeating unit of methylated polysaccharides. Since the partition method is applicable also to the quantitative separation of fully methylated pentose sugars from partially methylated pentose and hexose sugars, it can be used for the quantitative determination of the sugars formed on methanolysis of the complex methyl ethers of gums and mucilages; as an example of its utility the quantitative separation of the methylglycosides produced on hydrolysis of methylated peanut araban is described. The results obtained are in full agreement with those obtained by using the distillation procedure (Hirst and Jones, in the press).

Experimental difficulties may arise if the methylated polysaccharide is not rigorously purified before methanolysis, since any impurities present in it which are soluble in light petroleum will contaminate the fully methylated sugar finally obtained. In the event of a coloured and impure fraction of fully methylated sugar being isolated it may be purified by distillation in an apparatus of the type described by Ellis (*Chem. and Ind.*, 1934, 77). The loss during the final distillation is less than 1 mg. on quantities of the order of 40 to 100 mg. of tetramethyl methyl-*d*-glucoside.

EXPERIMENTAL.

As a result of many experiments with various solvents and weights of alumina the following technique was found to be the most satisfactory for the separation of tetramethyl α - and β -methyl-*d*-glucoside from a mixture of 2:3:4:6-tetramethyl methyl-*d*-glucoside and 2:3:6-trimethyl methyl-*d*-glucoside.

A solution of 2:3:4:6-tetramethyl α -methyl- (530 mg.) and β -methyl- (515 mg.) *d*-glucoside and 2:3:6-trimethyl methyl-*d*-glucoside (1.02 g., prepared from pure 2:3:6-trimethyl *d*-glucose) in light petroleum (b. p. 60–80°; washed with sulphuric acid and sodium hydroxide solution and distilled) was passed through a column of alumina (from the British Aluminium Co., Burntisland, Scotland, activated at 360° for 4 hours; 350 g., length 18 ins., cross section $1\frac{1}{4}$ ins.), and the column developed with chloroform [dried (CaCl₂) and distilled]. The eluate was collected in fractions (100 c.c.) each of which was tested for the presence of sugars by the Molisch test after withdrawing a sample (5 c.c.) and removing the solvent by evaporation. After the passage of chloroform (1100 c.c.), fractions of sugar were isolated having the following properties, all rotations being measured in chloroform solution: (1) 50 mg., n_D^{18} 1.4440, $[\alpha]_D^{18}$ +75°; (2) 60 mg., n_D^{18} 1.4436, $[\alpha]_D^{18}$ +110°; (3) 125 mg., n_D^{18} 1.4442, $[\alpha]_D^{18}$ +130°; (4) 90 mg., n_D^{18} 1.4437, $[\alpha]_D^{18}$ +83°; (5) 70 mg., n_D^{18} 1.4436, $[\alpha]_D^{18}$ +68°; (6) 105 mg., n_D^{18} 1.4420, $[\alpha]_D^{18}$ +20°; (7) 440 mg., n_D^{18} 1.4414 (superfused), $[\alpha]_D^{18}$ –25°. The syrup from this fraction crystallised; m. p. 37°. Total yield, 940 mg. (92% recovery). The next fractions gave a weak positive Molisch test but left no weighable residue of sugar on evaporation. The trimethyl methyl-*d*-glucoside was eluted with methyl alcohol. Yield, 1.0 g. Since the yield of fully methylated sugar which would be isolated from a partly methylated starch of weight 5 g. (an amount convenient to handle in methylation work) is about 240 mg., tetramethyl methylglucoside (245 mg., n_D^{18} 1.4440) and trimethyl methylglucoside (382 mg., n_D^{18} 1.4572) were separated. The sugars, dissolved in light petroleum (b. p. 40–60°, 50 c.c.), were passed through a column of activated alumina (18 ins. \times $1\frac{1}{4}$ ins.). The alumina was then eluted with alcohol-free, dry chloroform and the following fractions of sugars isolated on concentration of 100 c.c. portions of the chloroform eluate: Fraction A (28 mg.), n_D^{18} 1.4462; Fraction B (49 mg.), n_D^{18} 1.4460; Fraction C (51 mg.), n_D^{18} 1.4449; Fraction D (24 mg.), n_D^{18} 1.4440; Fraction E (54 mg.), n_D^{18} 1.4420; Fraction F (20 mg.), n_D^{18} 1.4415. This last fraction crystallised; m. p. of solid, 37°. Two further

fractions contained a negligible amount of sugar (<1 mg.)—thereafter trimethyl methylglucoside was eluted. This yield of sugars (Fractions A to F, 226 mg.) corresponds to a yield of 93%.

Since the yield of 2 : 3 : 4 : 6-tetramethyl methyl-*d*-glucoside was 92%, a correction is necessary when applying this method to the determination of the repeating unit of methylated starch or glycogen. The technique described above is applied to the separation of approximately equal parts of tetramethyl and trimethyl methyl-*d*-glucosides. To approximate to these conditions when carrying out a determination of the repeating unit of a polysaccharide it is necessary to carry out a preliminary enrichment of the "tetra" fraction present in the hydrolysis products from the methylated polysaccharides. This is carried out by the following general procedure. The methylated polysaccharide is hydrolysed by boiling with methanolic hydrogen chloride. After neutralisation of the solution, with silver carbonate, *N*-sodium hydroxide (slight excess), or diazomethane, and filtration if necessary, solvent is removed at 760 mm. on the water-bath and finally in a vacuum at 25°, and the residual syrup dissolved in water (ca. 50 c.c.) and extracted continuously with redistilled sulphur-free light petroleum in an all-glass apparatus for about 4 hours. This procedure usually removes all the fully methylated sugar from the aqueous solvents along with about an equal weight of trimethyl methylglucoside. To guard against incomplete extraction, the water solution is again extracted with light petroleum (b. p. 38–40°) for about 4 hours, and the extracts are added to the first extract. If the sodium hydroxide neutralisation technique is used, contamination of the fraction rich in fully methylated sugar with methyl lavulate is avoided. These extracts are then combined and concentrated, and the product is weighed and subsequently separated on the column as described above.

Quantitative Separation of Fully Methylated Sugars from Partly Methylated Sugars by Partition between Water and Light Petroleum (b. p. 38–40°).—The mixture of methylated methylglucosides is dissolved in dilute sodium hydroxide solution (to remove traces of acids and esters) and extracted continuously in an apparatus consisting of two all-glass continuous extraction vessels ("Quickfit" and Quartz/EX8/23) in series. The solution of sugars (40 c.c.) is placed in the top apparatus; the second extractor contains water (75 c.c.) which serves the purpose of washing the light petroleum extracts.

In a trial experiment fully methylated glucose ($n_D^{18} 1.4434$; 257 mg.) and trimethyl methylglucoside ($n_D^{18} 1.4572$; 223 mg.) were dissolved in water (40 c.c.) and extracted in the apparatus for 2½ hours. Concentration of the extract gave a syrup (235 mg.; $n_D^{18} 1.4434$; $[\alpha]_D^{20} +53^\circ$, in water). Further extraction for two hours gave a syrup (20 mg.; $n_D^{18} 1.4430$; $[\alpha]_D^{20} +40^\circ$, in water). Two further extracts of 2 hours each gave products (9 mg. and 12 mg.) which were trimethyl methylglucoside. Recovery is therefore 255 mg. or 99%.

In a second experiment tetramethyl methylglucoside (126 mg.; $n_D^{18} 1.4437$) and trimethyl methylglucoside (129 mg.; $n_D^{18} 1.4572$) were dissolved in water (50 c.c.) and extracted as before for 2½ hours. Concentration of the extract left a residual syrup (107 mg.; $n_D^{18} 1.4431$; $[\alpha]_D^{20} +38^\circ$). Further extraction for 2 hours gave a syrup (23 mg.; $n_D^{18} 1.4423$; $[\alpha]_D^{20} +14^\circ$). Continuation of the extraction (2 periods of 2 hours) gave on concentration a very small yield of syrup (1–2 mg.). Recovery of fully methylated glucose, 102%.

In the above two experiments the ratio of tetramethyl to trimethyl methylglucoside is about 1 : 1. With most polysaccharides, e.g., starches and celluloses, the proportion of end group is much less than this, and further experiments were carried out to test the accuracy of this method when applied to mixtures containing one part of tetramethyl methylglucoside to 19–34 parts of trimethyl methylglucoside. Fully methylated glucose (140 mg.; $n_D^{18} 1.4438$) and trimethyl methylglucoside (2577 mg.; $n_D^{18} 1.4574$) were dissolved in water (50 c.c.) and extracted for 5 hours. Concentration of the extract left a syrup (C) (347 mg.; $n_D^{18} 1.4510$). Further extraction with light petroleum gave a syrup (93 mg.; $n_D^{18} 1.4550$) which contained no fully methylated glucose since on extraction in the same way for 5 hours it yielded trimethyl *d*-methylglucoside (7 mg.) only. Accordingly the extract (C) (347 mg.) was dissolved in water (50 c.c.) and extracted once again for 5 hours. Yield of syrup, 138 mg.; $n_D^{18} 1.4434$; $[\alpha]_D^{20} +60^\circ$ (in water). Further extraction for two hours gave the partly methylated glucose (16 mg.), $n_D^{18} 1.4562$. Recovery of fully methylated glucose is therefore 138 mg. (98.5%).

In another experiment a mixture of tetramethyl (53 mg.; $n_D^{18} 1.4438$) and 2 : 3 : 6-trimethyl methyl-*d*-glucoside (1715 mg.; $n_D^{18} 1.4574$) and 2 : 3-dimethyl methylglucoside (157 mg.; m. p. 79°) were put through this double procedure which resulted in a recovery of 98% of the fully methylated sugar (52 mg.; $n_D^{18} 1.4441$; $[\alpha]_D^{20} +80^\circ$).

In a further experiment a mixture of tetramethyl methylglucoside (36 mg.; $n_D^{18} 1.4440$), 2 : 3 : 6-trimethyl methylglucoside (865 mg.; $n_D^{18} 1.4582$), and 2 : 3-dimethyl methylglucoside (26 mg.; m. p. 79°) was extracted in the same way and gave a recovery of the fully methylated sugar of 100% (36 mg.; $n_D^{18} 1.4441$; $[\alpha]_D^{20} +80^\circ$ in water).

Separation of Tetramethyl Methylgalactoside and 2 : 3 : 6-Trimethyl Methylglucoside.—Heptamethyl methyl-lactoside (199 mg.; m. p. 77–79°) was dissolved in boiling methanolic hydrogen chloride (25 c.c.; 1%) and hydrolysed by boiling the solution for 8 hours. The solution was then neutralised with *N*-sodium hydroxide and concentrated in a vacuum to a syrup which was dissolved in water (50 c.c.) and extracted continuously with light petroleum (b. p. 38–40°) in the standard apparatus. Continuous extraction of the aqueous solution for 9 hours gave tetramethyl methylgalactoside [105 mg. (96%); $n_D^{18} 1.4492$] on concentration of the extracts. Further extraction for 3 hours gave, on removal of the solvent, < 3 mg. of syrup. The syrup (105 mg.) was hydrolysed with boiling *N*-hydrochloric acid, and the syrupy 2 : 3 : 4 : 6-tetramethyl *d*-galactose isolated in the usual manner and identified by conversion into the corresponding crystalline anilide, m. p. and mixed m. p. with an authentic specimen, 190°. The aqueous solutions remaining in the apparatus were then combined and extracted continuously with chloroform. Removal of the solvent left 2 : 3 : 6-trimethyl methylglucoside [102 mg. (98%); $n_D^{18} 1.4574$], identified after hydrolysis with boiling *N*-hydrochloric acid as 2 : 3 : 6-trimethyl *d*-glucose.

Separation of the Hydrolysis Products of Methylated Peanut Arabin.—(a) Methylated peanut arabin (4.4 g.) was boiled with methanolic hydrogen chloride (1%; 100 c.c.) during 7 hours. The cooled solution was neutralised with silver carbonate and filtered. The filtrate on concentration gave a mixture of glycosides (5.2 g.) which was fractionated. A portion of this syrupy product (1.519 g.) was dissolved in water

(50 c.c.) and extracted continuously in a double extractor with purified light petroleum (b. p. 38–40°). The following fractions were obtained: Fraction 1 (0.498 g.), n_D^{20} 1.4380; Fraction 2 (0.039 g.), n_D^{20} 1.4439; Fraction 3 (0.53 g.), n_D^{20} 1.4510. Fractions 1 and 2 contained 0.517 g. of trimethyl methyl-*l*-arabinoside corresponding to a yield of 32% (calculated on the weight of glycosides) (Found by the distillation method: 32.2%).

(b) A further portion of the methanolysis product (1.31 g.) of methylated peanut araban was dissolved in water (50 c.c.) and extracted continuously in a double extractor as described above. The following fractions were isolated: 2:3:5-Trimethyl methyl-*l*-arabinoside (0.42 g.), n_D^{18} 1.4390 (Found: OMe, 59.7. Calc. for $C_6H_{14}O_5$: OMe, 60.2%); 2:3-dimethyl methyl-*l*-arabinoside (0.40 g.), n_D^{18} 1.4530 (Found: OMe, 48.2. Calc. for $C_6H_{14}O_5$: OMe, 48.4%). The residual aqueous solution on concentration gave 2-methyl methyl-*l*-arabinoside (0.46 g.), n_D^{18} 1.4749 (Found: OMe, 37.2. Calc. for $C_7H_{14}O_5$: OMe, 34.8%). Total recovery of sugars, 98%. These figures indicate that trimethyl, dimethyl, and monomethyl methyl-*l*-arabinoside were present after methanolysis in equimolecular proportions.

The authors thank Professor E. L. Hirst, F.R.S., for his interest and advice and the British Cotton Industry Research Association for the award of a Shirley Fellowship to one of them (F. B.).

THE UNIVERSITY OF MANCHESTER.

[Received, December 13th, 1946.]

249. Qualitative Semimicro-analysis with Reference to Noyes and Bray's System: Partial Analysis of the Combined Nickel, Zirconium, and Rare-earth Groups.

By CHRISTINA C. MILLER.

A scheme of analysis is presented for the detection and approximate determination of 0.25–50 mg. of manganese, cobalt, or nickel, 0.25–10 mg. of titanium, zirconium, indium, or scandium, and a small amount of zinc (minimum 0.25 mg.) in solutions containing a maximum of 50 mg. referred to the metals. These include all the more important elements present in the combined nickel, zirconium, and rare-earth groups of Noyes and Bray's scheme. The maximum amount of any one rare-earth group metal is 10 mg. In separate portions of the solution, manganese, cobalt, nickel, titanium, and zirconium are detected, respectively, by means of potassium periodate, ammonium thiocyanate and extraction with butyl acetate, dimethylglyoxime, chromotropic acid, and *p*-hydroxyphenylarsonic acid. In a sixth portion zinc is separated from cobalt and more than 1 mg. of nickel, and tested for with copper sulphate and ammonium mercury thiocyanate. Finally, in a seventh portion indium and scandium are isolated. Indium is precipitated as indium sulphide and confirmed with alizarin, and scandium detected by means of alizarin-S or morin.

SCHEMES for the analysis on a semimicro-scale of seven groups of Noyes and Bray's system ("A System of Qualitative Analysis for the Rare Elements," 1927) have already been reported by Miller and Lowe (*J.*, 1940, 1258, 1263) and Miller (*J.*, 1941, 72, 786; 1943, 72). This paper describes the further application of semimicro-analytical methods to the detection of manganese, cobalt, nickel, zinc, titanium, zirconium, indium, and scandium in a group containing all the more important metals associated with the nickel, zirconium, and rare-earth groups of Noyes and Bray's scheme.

After removing metals precipitable by hydrogen sulphide in acid solution, Noyes and Bray precipitate those of the ammonium sulphide group in two separate operations. From one precipitate iron, gallium, and components of the aluminium group are eliminated, leaving indium, zirconium, and titanium (zirconium group), some rare-earth group metals, and traces of cobalt, nickel, and zinc. From the other precipitate components of the aluminium group are removed, leaving manganese, cobalt, nickel, and a little zinc (nickel group), and some rare-earth group metals. In the course of analysis of the second precipitate the rare-earth group portion is separated and added to the first precipitate, from which the whole rare-earth group (scandium, thorium, yttrium, lanthanum, cerium, etc.) is extracted before the zirconium group proper is analysed. A variable amount of indium is located in the rare-earth group so that the metal has to be tested for twice.

The method of analysis used here is entirely different. It is supposed that the above precipitates are dissolved in hydrochloric acid and the solutions combined to give a mixture inclusive of all the components of Noyes and Bray's three groups. The mixtures considered here may contain any of *e.g.*, manganese, cobalt, nickel, titanium, zirconium, zinc, indium, scandium, thorium, yttrium, cerium, lanthanum, neodymium, and praseodymium. In portions of them the first five, and sometimes zinc, are tested for directly. Indium and scandium, and zinc in certain circumstances, are detected after they have been freed from interfering elements. In this connection organic solvents as extractants play an important part. As

in earlier papers the experimental conditions described permit the detection of the above metals in accordance with the limits set forth in the summary. Provision is made for the presence of group contaminants, *e.g.*, iron, gallium, and members of the aluminium group. Because of scarcity of material the question of the detection of hafnium, which behaves like zirconium, has not yet been considered, and other rare-earth metals have not been taken into account.

Particulars regarding the isolation of the rare-earth group of metals from one half of the above mixtures, and the subsequent analysis of the group, will, it is hoped, be given later.

EXPERIMENTAL.

Preparation of the Group for Analysis.—Mixtures containing chlorides or nitrates of the various metals and some hydrochloric acid were evaporated just to dryness and taken up in 1 ml. of 6*N*-hydrochloric acid.

Nickel, Zirconium, and Rare-earth Groups.

(The figures in parentheses are referred to in "Notes on Methods and Tests.")

Solution.—Contains cobalt, manganese, nickel, titanium, zirconium, zinc, indium, scandium, thorium, yttrium, lanthanum, cerium, neodymium, and praseodymium as chlorides in 1 ml. of 6*N* hydrochloric acid. Test separate portions as follows:

(a) Test 1% for Co in a test-tube ($\frac{3}{8}$ " \times 3"). Make 0.15 ml. of solution, 2*N* in HCl, add 10–20 mg. of NH_4F and NH_4SCN in large excess. Add 0.2 ml. of *n*-butyl acetate and shake briskly. A blue colour in the ester shows **Co**. Increase the ester to a maximum of 2 ml. when much Co is present. Compare with standards. (1.)

(b) Test 1% for Mn in a 5-ml. beaker. Add 0.05 ml. of H_3PO_4 (88%) and expel HCl by evaporating on the hot-plate. Then add 1 ml. of 2*N*- HNO_3 and 10 mg. of KIO_4 , and keep the solution at the boiling point in the covered beaker for at least 15 mins., keeping the volume constant by additions of water. A purple colour shows **Mn**. Centrifuge if necessary and compare with standards. (2.)

(c) Test 1% for Ni in a 0.5-ml. centrifuge tube. Add 0.1 ml. of 12% aqueous citric acid and 0.05 ml. of ammonia (*d* 0.88). Heat to 80°, add 0.05 ml. of 5% aqueous dimethylglyoxime (Na salt)—allow more for Co (0.1 ml. per 0.5 mg.)—stir thoroughly, and heat further for 1 min. If a red precipitate due to **Ni** appears, ensure complete precipitation, then centrifuge without cooling, separate the precipitate, dissolve it in 2*N*-HCl, and reprecipitate as before. Compare with standards. (3.)

(d) Test 0.25–1% for Ti on a spotting tile. Add 0.04 ml. of 0.2*M*- SnCl_2 in *N*-HCl and 0.05 ml. of 1% chromotropic acid in concentrated H_2SO_4 . Compare a violet colour, which shows **Ti**, with standards. (4.)

(e) Test 5% for Zr in a 1-ml. centrifuge tube. Make 0.25 ml. of solution, 4*N* in HCl, add 0.05 ml. of perhydrol if Ti is present, heat, and add 0.1 ml. of 4% aqueous *p*-hydroxyphenylarsonic acid. Heat in boiling water for 2 mins. and centrifuge. If a precipitate is present, separate it and add 0.05 ml. of perhydrol and 0.1 ml. of 2*N*-NaOH. Stir up, centrifuge, separate $\text{Zr}(\text{OH})_4$, and dissolve it in 0.1 ml. of 10*N*-HCl and 0.1 ml. of water. Treat with *p*-hydroxyphenylarsonic acid as before. A white precipitate shows **Zr**. Centrifuge and compare with standards. (5.)

(f) Test 10% for Zn. (i) Co absent, Ni < 100 μg . Make 0.25 ml., *N* in HCl, in a 0.5-ml. centrifuge tube, add 0.01 ml. of 0.01*M*- CuSO_4 and 0.1 ml. of ammonium mercury thiocyanate reagent (30 g. of HgCl_2 and 33 g. of NH_4SCN in 100 ml. of water). Stir briskly and centrifuge. A black or violet precipitate shows **Zn** which should be compared with standards. (6.)

(ii) Ni > 100 μg ., and/or Co present. Make 0.5 ml., 2*N* in HCl, in a "Pyrex" test-tube ($\frac{3}{8}$ " \times 3"), add a large excess of NH_4SCN and 100 mg. of NH_4F , and extract twice with 1 ml. of *n*-butyl acetate. Evaporate the combined extracts, with the aid of an air current, in a "Pyrex" test-tube placed in boiling water. Next cautiously decompose the thiocyanates with concentrated HNO_3 , and finally heat in a flame (air current still flowing) until all volatile products are expelled.

If Co is absent, dissolve the residue in 0.25 ml. of *N*- HNO_3 and test for Zn as in (i). If < 500 μg . of Co is present, add 0.2 ml. of water, 0.2 ml. of 2*N*-NaOH, and a drop of 3% H_2O_2 , boil, centrifuge, remove the solution, and add to it 0.04 ml. of concentrated HNO_3 . Test for Zn as in (i).

If > 500 μg . of Co is present, add to the residue 0.1 ml. of water and just enough 10% aqueous KCN to convert Co into a soluble complex. Add 1 drop of perhydrol and boil for a few mins. to form cobalticyanide. Then add glacial acetic acid in 20% excess by volume, and 0.05 ml. of 10% aqueous potassium cobalticyanide, and heat. If a turbidity appears heat further to coagulate. Separate and wash the precipitate, which may be zinc cobalticyanide, without stirring it up, in 2*N*-acetic acid. To confirm Zn add to the precipitate 0.05 ml. of 4*N*- H_2SO_4 , heat until fumes of H_2SO_4 appear and the precipitate is dissolved, and proceed with the removal of Co and the final test for Zn as above. (7.)

(g) Test 10% for In and Sc in a test-tube ($\frac{3}{8}$ " \times 3"). Add 0.05 ml. of 10*N*-HCl, 0.05 ml. of water, and 0.3 ml. of 10% aqueous cupferron. Extract thrice with 1 ml. of chloroform. To the residual aqueous layer add a large excess of NH_4SCN and extract twice with 1 ml. of *n*-butyl acetate. Wash the combined extracts with 0.05 ml. of 2*N*-HCl, saturated with NH_4SCN . Expel the ester, destroy thiocyanates, and remove volatile products as described under (f, ii). Dissolve the residue in 0.15 ml. of water, make approximately neutral, and add sufficient 10% aqueous KCN to convert Co and Zn into soluble complexes. Add a drop of perhydrol, boil, add a few drops of 2*N*-NaOH, and reboil for a short time. If a precipitate [$\text{In}(\text{OH})_3$ and $\text{Sc}(\text{OH})_3$] appears, separate it, wash it with hot water, and dissolve it in 0.5 ml. of 2*N*-acetic acid. (8.)

(i) Test for In. Into the hot solution pass H_2S for 10 mins. A yellow precipitate shows **In**. Centrifuge and determine it. If desired, confirm a small precipitate, after washing it, with alizarin. (9.)

(ii) Test for Sc in the centrifugate from In_2S_3 . H_2S must be absent for test (9).

(a) To 0.25 ml. of 2*N*-acetic acid add 0.01 ml. of 1% aqueous alizarin-S and 0.05 ml. of the test

solution, and set aside for 5 mins. If no pink colour is, observed add more test solution gradually up to a maximum of 0.25 ml., and more reagent if necessary. If a pink colour due to **Sc** appears readily, add additional reagent gradually. Should the colour become too deep a red, repeat the experiment with less of the test solution. Compare with standards. Allow 20 mins. for full colour development. (10.)

(β) To 0.25 ml. of 2*N*-acetic acid add 0.01 ml. of morin (0.02% in acetone) with which **Sc** shows a green fluorescence in ultra-violet light. Gradually add the test solution, up to a maximum of 0.25 ml. if necessary, until a match is obtained with a standard containing between 1 and 50 μg. of **Sc**. (11.)

(h) Reserve 50% for the isolation of the rare-earth group.

Notes on Methods and Tests.—The experimental technique has been described in earlier papers of the series.

Note 1. The amount of ammonium thiocyanate was such that some remained undissolved throughout the extraction process. The ammonium fluoride masked titanium (0.5 mg.) and group contaminants, *e.g.*, iron, vanadium, and uranium. 0.5 μg. of cobalt was detectable in 0.2 ml. of ester. The extraction of cobalt was highly efficient, and 2 ml. of ester were used merely when the colour was otherwise too dark for matching purposes. The detection of 1 μg. of cobalt was not affected by the presence of at least 1 mg. of any of its associates, or of any member of the aluminium group (Al, Be, Cr^{VI}, W^{VI}, U^{VI}, V^V), or of iron or gallium. Cobalt was not retained by the precipitated fluorides of the rare-earth metals.

Note 2. The limit of identification of manganese was 0.5 μg., and 50 μg. was the maximum desirable for the comparison of colours. The solution could be further diluted with water. 2 μg. of manganese were found in association with 1 mg. of any of the elements mentioned in Note 1, except chromium (VI), of which only 100 μg. were permissible without the preparation of a blank experiment. Phosphate precipitates deposited by titanium, zirconium, and cerium, especially the last, tended to retain a little manganese.

Note 3. Ammonium citrate held all the metals in solution. 0.5 μg. of nickel was detectable. Excess of dimethylglyoxime commonly separated out from cold solutions without seriously affecting estimations. Nickel was detectable in association with at least a 1000-fold excess of the metals cited in Note 1, including cobalt, if sufficient reagent was present. Iron and cobalt together may form a brown precipitate with dimethylglyoxime. 25 μg. of iron, which is much more than one would expect to have here, did not upset the detection of 1 μg. of nickel in the presence of 1 mg. of cobalt, if prolonged boiling was avoided. Reprecipitation of the nickel complex corrected for a marked diminution in the bulk of the precipitate, caused by other metals and especially cobalt.

Note 4. The final concentration of 50% sulphuric acid was chosen because, at lower concentrations, the sensitivity of the test was reduced, and, at much higher concentrations, the chromotropic acid itself gave too pronounced a colour, probably because of impurity. Stannous chloride prevented or reduced the interference of iron, vanadium, tungsten, and uranium. 0.5 μg. was just detectable, and 25 μg. were set as a maximum for determinations and for the amount of reagent recommended. Colours did not deteriorate within two hours. 2 μg. of titanium were detectable in the presence of at least a 1000-fold excess of any component of the group, or of aluminium, beryllium, gallium, or zinc; and 5 μg., with a 100-fold excess of chromium, iron, uranium, or vanadium, or a 10-fold excess of tungsten.

Note 5. This test was used for the detection of zirconium in the tantalum group. Precipitation was best effected in a solution 2–5*N* in hydrochloric acid, and 1 μg. of zirconium was just detectable. The maximum amount of titanium under consideration was held adequately in solution by perhydrol, provided that heating was not prolonged. The titanium complex, if inadvertently deposited, was readily soluble in a drop of hydrochloric acid and a drop of perhydrol, whereas even a small precipitate of the zirconium complex remained undissolved. Other metals in the solution might reduce the bulk of the complex. The reprecipitation process prevented under-estimation, and at the same time eliminated any titanium that might have been carried down. 5–10 μg. of zirconium were found in association with 100 times the amount of titanium. 2 μg. were detectable in the presence of at least a 1000-fold excess of any other group component, and also of iron, gallium, aluminium, beryllium, chromium, uranium, or vanadium.

Note 6. Zinc was detected in the aluminium group by this method. Nitric acid solutions are said to give superior results, but tests made in hydrochloric acid solution were very satisfactory also, 2 μg. of zinc being found. 10 μg. of zinc were detectable in association with at least a 100-fold excess of scandium, and a 500-fold excess of manganese, indium, zirconium, gallium, iron (more reagent needed), or rare-earth group metals. Only a 100-fold excess of titanium, which hindered the deposition, was permissible. Nickel greatly hindered the precipitation and a 5-fold excess only could be tolerated. Cobalt reacted with ammonium mercury thiocyanate and, in the presence of copper sulphate, violet and black precipitates like those for zinc might be obtained. Consequently cobalt had to be completely removed before zinc was tested for.

Note 7. The extraction of cobalt and zinc from thiocyanate–fluoride solutions by means of *n*-butyl acetate was essentially complete, and practically nothing except a little indium accompanied them, even when the maximum amounts of other metals were present. After the destruction of thiocyanates, and when cobalt was absent, the direct test for zinc was applicable. Experiments made with 25 μg. of zinc in association with varying amounts of cobalt showed that the separation of 0.5 mg. of the latter by means of sodium hydroxide involved the loss of 40% of the zinc. When, therefore, more than 0.5 mg. of cobalt was present it was converted into cobaltcyanide, and zinc precipitated as zinc cobaltcyanide. As a precipitate might be produced by traces of other metals, it was essential to dissolve it, separate cobalt, and test for zinc as above. In mixtures containing in addition to 25 μg. of zinc, 5 mg. of cobalt, nickel, manganese, or rare-earth group metals, or 1 mg. of each of titanium, zirconium, indium, and scandium, the amounts of zinc retrieved were 12, 10, 10, 20, and 25 μg., respectively. The low results were attributed to difficulty in recovering all the zinc cobaltcyanide, which was very finely divided and separated extremely slowly.

Note 8. For indium and scandium no direct tests applicable in the presence or any or all of the group components were found. The tests for scandium required the absence of a great many elements, and that for indium, a considerable number. The series of simple operations prescribed separated indium and scandium, with comparatively little loss, from all the other members of the group and likely contaminants. For instance, cupferron and chloroform eliminated titanium, zirconium, iron, gallium, vanadium, and some rare-earth metals (Lundell and Hoffman, "Outlines of Methods of Chemical Analysis," 1938, 118). The butyl acetate extract contained indium, scandium, zinc, and cobalt, and contaminants, *e.g.*, aluminium, beryllium, uranium, and tungsten. By means of potassium cyanide and sodium hydroxide all of these except indium and scandium, which were precipitated as hydroxides, were taken into solution.

Note 9. The above separation of indium and scandium was so satisfactory that the precipitation of indium sulphide sufficed for the detection of the element, 5 $\mu\text{g.}$ being readily found. For a doubtful test [precipitate too pale (ZnS), or discoloured (CoS)] confirmation by means of alizarin (Wenger, *Helv. Chim. Acta*, 1945, 28, 539) is recommended. The hydrochloric acid solution of the precipitate is spotted on drop-reaction paper which has been impregnated with alizarin (0.2% in alcohol), and the spot developed over concentrated ammonia. The paper is then momentarily dipped in 10% aqueous potassium cyanide and finally soaked in saturated aqueous boric acid. Indium leaves a violet-pink spot. The cyanide destroys colours initially produced by zinc and cobalt.

Note 10. The test with alizarin-S (Beck, *Mikrochim. Acta*, 1937, 2, 9) must be made in a weakly acid solution. The colour develops slowly and its depth varies with the acid concentration. In 2*N*-acetic acid interference from rare-earth metals is prevented, and that from other metals minimised. Indium did not itself react but, in the presence of scandium, it intensified the colour. The limit of identification of scandium was 2 $\mu\text{g.}$, and amounts in excess of 25 $\mu\text{g.}$ gave too deep colours for determination. 25 $\mu\text{g.}$ of scandium required fully 0.1 ml. of the reagent. An excess is undesirable because of its own colour.

Note 11. This test was described by Beck (*loc. cit.*). Under the prescribed conditions 1 $\mu\text{g.}$ of scandium was detectable. For determinations the upper limit was 50 $\mu\text{g.}$ Many other elements fluoresced, *e.g.*, thorium, zirconium, yttrium, indium, gallium, aluminium, beryllium, and zinc. A few quenched the fluorescence of scandium. The method of isolating scandium was, however, so satisfactory that the brightest fluorescence noted in mixtures containing 5 mg. of other elements, and no scandium, corresponded to <2 $\mu\text{g.}$ of scandium.

Analysis of Mixtures.—Eight mixtures were analysed in order to test the validity of the scheme. All contained, in addition to the normal group components, 0.5 mg. of each of iron, gallium, aluminium, and vanadium as contaminants. No. 5 contained 40 mg. of rare-earth group metals (Th, Y, Ce, La, and Pr); No. 7, 8 mg. of thorium and 1 mg. of lanthanum; and No. 8, 1 mg. of yttrium. The results shown in the table are the estimated weights in mg. of the metals found. Where these differed from the weights taken, the latter are shown in parentheses.

	Co.	Ni.	Mn.	Zn.	Ti.	Zr.	In.	Sc.
1	33 (44)	0.2 (0.25)	0	0.1 (0.25)	0.2 (0.25)	0.7 (1)	0	0.1 (0.25)
2	0.25	0.25 (0.5)	34 (28)	1 (2)	0.4 (0.5)	3 (4)	0.4 (0.5)	0.5
3	5 (6)	14 (12)	6 (7)	0	2.5 (4)	8 (9)	7 (6)	3 (4)
4	0.5	0	0.4 (0.5)	0	0	0.5	0.5 (1)	5 (7)
5	1.75 (1)	1.5 (2)	3	0.15 (0.25)	6	0	0.3 (0.5)	0.15 (0.25)
6	0	1.75 (1)	0	0	1	0	7 (10)	0.5 (1)
7	43 (32)	0	0.25	0.5 (1)	0	0	0	0
8	0	27 (36)	0.7 (1)	1 (0.5)	1 (0.5)	0.2 (0.25)	0.2 (0.25)	0

The results were considered satisfactory, and all the tests, except that for zinc in the presence of much cobalt, were expeditiously carried out. It would be a great advantage if one had a sensitive test applicable to the detection of zinc in these circumstances.

I am indebted to the Trustees of the Moray Fund for a Grant which has been used for the purchase of highly purified chemicals.

250. *Magnetic Studies on Polymerisation. Part I. Magnetic Optical Rotatory Powers and Diamagnetic Susceptibilities of Certain Polymethyl Methacrylates.*

By (Miss) M. E. BEDWELL.

The magneto-optic rotatory powers and diamagnetic susceptibilities of methyl methacrylate and the polymethyl methacrylates have been measured. The results may be employed to calculate the average molecular weights of the polymers, fair agreement being obtained with values determined by a viscosity method (Schulz and Blaschke).

THE magnetic susceptibility method which Farquharson (*Trans. Faraday Soc.*, 1936, 32, 219) employed to investigate the degree of polymerisation of 2:3-dimethylbutadiene and other substances, is used in the present investigation on the polymethyl methacrylates. In addition,

another method of molecular weight determination is proposed, which is based in the magneto-optical rotatory powers of the polymers concerned.

Melville and others (General Discussion, *Trans. Faraday Soc.*, 1944, **40**, 217—273) have surveyed the end-group, osmotic, and viscosity methods for the determination of the molecular weight of higher polymers; of these, Schulz and Dinglinger (*J. pr. Chem.*, 1940, **157**, 15), Schulz and Blaschke (*Z. physikal. Chem.*, 1942, *B*, **51**, 75), Baxendale, Bywater, and Evans (*J. Polymer Sci.*, 1946, **1**, 237), and Walling and Briggs (*J. Amer. Chem. Soc.*, 1946, **68**, 1141) have shown that the viscosity method can be usefully employed to find the molecular weights of the polymethyl methacrylates, using modifications of the Staudinger equation; the present results are compared with those obtained by Schulz and Blaschke in their detailed study of the benzoyl peroxide-catalysed polymerisation of methyl methacrylate.

Magnetic Optical Rotatory Powers.—Perkin (J., 1884, **45**, 421 *et seq.*) deduced from measurements on many homologous series of organic compounds that the molecular magnetic rotation M of a substance could be expressed by

$$M = S + n\Delta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where Δ is the increase in rotation between successive members of an homologous series (the "CH₂ increment") which Perkin found experimentally to have a mean value of 1.023; n is the number of carbon atoms in the molecule; S is the "series constant" which Perkin obtained by subtracting the value of $n\Delta$ from the total observed rotation, the resulting figure being approximately constant for an homologous series of compounds and different for different series.

It was proposed to make use of this relationship in the estimation of molecular weights of higher polymers.

It follows from the above equation that a monomer is related to its polymer thus :

[illegible]

where M_p , M_m are the molecular magnetic rotations of polymer and monomer respectively, n_a is the average number of units in the molecule of polymer, and S_1 is the "series constant", which is in this case Perkin's constitutive correction for the formation of a new bond.

By definition,

$$M_p = \theta_p w_p / w; \quad M_m = \theta_m w_m / w$$

$$\theta_p = \alpha_p d / \alpha d_p; \quad \theta_m = \alpha_m d / \alpha d_m$$

where α_p , α_m , α are the observed rotations of polymer, monomer, and water respectively under the same conditions; θ_p , θ_m are the specific rotations of polymer and monomer, respectively; w_p , w_m , w are the molecular weights of polymer, monomer, and water, and d_p , d_m , d are the corresponding densities measured at the same temperature.

But $w_n = n_a \times w_m$, therefore

$$\theta_p n_a w_m / w = n_a \theta_m w_m / w + (n_a - 1) S_1 \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Hence n_a may be calculated from the experimental results.

Diamagnetic Susceptibilities.—Farquharson's expression for the mass susceptibility of a polymer is

$$\chi_s = [n_a \chi_B + (n_a - 1)\lambda] / n_a v_m \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

where w_m is the molecular weight of the monomer, χ_s is the mass susceptibility of the polymer, χ_B is the molecular susceptibility of the monomer, n_a is the degree of polymerisation, and λ is Pascal's constitutive correction constant for the bond ruptured. This equation is used for the calculation of n_a .

Average Molecular Weights.—The following table has been drawn up from measurements of magneto-optic rotatory powers and diamagnetic susceptibility which are listed later (Tables I and II); t is the polymerisation time; n_a is the average number of units in the molecule of polymer, and w_p the corresponding average molecular weight, calculated from equations (3) and (4).

t (mins.).	Magneto-optic rotation.			Diamagnetic susceptibility.		
	n_a .	$n_a \beta_p$.	w_p .	n_a .	$n_a \chi_a$.	w_p .
0	1	1.093	100	1	0.5370	100
15	2	2.088	190	1—2	0.7521	130
30	2—3	2.535	240	2—3	1.248	220
45	4	4.279	410	3—4	2.192	380
60	5	5.556	550	5	2.904	500
75	14	13.77	1390	14	8.809	1380
180	68	66.80	6750	61 *	36.06	6110
				61 *	36.06	6110

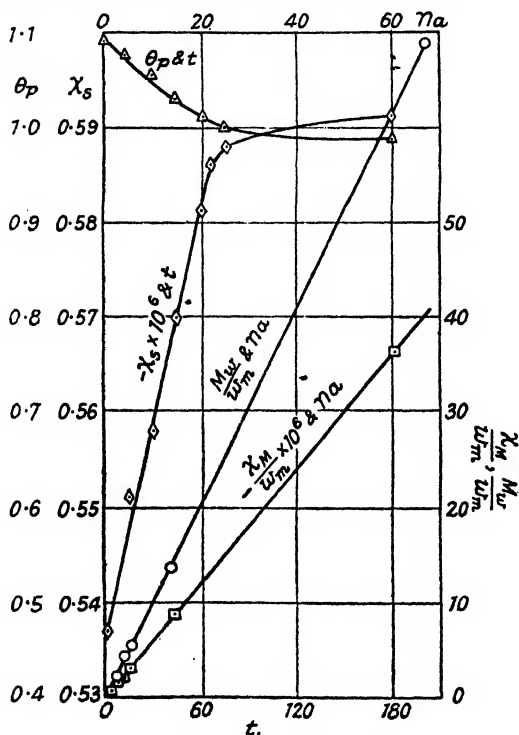

* Measurements on powder and solution, respectively.

A value of -1.112 was used for S_1 in equation (3), by analogy with ethyl crotonate, for which Perkin found an increase of rotation of 1.112 compared with ethyl butyrate; λ was assumed to be $+5.5$, which is Pascal's constitutive correction for the double bond.

The decrease in magneto-optic rotation and the increase in magnetic susceptibility which are found experimentally during polymerisation (Tables I and II) would be expected from the sign of the constants S_1 and λ above.

It will be seen that the figures for n_a and w_p obtained by the two methods agree very closely.

Extrapolation of the data of Schulz and Blaske to 80° and the benzoyl peroxide concentration used in the present investigation gives an upper limit of 5000–6000 for the molecular weight from viscosity measurements. Walling and Briggs quote higher figures in their determinations on benzoyl peroxide-free quinol-stabilised methyl methacrylate, and by analogy, an upper limit of 7000–8000 for the molecular weight may be estimated. The present figures (6750, 6110) are of the same order as the above, but from the calculation employed, it is obvious that decreasing accuracy is possible with polymers of molecular weights of the order 10^6 or higher.

Walling and Briggs found that, at 131° , concentrations of quinol of less than 1% had little effect on the molecular weight of the polymer, and it is doubtful whether the present concentration (0.03%) would cause alteration of the molecular weight to any appreciable extent at 80° .

Complete agreement is not to be expected, since both the present methods give the number-average molecular weight w_n , whereas the viscosity method gives the weight-average molecular weight w_w :

$$w_n = \Sigma w_i N_i / \Sigma N_i \text{ and } w_w = \Sigma w_i^2 N_i / \Sigma w_i N_i$$

w_i is the molecular weight averaged over the number of particles, and N_i is the number of particles of chain length i (Mark and Raff, "Higher Polymeric Reactions," New York, 1941).

Course of Polymerisation.—The polymerisation of methyl methacrylate may be explained by a chain mechanism (Mark, "Physical Chemistry of Higher Polymeric Systems", New York, 1940, 309). The methyl methacrylate molecule is thought to become activated, by heat, light, or catalyst, and in this condition it accumulates other methyl methacrylate molecules to form a long chain. Eventually the macro-molecule becomes deactivated by the saturation of the free valencies at the growing ends.

Alyea, Gartland, and Graham (*Ind. Eng. Chem.*, 1942, **34**, 458) have shown that benzoyl peroxide initiates these reaction chains, whereas quinol breaks the chains, and in doing so becomes oxidised to benzoquinone. Strain (*Ind. Eng. Chem.*, 1938, **30**, 345) has examined the polymerisation of methyl methacrylate in various organic solvents, using varying quantities of benzoyl peroxide as catalyst.

If the polymerisation is straightforward, χ_s and t will show a hyperbolic relationship (as Farquharson found to be the case with 2:3-dimethylbutadiene) and the curve for θ_p and t should also be a hyperbola. This was found to hold true in the present case (see Fig.). These results are consistent with Strain's hyperbolic percentage polymer yield-rate curves for 20% solutions of methyl methacrylate in benzene, acetone, and other solvents.

The figure also shows the linear relationships between $M_w/w_m (= n_a\theta_p)$ and n_a , and between $\chi_m/w_m (= n_a\chi_s)$ and n , in accordance with equations (3) and (4).

EXPERIMENTAL.

Measurement of Magneto-optic Rotations.—The apparatus used in these measurements has been described by Anderson, Bedwell, and Le Fèvre (this vol., p. 457). Methyl methacrylate was polymerised at 80° in the presence of a catalyst (1 mole of benzoyl peroxide to 500 moles of monomer). Samples were withdrawn at intervals, and the magneto-optic rotation measured at 20°. For the final determination, a 20% solution in methylene chloride was used. The results are shown in the figure and in Table I; t is the polymerisation time; w_1 is the weight fraction of the solute in the solution; d_{12} and α_{12} are the respective relative density and observed rotation of pure solute or solution.

By the additivity rule, $\theta_1 = (\theta_{12} - \theta_2)/w_1 + \theta_2$, where θ_1 , θ_2 , θ_{12} are the specific rotations of solute, solvent, and solution, respectively.

* $(d_1)_{20}^{20} = 1.18630$.

Measurement of Magnetic Susceptibility.—Measurements were made at 20°, using the Gouy apparatus described by Anderson, Bedwell, and Le Fèvre (*loc. cit.*). The process of polymerisation was catalysed by benzoyl peroxide at 80°, as described in the previous section. Samples were withdrawn at intervals for measurement. The final polymer was measured both in 18% solution and in the finely powdered state. The results are shown in the figure and in Table II; t is the polymerisation time, and χ_s is the specific susceptibility of the polymerising substance.

Purification of Methyl Methacrylate.—The methyl methacrylate was as supplied by I.C.I. Ltd. stabilised with quinol (0.5%). It was fractionally distilled under reduced pressure and the fraction retained (n_D^{20} 1.4143) was frozen at -70°, redistilled under high vacuum (after Walling and Briggs), and stored at -70° in the dark, with the addition of quinol as stabiliser, in the proportion of 1 mole of quinol to 4000 moles of methyl methacrylate.

251. Synthetic Antimalarials. Part XXI. 4-Arylamino-6-aminoalkylaminopyrimidines. Further Variations.

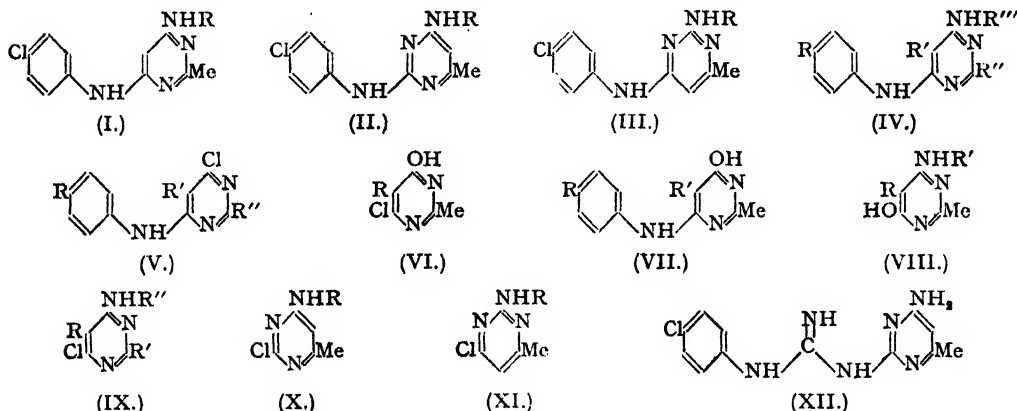

By F. R. BASFORD, F. H. S. CURD, E. HOGGARTH, and F. L. ROSE.

An alternative method of synthesis has been devised for the inactive 4-arylamino-6-aminoalkylamino-2-methylpyrimidines (type I) described in Part VIII (*J.*, 1946, 713), and, employing both this and the original route, substituents such as methyl, ethyl, and phenyl have been introduced into position 5 of the pyrimidine nucleus. These new derivatives were inactive, as were also related compounds in which the 2-methyl group was replaced by amino.

The importance of the aminoalkylamino-side chain in the active 2-arylamino-4-aminoalkylamino- and 4-arylamino-2-aminoalkylamino-6-methylpyrimidines described earlier in this series (*J.*, 1946, 345, 351, 366, 370, 378) has been shown by the lack of activity in compounds, now synthesised, in which that grouping is replaced by primary amino.

Differences in chemical reactivity of several related chloropyrimidine derivatives are discussed.

CHRONOLOGICALLY the work described in this paper follows that reported in Part VIII (*J.*, 1946, 713) which concerned the synthesis of a variety of 4-arylamino-6-aminoalkylamino-2-methylpyrimidines including compounds of type (I; R = dialkylaminoalkyl). All these compounds were found to be without activity against *P. gallinaceum* in chicks. In the same paper we drew attention to the fact that in compounds of type (I) there do not exist two amidine units capable of independent tautomerism as are found in the two isomeric types (II) and (III).

Since one important development of our work (see Part X, *J.*, 1946, 729) was in part based on the recognition of the possible significance of this difference, it seemed desirable to demonstrate with as much certainty as possible that antimalarial activity could not be developed in compounds of type (I). Thus, for example, in a series of simple 2-amino-4-aminoalkylaminopyrimidines, Hull, Lovell, Openshaw, Payman, and Todd (*J.*, 1946, 357) have shown that the introduction of a substituent into position 5 of the pyrimidine nucleus induced antimalarial activity. Clearly, this was a device that needed to be tried in the present instance, although it was appreciated that the two cases might not be comparable since it had been suggested (*idem, ibid.*) that the activity of the simple pyrimidines might be associated with an interference with nucleoside synthesis and the 5-substituent gave a closer structural resemblance to the purines, whereas we in the past have stressed the relationship of the anilino-pyrimidines to riboflavin. The new preparations were of type (IV; R' = Me, Et, or Ph; R'' = Me). Not all of these were made by the general method described in the earlier paper, namely through the reaction of an aminoalkylamine with the appropriately substituted 4-chloro-6-arylamino-2-methylpyrimidine (V; R'' = Me), itself obtained either directly by condensing a 4:6-dichloro-2-methylpyrimidine with an arylamine, or indirectly from a 4-chloro-6-hydroxy-2-methylpyrimidine (VI) by interaction with an arylamine followed by treatment of the resulting 4-arylamino-6-hydroxy-2-methylpyrimidine (VII) with phosphoryl chloride. A useful alternative method of synthesis has now been developed in which the arylamino- and aminoalkylamino-groups are introduced in the reverse order. The method is best illustrated by its application to the original type (I). β -Diethylaminoethylamine and γ -diethylaminopropylamine when heated with 4-chloro-6-hydroxy-2-methylpyrimidine (VI; R = H) gave respectively

4- β -diethylaminoethylamino- (VIII; $R = H$, $R' = [CH_2]_2 \cdot NEt_2$) and 4- γ -diethylaminopropylamino-6-hydroxy-2-methylpyrimidine (VIII; $R = H$, $R' = [CH_2]_3 \cdot NEt_2$) as their hydrochlorides. Treatment of these hydrochlorides with boiling phosphoryl chloride converted them into 4-chloro-6- β -diethylaminoethylamino- (IX; $R = H$, $R' = Me$, $R'' = [CH_2]_2 \cdot NEt_2$) and 4-chloro-6- γ -diethylaminopropylamino-2-methylpyrimidine (IX; $R = H$, $R' = Me$, $R'' = [CH_2]_3 \cdot NEt_2$) respectively. When a similar series of reactions was tried starting with 8-diethylamino- α -methylbutylamine it was found impossible to crystallise the intermediate 4-8-diethylamino- α -methylbutylamino-6-hydroxy-2-methylpyrimidine hydrochloride, but treatment of the crude product with phosphoryl chloride gave 4-chloro-6-8-diethylamino- α -methylbutylamino-2-methylpyrimidine (IX; $R = H$, $R' = Me$, $R'' = CHMe \cdot [CH_2]_3 \cdot NEt_2$) in good yield. The above compounds of type (IX) underwent smooth reaction with *p*-chloroaniline in boiling aqueous solution as their monohydrochlorides in presence of a little extra hydrochloric acid, to give the corresponding 4-*p*-chloroanilino-6-dialkylaminoalkylamino-2-methylpyrimidines (I; $R = [CH_2]_2 \cdot NEt_2$, $[CH_2]_3 \cdot NEt_2$, or $CHMe \cdot [CH_2]_3 \cdot NEt_2$) described in Part VIII (*loc. cit.*). In these reactions with *p*-chloroaniline no obvious differences could be detected between the reactivity of the 4-chloro-6-dialkylaminoalkylamino-2-methylpyrimidines and the isomeric 2-chloro-4-dialkylaminoalkylamino-6-methylpyrimidines (X) (see Part XV, this vol., p. 783) and 4-chloro-2-dialkylaminoalkylamino-6-methylpyrimidines (XI) (Part VI, *J.*, 1946, 370). No appreciable condensation occurred, even in the last two instances, when the chloropyrimidines were employed as free bases with addition of a trace of hydrochloric acid. The need for slightly more than one equivalent of acid to facilitate the reaction suggested that the chlorine atom was only labile after salt formation had occurred on the dialkylamino-group of the side chain.

A comparison with the three isomeric types of chlorodialkylaminoalkylaminomethylpyrimidines was provided by the corresponding unsubstituted amino-compounds. Like 2-chloro-4-amino- (X; $R = H$) and 4-chloro-2-amino-6-methylpyrimidine (XI; $R = H$), 4-chloro-6-amino-2-methylpyrimidine (IX; $R = R' = H$, $R' = Me$) reacted readily with *p*-chloroaniline in boiling aqueous solution in presence of only a little hydrochloric acid. The apparent normal reactivity of the 4-chloro-6-amino- and 4-chloro-6-dialkylaminoalkylamino-2-methylpyrimidines in comparison with their respective isomers was in direct contrast to that of the 4-chloro-6-aryl-amino-2-methylpyrimidines (IX; $R = H$, $R' = Me$, $R'' = aryl$) which were found to be less reactive than the corresponding 2-chloro-4-aryl-amino- (X; $R = aryl$) and 4-chloro-2-aryl-amino-6-methylpyrimidines (XI; $R = aryl$) (see Part VIII, *loc. cit.*). This conforms with the suggestion there advanced that in arylaminopyrimidines there is a strong tendency for the linking nitrogen atom to conjugate with the benzene ring.

Several points may be noted in connection with the synthesis of compounds of type (IV; $R'' = Me$) described in detail in the experimental section. In the preparation of 4-chloro-6-*p*-anisidino-2 : 5-dimethylpyrimidine (V; $R = OMe$, $R' = R'' = Me$), required for the synthesis of (IV; $R = OMe$, $R' = R'' = Me$, $R''' = [CH_2]_2 \cdot NEt_2$), by condensation of 4 : 6-dichloro-2 : 5-dimethylpyrimidine with *p*-anisidine in aqueous acetone catalysed by hydrochloric acid, no formation of di-condensation product was observed. Even the use of two molecular proportions of *p*-anisidine gave exclusively 4-chloro-6-*p*-anisidino-2 : 5-dimethylpyrimidine in contrast to the formation mainly of 4 : 6-di-*p*-anisidino-2-methylpyrimidine from 4 : 6-dichloro-2-methylpyrimidine and two equivalents of *p*-anisidine under identical conditions (see Part VIII). This steric effect of a 5-substituent was also noticed during the synthesis of 4-*p*-chloroanilino-6- γ -diethylaminopropylamino-2-methyl-5-ethylpyrimidine (IV; $R = Cl$, $R' = Et$, $R'' = Me$, $R''' = [CH_2]_3 \cdot NEt_2$). Whereas, as noted above, compounds of type (IX; $R' = Me$, $R'' = dialkylaminoalkyl$) containing no substituent in the 5-position ($R = H$) condensed readily on boiling with *p*-chloroaniline in aqueous solution containing a little more than one equivalent of hydrochloric acid, no corresponding condensation occurred between 4-chloro-6- γ -diethylaminopropylamino-2-methyl-5-ethylpyrimidine (IX; $R = Et$, $R' = Me$, $R'' = [CH_2]_3 \cdot NEt_2$) and *p*-chloroaniline under similar conditions. Higher temperatures were found to be necessary to effect condensation. The steric effect of a 5-phenyl group was even more marked than that of methyl or ethyl. Thus the reaction of *p*-chloroaniline with 4 : 6-dichloro-5-phenyl-2-methylpyrimidine to give 4-chloro-6-*p*-chloroanilino-5-phenyl-2-methylpyrimidine (V; $R = Cl$, $R' = Ph$, $R'' = Me$) failed completely in boiling aqueous acetone with added hydrochloric acid, gave small yields in boiling alcohol, but succeeded at 115–120° in an equivalent of acetic acid. Tests using *P. gallinaceum* in chicks, carried out by our colleague, Dr. D. G. Davey, with the compounds of type (IV; $R'' = Me$), showed that the introduction of a substituent into the 5-position of type (I) failed to confer antimalarial activity.

The necessity for the aminoalkyl group (R) in types (II) and (III) to promote antimalarial

activity was shown by the inactivity in the same test of 4-amino-2-*p*-chloroanilino- (II; R = H) and 2-amino-4-*p*-chloroanilino-6-methylpyrimidine (III; R = H). The former was made by condensing (X; R = H) with *p*-chloroaniline, as mentioned above, and also by the action of ammonia on 4-chloro-2-*p*-chloroanilino-6-methylpyrimidine at 140–150°. When, however, the action of ammonia on 4-chloro-2-*p*-chlorophenylguanidino-6-methylpyrimidine was tried with a view to the preparation of (XII), in order to assess the need for the aminoalkyl group in the active 2-*p*-chlorophenylguanidino-4-aminoalkylamino-6-methylpyrimidines described in Part IV (J., 1946, 362), it was found that 2-amino-4-*p*-chloroanilino-6-methylpyrimidine was the main product. Hydrolysis of 2-*p*-chlorophenylguanidino-4-β-diethylaminoethylamino-6-methylpyrimidine with *N*-hydrochloric acid has been shown by Spinks and Tottey (*Ann. Trop. Med. Parasit.*, 1945, 39, 190) to give *p*-chloroaniline, 2-amino-4-β-diethylaminoethylamino-6-methylpyrimidine, ammonia, and carbon dioxide. Analogously, it is suggested that 4-chloro-2-*p*-chlorophenylguanidino-6-methylpyrimidine by ammonolysis gave *p*-chloroaniline and 4-chloro-2-amino-6-methylpyrimidine which then interacted to yield (III; R = H).

As a further extension of the investigation of compounds of type (IV) it seemed desirable to study compounds containing an amino-group in the 2-position (R' = NH₂). The presence of such a group, in association with the anilino-residue, would provide the two linked independent amidine units which are a feature of types (II) and (III) without reference to the aminoalkyl-amino-group, and the only function required of the latter would be that of conditioning the pharmacology of the drug molecule.

Like 4 : 6-dichloro-2-methylpyrimidine, 4 : 6-dichloro-2-aminopyrimidine reacted with *p*-chloroaniline in boiling aqueous acetone in presence of a little hydrochloric acid as catalyst to give 4-chloro-2-amino-6-*p*-chloroanilinopyrimidine (V; R = Cl, R' = H, R'' = NH₂). This condensed smoothly with dialkylaminoalkylamines at 150–160°. In this way the following were prepared: 2-amino-4-*p*-chloroanilino-6-β-diethylaminoethylamino- (IV; R = Cl, R' = H, R'' = NH₂, R''' = [CH₂]₂·NEt₂) and 2-amino-4-*p*-chloroanilino-6-γ-diethylaminopropylaminopyrimidine (IV; R = Cl, R' = H, R'' = NH₂, R''' = [CH₂]₃·NEt₂) and the corresponding compounds containing the β-dimethylaminoethylamino-, γ-dimethylaminopropylamino-, and δ-diethylamino-α-methylbutylamino- side chains. 2-Amino-4-*p*-chloroanilino-6-β-diethylaminoethylaminopyrimidine was also obtained by reaction of *p*-chloroaniline hydrochloride with 4-chloro-2-amino-6-β-diethylaminoethylaminopyrimidine (IX; R = H, R' = NH₂, R'' = [CH₂]₂·NEt₂) which resulted from condensation of β-diethylaminoethylamine with 4 : 6-dichloro-2-aminopyrimidine. The former method of synthesis was also employed for the preparation of 2-amino-4-*p*-anisidino- (IV; R = OMe, R' = H, R'' = NH₂, R''' = [CH₂]₂·NEt₂) and 2-amino-4-*p*-toluidino-6-β-diethylaminoethylaminopyrimidine (IV; R = Me, R' = H, R'' = NH₂, R''' = [CH₂]₂·NEt₂).

None of these compounds containing an amino-group in the 2-position of the pyrimidine nucleus exhibited any antimalarial activity, nor did any of the several 5-ethyl or 5-phenyl derivatives which were prepared (*vide infra*). Similar lack of activity characterised a series of 4-chloro-2-amino-6-aminokylamino-5-ethyl- and -phenyl-pyrimidines which thus resemble the related 4-chloro-2-amino-6-dialkylaminoalkylamino-5-methylpyrimidines investigated by Hull, Lovell, Openshaw, and Todd (Part XI, this vol., p. 41).

EXPERIMENTAL.

4-β-Diethylaminoethylamino-6-hydroxy-2-methylpyrimidine (VIII; R = H, R' = [CH₂]₂·NEt₂).—4-Chloro-6-hydroxy-2-methylpyrimidine (14.4 g.) (Part VIII, *loc. cit.*) and β-diethylaminoethylamine (11.6 g.) were heated at 150–160° for 8 hours to give 4-β-diethylaminoethylamino-6-hydroxy-2-methylpyrimidine hydrochloride which separated from moist alcohol-ethyl acetate as a hydrate which did not lose water on drying at 100°; colourless laminae, m. p. 193–195° (Found : C, 47.9; H, 7.9; N, 20.7; Cl, 13.0. C₁₁H₂₀ON₄·HCl·H₂O requires C, 47.4; H, 7.5; N, 20.1; Cl, 12.8%).

4-γ-Diethylaminopropylamino-6-hydroxy-2-methylpyrimidine (VIII; R = H, R' = [CH₂]₃·NEt₂).—By substituting γ-diethylaminopropylamine for the β-diethylaminoethylamine in the above preparation this was obtained as its monohydrochloride which crystallised from alcohol-ethyl acetate as colourless needles, m. p. 87–89° (after drying in air at room temperature) [Found : loss on drying at 100°, 6.4, 6.7. C₁₅H₂₄ON₄·HCl·1.5H₂O requires loss (for 1 H₂O), 6.0%] or 186–188° (after drying at 100°) (Found : C, 51.2; H, 8.4; N, 19.7; Cl, 12.3. C₁₅H₂₄ON₄·HCl·0.5H₂O requires C, 50.8; H, 8.5; N, 19.75; Cl, 12.5%).

4-Chloro-6-β-diethylaminoethylamino-2-methylpyrimidine (IX; R = H, R' = Me, R'' = [CH₂]₂·NEt₂).—4-β-Diethylaminoethylamino-6-hydroxy-2-methylpyrimidine hydrochloride (20 g.) and phosphoryl chloride (75 c.c.) were boiled under reflux for 3 hours. After removal of most of the excess of phosphoryl chloride under reduced pressure, the residue was poured on ice, and the solution made strongly alkaline with sodium hydroxide and extracted with chloroform. The chloroform solution was shaken several times with 5% acetic acid and the combined acetic acid extracts were treated with sodium hydroxide and shaken with chloroform. Evaporation of the dried (K₂CO₃) extract gave the chloropyrimidine as

a colourless oil (yield, 9.9 g.), b. p. 136—137°/0.15 mm. (Found: C, 54.0; H, 7.8. $C_{11}H_{19}N_4Cl$ requires C, 54.4; H, 7.8%). It gave a *dipicrate* which crystallised from methanol as yellow laminae, m. p. 144—145° (Found: C, 39.7; H, 3.8; N, 20.1. $C_{11}H_{19}N_4Cl \cdot 2C_6H_3O_7N_3$ requires C, 39.4; H, 3.6; N, 20.0%).

4-Chloro-6- γ -diethylaminopropylamino-2-methylpyrimidine (IX; R = H, R' = Me, R'' = $[CH_2]_3 \cdot N \cdot Et_2$), prepared similarly from 4- γ -diethylaminopropylamino-6-hydroxy-2-methylpyrimidine hydrochloride (dried at 100°) (17.5 g.) and phosphoryl chloride (75 c.c.), was obtained as a colourless oil (yield, 8.7 g.), b. p. 143—145°/0.15 mm. (Found: C, 55.9; H, 8.1; N, 21.7; Cl, 13.4. $C_{12}H_{21}N_4Cl$ requires C 56.1; H, 8.2; N, 21.8; Cl, 13.8%). The *dipicrate* crystallised from methanol in yellow laminae, m. p. 158—159° (Found: C, 40.2; H, 3.6; N, 19.8. $C_{12}H_{21}N_4Cl \cdot 2C_6H_3O_7N_3$ requires C 40.3; H, 3.8; N, 19.6%).

Condensation of 4-Chloro-6- β -diethylaminoethylamino-2-methylpyrimidine with p-Chloroaniline.—A mixture of (IX; R = H, R' = Me, R'' = $[CH_2]_3 \cdot N \cdot Et_2$) (4.85 g.), *p*-chloroaniline (2.55 g.), water (25 c.c.), and 10*N*-hydrochloric acid (2.2 c.c.) was refluxed for 6 hours. The cooled solution was treated with sodium hydroxide; the product then separated as an oil which soon solidified. The solid was collected and dissolved in 5% acetic acid, and the solution was treated with decolourising carbon and filtered. The product was then reprecipitated by the addition of sodium hydroxide, filtered off, dried, and crystallised from light petroleum (b. p. >120°) (yield, 86.2%); it had m. p. 148° undepressed on admixture with 4-*p*-chloroanilino-6- β -diethylaminoethylamino-2-methylpyrimidine (see Part VIII) (Found: C, 61.1; H, 7.0; N, 21.2; Cl, 10.3. Calc. for $C_{17}H_{24}N_6Cl$: C, 61.3; H, 7.2; N, 21.0; Cl, 10.5%).

Condensation of 4-Chloro-6- γ -diethylaminopropylamino-2-methylpyrimidine with p-Chloroaniline.—4-Chloro-6- γ -diethylaminopropylamino-2-methylpyrimidine (5.1 g.), *p*-chloroaniline (2.55 g.), water (25 c.c.), and 10*N*-hydrochloric acid (2.2 c.c.) were boiled under reflux for 2 hours, and the solution was cooled and made alkaline with sodium hydroxide. The precipitated oil, isolated with chloroform, was extracted with 5% acetic acid. Basification (with sodium hydroxide) of the clarified acetic acid solution and extraction with chloroform followed by evaporation of the dried solution gave the base which crystallised from light petroleum (b. p. >120°); it had m. p. 129—131° identical with 4-*p*-chloroanilino-6- γ -diethylaminopropylamino-2-methylpyrimidine made by the method of Part VIII (Found: C, 62.1; H, 7.5; N, 19.9. Calc. for $C_{18}H_{26}N_6Cl$: C, 62.2; H, 7.5; N, 20.1%).

4-Chloro-6- δ -diethylamino- α -methylbutylamino-2-methylpyrimidine (IX; R = H, R' = Me, R'' = $CHMe \cdot [CH_2]_3 \cdot N \cdot Et_2$).—4-Chloro-6-hydroxy-2-methylpyrimidine (28.9 g.) and δ -diethylamino- α -methylbutylamine (31.6 g.) were mixed and heated at 150—160° for 8 hours. To the cooled residue phosphoryl chloride (180 c.c.) was added, the mixture refluxed for 3 hours, excess of phosphoryl chloride removed under reduced pressure, and the residue poured on ice. The resulting solution was made alkaline with sodium hydroxide and extracted with chloroform. Evaporation of the dried (K_2CO_3) chloroform solution and distillation of the residual oil gave the *chloropyrimidine* (yield, 36.4 g.), b. p. 168—170°/0.125 mm. (Found: C, 59.2; H, 8.3; N, 19.5; Cl, 12.7. $C_{14}H_{22}N_4Cl$ requires C, 59.0; H, 8.8; N, 19.7; Cl, 12.5%). The *dipicrate* crystallised from alcohol-2-ethoxyethanol in small yellow laminae, m. p. 171—173° (Found: C, 41.7; H, 4.2; N, 19.1. $C_{14}H_{22}N_4Cl \cdot 2C_6H_3O_7N_3$ requires C, 42.0; H, 4.2; N, 18.9%).

Condensation of 4-Chloro-6- δ -diethylamino- α -methylbutylamino-2-methylpyrimidine with p-Chloroaniline.—4-Chloro-6- δ -diethylamino- α -methylbutylamino-2-methylpyrimidine (5.7 g.), *p*-chloroaniline (2.55 g.), water (25 c.c.), and 10*N*-hydrochloric acid (2.2 c.c.) were refluxed for 2 hours, and the resulting solution was cooled and made alkaline with sodium hydroxide. The precipitated oil was collected and extracted with 5% acetic acid, and the acetic acid extract clarified with carbon, filtered, and added to excess of sodium hydroxide solution. The oily product was extracted with chloroform, and the solution dried and evaporated. Distillation of the residue gave 4-*p*-chloroanilino-6- δ -diethylamino- α -methylbutylamino-2-methylpyrimidine, b. p. 220—225°/0.15 mm., identified as its *dipicrate*, m. p. 159—161° (Found: C, 46.2; H, 4.3; N, 18.2. $C_{20}H_{30}N_6Cl \cdot 2C_6H_3O_7N_3$ requires C, 46.1; H, 4.3; N, 18.5%). In Part VIII (*loc. cit.*) the m. p. of this picrate is given as 149—151°. The discrepancy is thought to be due to dimorphism, since repeat preparations of this picrate sometimes gave m. p. 149—151°, sometimes 159—161°, and sometimes intermediately. The exact conditions of crystallisation to obtain the two forms were not fully elucidated, but a preparation of the picrate from base made according to the method of Part VIII which had m. p. 159—161° (Found: C, 45.9; H, 4.3; N, 18.6%) showed no depression with the picrate described above.

4-Amino-2-*p*-chloroanilino-6-methylpyrimidine (II; R = H).—(a) 2-Chloro-4-amino-6-methylpyrimidine (7.2 g.), *p*-chloroaniline (6.4 g.), water (25 c.c.), and 10*N*-hydrochloric acid (0.5 c.c.) were refluxed for 1 hour. A clear solution was obtained after a few minutes refluxing, and the product then gradually separated. The mixture was diluted with water and made alkaline with ammonia, and the solid collected. The solid was dissolved in alcohol, and the solution made alkaline with ammonia and poured into water. The precipitated product was extracted with chloroform, and the solution dried (Na_2SO_4) and evaporated. Crystallisation of the residue from benzene-light petroleum gave colourless needles, m. p. 121—123°.

(b) 4-Chloro-2-*p*-chloroanilino-6-methylpyrimidine (10 g.) and aqueous ammonia (30 c.c.) were heated in a sealed tube at 140—150° for 12 hours. The contents of the tube were diluted with water and extracted with chloroform. Evaporation of the dried chloroform extract gave an oil which was purified by vacuum distillation (b. p. 190—192°/0.5 mm.). Crystallisation from benzene-light petroleum gave 4-amino-2-*p*-chloroanilino-6-methylpyrimidine, m. p. 121—122° undepressed in admixture with material made by method (a) (Found: C, 56.7; H, 4.5; Cl, 15.1. $C_{11}H_{11}N_4Cl$ requires C, 56.3; H, 4.7; Cl, 15.1%) (4394).

2-Amino-4-*p*-chloroanilino-6-methylpyrimidine (III; R = H).—4-Chloro-2-amino-6-methylpyrimidine (7.2 g.), *p*-chloroaniline (6.4 g.), water (25 c.c.), and 10*N*-hydrochloric acid (0.5 c.c.) were refluxed for 1 hour. The reaction mixture was cooled, diluted with water, and made alkaline with ammonia. The precipitated product was filtered off, washed with water, and crystallised from aqueous alcohol, giving 2-amino-4-*p*-chloroanilino-6-methylpyrimidine as colourless needles, m. p. 216—218° (Found: Cl, 15.2. $C_{11}H_{11}N_4Cl$ requires Cl, 15.1%) (4618).

Reaction of 4-Chloro-2-p-chlorophenylguanidino-6-methylpyrimidine with Ammonia (Experiment by Dr. P. A. Barrett).—4-Chloro-2-p-chlorophenylguanidino-6-methylpyrimidine (5 g.) and saturated alcoholic ammonia (25 c.c.) were heated in a sealed tube at 175° for 12 hours. The contents of the tube were evaporated to dryness and the residue was stirred with water. The resulting solid on fractional crystallisation from dilute alcohol gave 2-amino-4-p-chloroanilino-6-methylpyrimidine, m. p. and mixed m. p. 216–218° (Found: C, 56.2; H, 4.4; N, 23.7; Cl, 15.4. Calc. for $C_{11}H_{11}N_4Cl$: C, 56.3; H, 4.7; N, 23.9; Cl, 15.1%), as the less soluble fraction and p-chloroaniline as the more soluble.

4-Amino-6-p-chloroanilino-2-methylpyrimidine (I; R = H).—4-Chloro-6-amino-2-methylpyrimidine (7.2 g.), p-chloroaniline (6.4 g.), water (25 c.c.), and 10N-hydrochloric acid (0.5 c.c.) were refluxed for 1 hour. The reaction mixture was diluted with water and made alkaline with ammonia, and the product filtered off. The product was dissolved in alcohol, and the solution made alkaline with ammonia and poured into water. The precipitated product was filtered off and crystallised from aqueous alcohol, giving the pyrimidine as colourless flat prisms, m. p. 192–194° (Found: C, 56.4; H, 4.6; Cl, 15.2. $C_{11}H_{11}N_4Cl$ requires C, 56.3; H, 4.7; Cl, 15.1%).

4-Chloro-6-p-chloroanilino-2:5-dimethylpyrimidine (V; R = Cl, R' = R'' = Me).—(a) 4:6-Dichloro-2:5-dimethylpyrimidine (8.85 g.) (Huber and Holscher, *Ber.*, 1938, 71, 87), p-chloroaniline (6.4 g.), water (40 c.c.), acetone (20 c.c.), and 10N-hydrochloric acid (2 c.c.) were refluxed for 2 hours. The resulting solution was diluted with water and ammonia added to give an alkaline reaction to Brilliant-yellow. The precipitated base was filtered off, dissolved in alcohol with the addition of a little ammonia, and poured into water. The solid was collected, washed with water, dried, and crystallised from alcohol, giving colourless thick prisms (9 g.), m. p. 176–177° (Found: C, 54.1; H, 3.9; N, 16.2; Cl, 26.2. $C_{12}H_{11}N_4Cl_2$ requires C, 53.7; H, 4.1; N, 15.7; Cl, 26.5%).

(b) 4:6-Dichloro-2:5-dimethylpyrimidine (5.3 g.) and p-chloroaniline (4.2 g.) were heated in acetic acid (30 c.c.), containing a crystal of potassium iodide, at 40° for 20 hours. Addition of sodium acetate (4 g.) and dilution with water gave 4-chloro-6-p-chloroanilino-2:5-dimethylpyrimidine which was filtered off, washed with water, and dried. It had m. p. and mixed m. p. 176° after crystallisation from benzene-light petroleum (Found: Cl, 26.5%).

4-Chloro-6-hydroxy-2:5-dimethylpyrimidine (VI; R = Me).—4:6-Dichloro-2:5-dimethylpyrimidine (25 g.), water (250 c.c.), and hydrochloric acid (100 c.c.) were boiled together under reflux for 1 hour (complete homogeneity was obtained after $\frac{1}{2}$ hour). The solution was cooled, made alkaline with sodium hydroxide, and then acidified with acetic acid. The precipitated product was filtered off and purified by dissolution in ammonia and reprecipitation with acetic acid. After drying, it crystallised from alcohol in colourless slender prisms (yield 16.3 g.), m. p. 225° (Found: C, 45.5; H, 4.4; N, 17.5; Cl, 22.8. $C_8H_8ON_4Cl$ requires C, 45.4; H, 4.4; N, 17.7; Cl, 22.4%).

4-Chloro-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine (IX; R = R' = Me, R'' = $[CH_2]_2 \cdot NEt_2$).—4-Chloro-6-hydroxy-2:5-dimethylpyrimidine (25 g.) and β -diethylaminoethylamine (18.3 g.) were mixed and heated at 150–160° for 8 hours. A portion of the resulting solid, on treatment with excess of picric acid in methanol solution, gave 4- β -diethylaminoethylamino-6-hydroxy-2:5-dimethylpyrimidine *dipicrate* which crystallised from alcohol in yellow rectangular prisms, m. p. 154° (Found: C, 41.6; H, 4.2; N, 20.2. $C_{15}H_{22}ON_4 \cdot 2C_6H_3O_7N_3$ requires C, 41.4; H, 4.0; N, 20.1%). The remainder of the hydrochloride was refluxed with phosphoryl chloride (220 c.c.) for 5 hours and the excess of phosphoryl chloride then removed by distillation under reduced pressure and the residue poured on ice. Addition of sodium hydroxide to the solution liberated the chloro-compound which was extracted with chloroform, and the extract was dried and evaporated. The residue was distilled in a vacuum giving 4-chloro-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine (21.9 g.), b. p. 139°/0.085 mm. (Found: C, 56.1; H, 8.2; Cl, 13.5. $C_{12}H_{17}N_4Cl$ requires C, 56.1; H, 8.2; Cl, 13.8%). It formed a *hydrate* which crystallised from light petroleum (b. p. 60–80°) in colourless thick laminae, m. p. 80° (Found: C, 52.6; H, 8.4; N, 20.3. $C_{12}H_{17}N_4Cl \cdot H_2O$ requires C, 52.5; H, 8.4; N, 20.4%), and a *dipicrate* which separated from alcohol in yellow laminae, m. p. 143° (Found: N, 19.5. $C_{12}H_{17}N_4Cl \cdot 2C_6H_3O_7N_3$ requires N, 19.6%).

4- δ -Diethylamino- α -methylbutylamino-6-hydroxy-2:5-dimethylpyrimidine (VIII; R = Me, R' = CHMe $[CH_2]_3 \cdot NEt_2$).—4-Chloro-6-hydroxy-2:5-dimethylpyrimidine (31.7 g.) and δ -diethylamino- α -methylbutylamine (31.6 g.) were mixed and heated at 150–160° for 8 hours with stirring to give, on cooling, a viscous mass of 4- δ -diethylamino- α -methylbutylamino-6-hydroxy-2-methylpyrimidine hydrochloride which could not be crystallised. The *dipicrate*, prepared from the hydrochloride with excess of picric acid in methanol, crystallised from alcohol; m. p. 163–164° (Found: C, 43.9; H, 4.8. $C_{18}H_{28}ON_4 \cdot 2C_6H_3O_7N_3$ requires C, 43.9; H, 4.6%).

4-Chloro-6- δ -diethylamino- α -methylbutylamino-2:5-dimethylpyrimidine (IX; R = R' = Me, R'' = CHMe $[CH_2]_3 \cdot NEt_2$).—Phosphoryl chloride (225 c.c.) was added to the above crude hydrochloride (62 g.) and the mixture boiled under reflux for 4 hours. Most of the excess of phosphoryl chloride was removed under diminished pressure, the residue poured on ice, and, after solution had occurred, sodium hydroxide added to alkalinity, the oily product extracted with chloroform, and the extract dried and evaporated. Distillation of the residue gave the *chloropyrimidine* as a colourless oil (yield, 22.05 g.), b. p. 144–145°/0.055 mm. (Found: Cl, 12.1, 12.3. $C_{15}H_{21}N_4Cl$ requires Cl, 11.9%). A crystalline derivative was not obtained.

4-p-Chloroanilino-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine (IV; R = Cl, R' = R'' = Me, R''' = $[CH_2]_2 \cdot NEt_2$).—(a) 4-Chloro-6-p-chloroanilino-2:5-dimethylpyrimidine (14.6 g.), β -diethylaminoethylamine (15 g.), and a crystal of potassium iodide were heated at 150–160° for 6 hours with stirring. The resulting melt was dissolved in dilute hydrochloric acid, and the solution made alkaline with sodium hydroxide and extracted with chloroform. After removal of the solvent the residue was stirred with 5% acetic acid, and the extract separated, stirred with decolourising carbon, and filtered. The filtrate was then made strongly alkaline with sodium hydroxide and extracted with chloroform, and the extract dried and evaporated. Distillation of the residual oil afforded 4-p-chloroanilino-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine as a colourless oil (yield, 11.6 g.), b. p. 200°/0.07 mm. (Found: C, 61.6; H, 7.5; N, 19.7; Cl, 10.2. $C_{15}H_{18}N_4Cl$ required C, 62.2; H, 7.5; N, 20.1; Cl, 10.2%). The base was converted into its *dihydrochloride* by dissolving in 2N-hydrochloric acid and

evaporating the solution to dryness. The residue was dried and freed from adhering hydrochloric acid by dissolving in alcohol and evaporation to dryness under reduced pressure several times. Crystallisation from alcohol-ethyl acetate then gave thin colourless prisms, m. p. 263–264° (Found: C, 51.0; H, 6.4; N, 16.4; Cl, 16.2. $C_{18}H_{22}N_6Cl_2 \cdot 2HCl$ requires C, 51.4; H, 6.7; N, 16.65; Cl, 16.9%) (3990).

(b) A mixture of 4-chloro-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine (5.13 g.), *p*-chloroaniline hydrochloride (3.28 g.), and hydrochloric acid (0.25 c.c.) was heated at 150–160° for 6 hours. By direct crystallisation of the resulting solid melt from alcohol-ethyl acetate, 4-*p*-chloroanilino-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine dihydrochloride was obtained (yield, 5.7 g.), m. p. and mixed m. p. 262–264° (Found: C, 51.2; H, 6.1; N, 16.4; Cl, 16.5%).

4-*p*-Chloroanilino-6- γ -diethylaminopropylamino-2:5-dimethylpyrimidine (IV; R = Cl, R' = R'' = Me, R''' = $[CH_2]_3 \cdot NEt_3$), prepared by method (a) above from 4-chloro-6-*p*-chloroanilino-2:5-dimethylpyrimidine and γ -diethylaminopropylamine, formed a colourless viscous oil, b. p. 204°/0.045 mm. (Found: C, 62.9; H, 7.8; N, 18.8; Cl, 9.8. $C_{18}H_{22}N_6Cl$ requires C, 63.1; H, 7.7; N, 19.4; Cl, 9.8%) which gave a dihydrochloride as colourless prisms from alcohol-ethyl acetate, m. p. 217–218° (Found: C, 48.8; H, 7.1; N, 14.9; Cl, 15.1. $C_{18}H_{22}N_6Cl_2 \cdot 2H_2O$ requires C, 48.5; H, 7.2; N, 14.9; Cl, 15.1%) (5507).

4-*p*-Chloroanilino-6- γ -dimethylaminopropylamino-2:5-dimethylpyrimidine (IV; R = Cl, R' = R'' = Me, R''' = $[CH_2]_3 \cdot NMe_2$), prepared in a corresponding manner using γ -dimethylaminopropylamine, was obtained as colourless prisms from light petroleum (b. p. 60–80°), m. p. 105° (Found: C, 61.2; H, 7.0; N, 20.6. $C_{17}H_{20}N_6Cl$ requires C, 61.2; H, 7.2; N, 21.0%). It gave a dihydrochloride which crystallised from alcohol-ethyl acetate in tiny colourless prisms, m. p. 275–276° (decomp.) (the m. p. varied slightly with the rate of heating) (Found: C, 49.9; H, 6.3; N, 17.3; Cl, 17.2. $C_{17}H_{20}N_6Cl_2 \cdot 2HCl$ requires C, 50.2; H, 6.4; N, 17.2; Cl, 17.5%) (4067).

4-*p*-Chloroanilino-6- δ -diethylamino- α -methylbutylamino-2:5-dimethylpyrimidine (IV; R = Cl, R' = R'' = Me, R''' = CHMe $\cdot[CH_2]_3 \cdot NEt_3$).—The condensate (150–160° for 6 hours) of 4-chloro-6- δ -diethylamino- α -methylbutylamino-2:5-dimethylpyrimidine (14.93 g.) and *p*-chloroaniline (8.2 g.) was dissolved in dilute hydrochloric acid, made alkaline with sodium hydroxide, and then extracted with chloroform. Evaporation of the dried chloroform extract and distillation of the residue gave the base (9.4 g.) as a colourless highly viscous oil, b. p. 208°/0.55 mm. (Found: C, 64.5; H, 7.8; Cl, 9.5. $C_{21}H_{28}N_6Cl$ requires C, 64.7; H, 8.2; Cl, 9.1%) (3988). No solid salt could be isolated.

4-*p*-Bromoanilino-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine (IV; R = Br, R' = R'' = Me, R''' = $[CH_2]_2 \cdot NEt_3$).—4-Chloro-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine (10.26 g.) was mixed with *p*-bromoaniline hydrochloride (6.9 g.), a few drops of hydrochloric acid were added, and the whole was heated at 150–160° for 6 hours. The melt, originally fluid, was completely solid after 2.5 hours. Crystallisation from alcohol-ethyl acetate gave the dihydrochloride as colourless thick prisms, m. p. 265–266° (Found: C, 46.3; H, 6.4. $C_{18}H_{22}N_6Br_2 \cdot 2HCl$ requires C, 46.45; H, 6.0%).

4-Chloro-6-*p*-anisidino-2:5-dimethylpyrimidine (V; R = Cl, R' = R'' = Me).—(a) 4:6-Dichloro-2:5-dimethylpyrimidine (8.85 g.), *p*-anisidine (6.15 g.), water (40 c.c.), acetone (20 c.c.), and 10*N*-hydrochloric acid (1 c.c.) were refluxed for 3 hours. The mixture was diluted with water and made alkaline with ammonia. The filtered product was dissolved in 2-ethoxyethanol, and the solution made alkaline by the addition of a little ammonia and then poured into water. The precipitated solid was collected, washed with water, and dried. Crystallised from *n*-propanol, the base (9.5 g.) had m. p. 201° (Found: C, 58.8; H, 5.0; N, 15.8; Cl, 13.1. $C_{15}H_{14}ON_3Cl$ requires C, 59.2; H, 5.3; N, 15.9; Cl, 13.5%).

(b) 4:6-Dichloro-2:5-dimethylpyrimidine (5.31 g.), *p*-anisidine (4.5 g.), glacial acetic acid (30 c.c.), and 10*N*-hydrochloric acid (0.2 c.c.) were stirred at 40–45° for 20 hours. Sodium acetate (4 g.) was then added and the solution diluted with water (300 c.c.). On standing, the product gradually separated and was filtered off, washed with water, and dried. Crystallisation from benzene gave 4-chloro-6-*p*-anisidino-2:5-dimethylpyrimidine (6.4 g.) as colourless needles, m. p. and mixed m. p. 201° (Found: Cl, 13.4%).

4-*p*-Anisidino-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine (IV; R = OMe, R' = R'' = Me, R''' = $[CH_2]_2 \cdot NEt_3$).—The above chloropyrimidine (10 g.), β -diethylaminoethylamine (14 g.), and a crystal of potassium iodide were heated at 150–160° for 6 hours with stirring. The resulting reaction mixture was worked up as described previously for the corresponding *p*-chloroanilino-compound and gave the base (8.9 g.) as a colourless viscous oil, b. p. 203°/0.5 mm. (Found: C, 67.0; H, 9.3; N, 19.8. $C_{19}H_{24}ON_6$ requires C, 66.5; H, 8.5; N, 20.4%). The dihydrochloride crystallised from alcohol-ethyl acetate in clusters of colourless prisms, m. p. 254–255° (Found: C, 52.5; H, 7.7; N, 16.1; Cl, 16.9. $C_{19}H_{24}ON_6 \cdot 2HCl \cdot H_2O$ requires C, 52.5; H, 7.6; N, 16.1; Cl, 16.4%) (3962).

4-Chloro-6-*p*-nitroanilino-2:5-dimethylpyrimidine (V; R = NO₂, R' = R'' = Me).—4:6-Dichloro-2:5-dimethylpyrimidine (5.22 g.), *p*-nitroaniline (4.55 g.), acetic acid (50 c.c.), and a crystal of potassium iodide were heated at 55–60° for 18 hours. Sodium acetate (3 g.) was then added and the solution diluted with water (500 c.c.). The precipitated solid was filtered off, washed with water, and dried. Crystallised from butanol, the base formed yellow prisms (yield, 5.2 g.), m. p. 208–210° (Found: Cl, 12.9; $C_{15}H_{11}O_2N_3Cl$ requires Cl, 12.7%).

4-*p*-Nitroanilino-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine (IV; R = NO₂, R' = R'' = Me, R''' = $[CH_2]_2 \cdot NEt_3$).—(a) An intimate mixture of 4-chloro-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine (1.0 g.) and *p*-nitroaniline hydrochloride (0.68 g.) was heated at 150–160° for 6 hours with stirring in the initial stages. The cold melt was dissolved in hydrochloric acid, and the solution made alkaline with sodium hydroxide and extracted with chloroform. The chloroform solution was then extracted several times with 5% acetic acid and the combined acetic acid extracts were added to excess of sodium hydroxide. The precipitated oil was taken up in chloroform, and the solution dried and evaporated. Crystallisation of the residue from light petroleum (b. p. 80–100°) gave the base as thick yellow laminae, m. p. 104–106° (Found: C, 60.4; H, 7.3; N, 23.1. $C_{18}H_{22}O_2N_6$ requires C, 60.3; H, 7.3; N, 23.5%).

(b) 4-Chloro-6-*p*-nitroanilino-5:6-dimethylpyrimidine (1.8 g.), β -diethylaminoethylamine (1.8 g.),

and a trace of potassium iodide were heated at 155–165° for 5 hours and the mixture was worked up in the same way as in (a) to give the base (1.8 g.) which was converted into its *dihydrochloride*. This crystallised from alcohol-ethyl acetate in yellowish rectangular prisms, m. p. 254–256° (Found : C, 50.1; H, 6.5; N, 19.4. $C_{11}H_{10}O_2N_2 \cdot 2HCl$ requires C, 50.1; H, 6.5; N, 19.5%) (4188).

4 : 6-Dichloro-2-methyl-5-ethylpyrimidine.—4 : 6-Dihydroxy-2-methyl-5-ethylpyrimidine (30 g.) (Ferris and Ronzio, *J. Amer. Chem. Soc.*, 1940, **62**, 606) and phosphoryl chloride (110 c.c.) were refluxed for 2 hours and the bulk of the excess of phosphoryl chloride was then removed under diminished pressure. The residue was poured on ice (200 g.), the product extracted with benzene, and the solution dried (Na_2SO_4). The benzene was then removed by distillation through a short fractionating column and the residue distilled giving 4 : 6-dichloro-2-methyl-5-ethylpyrimidine as a colourless oil, b. p. 212–214° (Found : Cl, 37.2. $C_7H_8N_2Cl_2$ requires Cl, 37.2%).

4-Chloro-6-hydroxy-2-methyl-5-ethylpyrimidine (VI; R = Et).—4 : 6-Dichloro-2-methyl-5-ethylpyrimidine (25 g.), water (250 c.c.), and hydrochloric acid (100 c.c.) were boiled under reflux for 2.5 hours. The resulting clear solution was cooled, made alkaline with ammonia, and then acidified with acetic acid. Next day the product was filtered off and purified by dissolution in dilute sodium hydroxide and reprecipitation with acetic acid. The dried base crystallised from alcohol in colourless elongated prisms (yield, 19.2 g.), m. p. 209° (Found : C, 49.0; H, 5.0; N, 16.4. $C_7H_8ON_2Cl$ requires C, 48.7; H, 5.2; N, 16.2%).

4-p-Chloroanilino-6-hydroxy-2-methyl-5-ethylpyrimidine (VII; R = Cl, R' = Et).—4-Chloro-6-hydroxy-2-methyl-5-ethylpyrimidine (8.63 g.), *p*-chloroaniline (9.6 g.), and hydrochloric acid (0.5 c.c.) were mixed and heated at 160–170° for 8 hours. After cooling, the melt was dissolved in warm aqueous sodium hydroxide, and the solution treated with decolorising carbon and filtered. Addition of acetic acid to the filtrate gave the product which was filtered off, digested with aqueous ammonia, collected, and dried. 4-p-Chloroanilino-6-hydroxy-2-methyl-5-ethylpyrimidine crystallised from 2-ethoxyethanol in colourless needles (yield, 8.1 g.), m. p. 275° (Found : C, 59.0; H, 5.9; N, 16.1. $C_{13}H_{14}ON_2Cl$ requires C, 59.2; H, 6.1; N, 15.9%).

4-Chloro-6-*p*-chloroanilino-2-methyl-5-ethylpyrimidine (V; R = Cl, R' = Et, R'' = Me).—(a) 4 : 6-Dichloro-2-methyl-5-ethylpyrimidine (5.73 g.) and *p*-chloroaniline (4.3 g.) were dissolved in acetic acid (30 c.c.), a crystal of potassium iodide was added, and the solution was stirred at 35–45° for 20 hours. Sodium acetate (3 g.) was then added and the solution drowned into water to precipitate the base which was filtered off, dried, and crystallised, first from benzene-light petroleum (b. p. 60–80°) and then from dilute alcohol; long colourless rectangular prisms, m. p. 166° (Found : C, 55.6; H, 4.4; N, 14.5; Cl, 25.2. $C_{13}H_{13}N_2Cl_2$ requires C, 55.3; H, 4.6; N, 15.0; Cl, 25.2%).

(b) 4-*p*-Chloroanilino-6-hydroxy-2-methyl-5-ethylpyrimidine (8.9 g.) and phosphoryl chloride (45 c.c.) were refluxed for 1½ hours, and the clear solution was cooled and poured on ice. After being stirred for ½ hour the solution was made alkaline with sodium hydroxide and the precipitated product filtered off, washed with water, and dried. On boiling it with benzene a small amount of unchanged hydroxy-compound remained undissolved. This was removed by filtration and the benzene evaporated. Crystallisation of the residue from dilute alcohol gave the same compound as in (a), m. p. and mixed m. p. 166° (Found : C, 55.6; H, 4.4; N, 14.8%).

4- γ -Diethylaminopropylamino-6-hydroxy-2-methyl-5-ethylpyrimidine (VIII; R = Et, R' = $[CH_2]_3 \cdot NEt_2$).—4-Chloro-6-hydroxy-2-methyl-5-ethylpyrimidine (34.5 g.) and γ -diethylaminopropylamine (26 g.) were heated at 150–160° for 8 hours, with stirring until the melt solidified. A small sample of the resulting hydrochloride of 4- γ -diethylaminopropylamino-6-hydroxy-2-methyl-5-ethylpyrimidine on treatment with picric acid in alcohol gave the *dipicrate* which crystallised from 2-ethoxyethanol-alcohol in flat yellow prisms, m. p. 188° (Found : C, 42.9; H, 4.7; N, 19.4. $C_{14}H_{18}ON_4 \cdot 2C_6H_3O_7N_3$ requires C, 43.1; H, 4.4; N, 19.3%).

4-Chloro-6- γ -diethylaminopropylamino-2-methyl-5-ethylpyrimidine (IX; R = Et, R' = Me, R'' = $[CH_2]_3 \cdot NEt_2$).—The above hydrochloride (59.5 g.) was refluxed with phosphoryl chloride (225 c.c.) during 15 hours, and the reaction mixture worked up as described previously for this type of compound, giving the *chloropyrimidine* as a colourless oil, b. p. 142°/0.095 mm. (Found : N, 19.1; Cl, 12.1. $C_{14}H_{18}N_4Cl$ requires N, 19.7; Cl, 12.5%). It gave a *dipicrate* which crystallised from alcohol in yellow tables, m. p. 147–148° (Found : C, 42.0; H, 4.2; N, 18.8. $C_{14}H_{18}N_4Cl \cdot 2C_6H_3O_7N_3$ requires C, 42.0; H, 4.2; N, 18.85%).

4-*p*-Chloroanilino-6- β -diethylaminoethylamino-2-methyl-5-ethylpyrimidine (IV; R = Cl, R' = Et, R'' = Me, R''' = $[CH_2]_3 \cdot NMe_2$).—4-Chloro-6-*p*-chloroanilino-2-methyl-5-ethylpyrimidine (2.0 g.), β -diethylaminoethylamine (2.0 g.), and a crystal of potassium iodide were stirred and heated at 140–150° for 6 hours. The resulting mixture was dissolved in dilute hydrochloric acid and the solution made alkaline with sodium hydroxide. The precipitate was separated by decantation and dissolved in 5% acetic acid, and the solution was filtered. On addition of sodium hydroxide to the filtrate, the base was obtained as an oil which was extracted with benzene, and the extract was dried and evaporated. The residual oily base gave a *dihydrochloride* which crystallised from alcohol-ethyl acetate in colourless thick prisms, m. p. 268–270° (decomp.) (Found : C, 52.3; H, 6.8; N, 16.0; Cl', 16.3. $C_{18}H_{22}N_6Cl_2 \cdot 2HCl$ requires C, 52.5; H, 6.9; N, 16.1; Cl', 16.3%) (4046).

4-*p*-Chloroanilino-6- γ -dimethylaminopropylamino-2-methyl-5-ethylpyrimidine (IV; R = Cl, R' = Et, R'' = Me, R''' = $[CH_2]_3 \cdot NMe_2$).—Obtained similarly from 4-chloro-6-*p*-chloroanilino-2-methyl-5-ethylpyrimidine and γ -dimethylaminopropylamine, this gave a *dipicrate* which crystallised from alcohol in thick yellow laminæ, m. p. 171–173° (Found : C, 45.1; H, 4.5. $C_{18}H_{22}N_6Cl_2 \cdot 2C_6H_3O_7N_3$ requires C, 44.7; H, 4.0%), and a *dihydrochloride* which crystallised from alcohol-ethyl acetate in colourless flat prisms, m. p. 278–279° (decomp.) (Found : C, 47.7; H, 7.3; N, 15.1; Cl', 15.3. $C_{18}H_{22}N_6Cl_2 \cdot 2HCl \cdot 2H_2O$ requires C, 47.3; H, 7.0; N, 15.3; Cl', 15.6%) (4017).

4-*p*-Chloroanilino-6- γ -diethylaminopropylamino-2-methyl-5-ethylpyrimidine (IV; R = Cl, R' = Et, R'' = Me, R''' = $[CH_2]_3 \cdot NEt_2$).—4-Chloro-6- γ -diethylaminopropylamino-2-methyl-5-ethylpyrimidine (8.35 g.), *p*-chloroaniline (4.8 g.), and a few drops of hydrochloric acid were heated at 150–160° for 6 hours with stirring. The melt (cooled) was dissolved out with hydrochloric acid and the solution

made alkaline with sodium hydroxide. The liberated oil was extracted with benzene, and the extract dried and evaporated. Distillation of the remaining oil gave 4-*p*-chloroanilino-6- γ -diethylaminopropylamino-2-methyl-5-ethylpyrimidine (6.3 g.), b. p. 210°/0.065 mm. (Found: C, 63.5; H, 8.0. $C_{26}H_{30}N_8Cl$ requires C, 63.9; H, 8.0%), which formed a *dihydrochloride*, colourless prisms from alcohol-ethyl acetate, m. p. 162° (Found: C, 50.9; H, 7.1; N, 14.9; Cl, 14.8. $C_{26}H_{30}N_8Cl_2 \cdot 2HCl \cdot H_2O$ requires C, 51.4; H, 7.3; N, 15.0; Cl, 15.2%).

4-*p*-Anisidino-6-hydroxy-2-methyl-5-ethylpyrimidine (VII; R = OMe, R' = Et).—4-Chloro-6-hydroxy-2-methyl-5-ethylpyrimidine (17.25 g.), *p*-anisidine (12.3 g.), and hydrochloric acid (1 c.c.) were heated at 160–170° for 3 hours. The mixture was dissolved in dilute sodium hydroxide solution, and the solution treated with decolorising carbon and filtered. Acidification of the filtrate with acetic acid gave a product which was freed from a small amount of unchanged 4-chloro-6-hydroxy-2-methyl-5-ethylpyrimidine by stirring with 10% aqueous ammonia for 3 hours and filtering. After being washed with water and dried, the base crystallised from alcohol in colourless thick prisms, m. p. 199–200° (Found: C, 65.0; H, 6.6; N, 16.3. $C_{14}H_{11}O_2N_3$ requires C, 64.9; H, 6.6; N, 16.2%).

4-Chloro-6-*p*-anisidino-2-methyl-5-ethylpyrimidine (V; R = OMe, R' = Et, R'' = Me).—(a) 4:6-Dichloro-2-methyl-5-ethylpyrimidine (5.73 g.) and *p*-anisidine (4.1 g.) were kept in acetic acid (30 c.c.), with the addition of a crystal of potassium iodide, at 40–45° for 20 hours. After addition of sodium acetate (3 g.) the solution was drowned into water (300 c.c.), and the precipitated product filtered off, washed with water, and crystallised from dilute alcohol; colourless elongated prisms, m. p. 157° (Found: C, 60.6; H, 5.7; N, 15.2. $C_{14}H_{11}ON_3Cl$ requires C, 60.5; H, 5.8; N, 15.1%).

(b) 4-*p*-Anisidino-6-hydroxy-2-methyl-5-ethylpyrimidine (11.9 g.) and phosphoryl chloride (60 c.c.) were boiled under reflux for 1½ hours and the clear solution poured on ice. Addition of ammonia precipitated the product which was purified by crystallisation from dilute alcohol. It then had m. p. 157° either alone or in admixture with material made by method (a) (Found: C, 60.1; H, 5.4%).

4-*p*-Anisidino-6- β -diethylaminoethylamino-2-methyl-5-ethylpyrimidine (IV; R = OMe, R' = Et, R'' = Me, R''' = $[CH_2]_2 \cdot NEt_2$).—4-Chloro-6-*p*-anisidino-2-methyl-5-ethylpyrimidine (2.75 g.) and β -diethylaminoethylamine (2.5 g.) were heated at 155–165° for 8 hours and the mixture worked up as in the case of the corresponding *p*-chloroanilino-compound, giving the *dihydrochloride* as colourless laminae from alcohol-ethyl acetate, m. p. 250–251° (decomp.) (Found: C, 55.5; H, 7.5; N, 15.9; Cl, 16.3. $C_{26}H_{31}ON_8 \cdot 2HCl$ requires C, 55.8; H, 7.7; N, 16.3; Cl, 16.5%) (4048).

4-*p*-Anisidino-6- γ -dimethylaminopropylamino-2-methyl-5-ethylpyrimidine (IV; R = OMe, R' = Et, R'' = Me, R''' = $[CH_2]_3 \cdot NMe_2$).—4-Chloro-6-*p*-anisidino-2-methyl-5-ethylpyrimidine (2.75 g.) and γ -dimethylaminopropylamine (2.5 g.) were heated, with the addition of a trace of potassium iodide, at 150–160° for 8 hours with stirring. The melt was dissolved in dilute hydrochloric acid and the solution poured into excess of sodium hydroxide solution. The precipitated product was collected and purified by dissolution in 5% acetic acid and reprecipitation with sodium hydroxide. The base, isolated by extraction with benzene, crystallised from light petroleum (b. p. 80–100°) in colourless needles, m. p. 106–107° (Found: C, 66.2; H, 7.8; N, 20.3. $C_{19}H_{20}ON_3$ requires C, 66.5; H, 8.5; N, 20.4%) (4069).

4:6-Dichloro-5-phenyl-2-methylpyrimidine.—4:6-Dihydroxy-5-phenyl-2-methylpyrimidine (40 g.) (Dox and Yoder, *J. Amer. Chem. Soc.*, 1922, **44**, 361) and phosphoryl chloride (140 c.c.) were boiled under reflux for 2 hours. The excess of phosphoryl chloride was then removed under reduced pressure and the residue poured on a mixture of ice and water (300 g.). After ¼ hour's stirring, the product which had separated was filtered off, washed acid-free with water, and crystallised from alcohol; colourless plates, m. p. 160° (Found: C, 55.2; H, 3.1; Cl, 29.1. $C_{11}H_8N_2Cl_2$ requires C, 55.2; H, 3.35; Cl, 29.7%) (4070).

4-Chloro-6-*p*-chloroanilino-5-phenyl-2-methylpyrimidine (V; R = Cl, R' = Ph, R'' = Me).—4:6-Dichloro-5-phenyl-2-methylpyrimidine (11.95 g.) and *p*-chloroaniline (6.4 g.) were ground together, acetic acid (3 g.) was added, and the mixture was heated at 110–115° for 1 hour. The cooled melt was dissolved in alcohol, and the solution made alkaline with ammonia and poured into water. The precipitated base was filtered off, washed with water, and dried. Crystallised from light petroleum (b. p. >120°), it formed colourless prisms (9.5 g.), m. p. 155–156° (Found: C, 62.1; H, 4.1; N, 12.8; Cl, 21.2. $C_{17}H_{13}N_3Cl_2$ requires C, 61.8; H, 3.9; N, 12.7; Cl, 21.5%) (4071).

4-*p*-Chloroanilino-6- β -diethylaminoethylamino-5-phenyl-2-methylpyrimidine (IV; R = Cl, R' = Ph, R'' = Me, R''' = $[CH_2]_2 \cdot NEt_2$).—The above chloropyrimidine (12.0 g.), β -diethylaminoethylamine (12.0 g.), and a crystal of potassium iodide were heated at 150–160° for 6 hours with stirring and then worked up to give the pyrimidine which crystallised from light petroleum (b. p. 40–60°) in colourless laminae, m. p. 88–89° (Found: C, 67.0; H, 7.1; N, 17.5. $C_{23}H_{28}N_6Cl$ requires C, 67.4; H, 6.8; N, 17.1%) (4072).

4-*p*-Chloroanilino-6- γ -diethylaminopropylamino-5-phenyl-2-methylpyrimidine (IV; R = Cl, R' = Ph, R'' = Me, R''' = $[CH_2]_3 \cdot NEt_2$).—The above chloropyrimidine (12.0 g.) was prepared in a similar manner using γ -diethylaminopropylamine in place of β -diethylaminoethylamine, crystallised from light petroleum (b. p. 40–60°) in colourless thick rectangular prisms, m. p. 77–78° (Found: C, 67.7; H, 6.8; N, 16.7. $C_{24}H_{30}N_6Cl$ requires C, 68.0; H, 7.1; N, 16.5%). A crystalline dihydrochloride could not be obtained either from this or the preceding compound.

4-Chloro-2-amino-6-*p*-chloroanilino-5-phenylpyrimidine (V; R = Cl, R' = H, R'' = NH_2).—(a) 4:6-Dichloro-2-aminopyrimidine (12.3 g.) and *p*-chloroaniline (9.6 g.) were ground together, acetic acid (9.0 g.) was added, and the mixture was heated to 110°. After a few minutes at this temperature a vigorous reaction occurred, and the reaction mixture which had previously become fluid and homogeneous suddenly set solid. The cooled and ground melt was boiled with alcohol (150 c.c.) containing ammonia for 1½ hours, then diluted with water, and the product collected and dried. Crystallised from ethyl acetate it formed colourless prisms (yield, 11.6 g.), m. p. 242–243° (Found: C, 47.1; H, 3.2; N, 21.9; Cl, 28.1. $C_{16}H_8N_4Cl_2$ requires C, 47.1; H, 3.1; N, 22.0; Cl, 27.7%). Addition of hydrochloric acid to its alcoholic solution gave a *hydrochloride* as colourless needles, m. p. 252–254° (Found: N, 18.2; Cl, 33.6. $C_{16}H_8N_4Cl_2 \cdot HCl \cdot H_2O$ requires N, 18.1; Cl, 34.4%).

(b) 4:6-Dichloro-2-aminopyrimidine (8.2 g.), *p*-chloroaniline (6.3 g.), water (40 c.c.), acetone (10 c.c.),

and 10*N*-hydrochloric acid (0.5 c.c.) were boiled under reflux for 2 hours. After cooling, the product was filtered off, washed with water, and dissolved in boiling 2-ethoxyethanol with the addition of ammonia to give an alkaline reaction. After dilution with water the precipitated product was filtered off, washed with water, dried, and crystallised from ethyl acetate; m. p. 241—242° either alone or admixed with the product from (a) above (yield, 6.5 g.).

4-Chloro-2-amino-6-*p*-anisidinopyrimidine (V; R = OMe, R' = H, R'' = NH₂).—To an intimate mixture of 4 : 6-dichloro-2-aminopyrimidine (12.3 g.) and *p*-anisidine (9.2 g.), acetic acid (4.5 g.) was added and the mixture heated to 110°; a vigorous reaction then took place. After $\frac{1}{2}$ hour at 110°, the melt was cooled, ground, and stirred with dilute ammonia for 2 hours. The resulting base was filtered off, washed with water, and crystallised from alcohol, giving colourless prisms (8.9 g.), m. p. 224—225° (Found: C, 53.1; H, 4.6; N, 22.1. C₁₁H₁₁ON₄Cl requires C, 52.7; H, 4.4; N, 22.35%). The hydrochloride had m. p. 236° (decomp.) (Found: N, 19.3; Cl, 24.1. C₁₁H₁₁ON₄Cl.HCl requires N, 19.5; Cl, 24.7%).

4-Chloro-2-amino-6-*p*-toluidinopyrimidine (V; R = Me, R' = H, R'' = NH₂), prepared similarly using *p*-toluidine in place of *p*-anisidine, crystallised from alcohol in colourless laminae, m. p. 239—241° (Found: C, 56.1; H, 4.7; N, 23.8. C₁₁H₁₁N₄Cl requires C, 56.3; H, 4.7; N, 23.9%). It formed a hydrochloride, m. p. 259—260° (decomp.) (Found: N, 20.3; Cl, 26.4. C₁₁H₁₁N₄Cl.HCl requires N, 20.3; Cl, 26.4%).

2-Amino-4-*p*-chloroanilino-6- β -diethylaminoethylaminopyrimidine (IV; R = Cl, R' = H, R'' = NH₂, R''' = [CH₂]₂.NEt₂).—(a) 4-Chloro-2-amino-6-*p*-chloroanilinopyrimidine hydrochloride (9.7 g.) and β -diethylaminoethylamine (4.84 g.) were heated at 150—160° for 5 hours, and the mixture was cooled and dissolved in water. To the solution sodium hydroxide was added, and the precipitated product was extracted with chloroform. The chloroform solution was shaken several times with 5% acetic acid and the acid extracts were combined, made alkaline with sodium hydroxide, and extracted with chloroform. The dried chloroform solution, on evaporation, gave the base which crystallised from benzene in colourless laminae (8 g.), m. p. 135° (Found: C, 57.4; H, 7.0; N, 24.7. C₁₈H₂₃N₅Cl requires C, 57.4; H, 6.9; N, 25.1%) (3861).

(b) 4-Chloro-2-amino-6- β -diethylaminoethylaminopyrimidine (6.1 g.) (see below) and *p*-chloroaniline hydrochloride (4.1 g.) were mixed and heated in an oil-bath at 170—180° for 6 hours. The resulting melt was dissolved in warm dilute hydrochloric acid and then worked up as in (a) to give 2-amino-4-*p*-chloroanilino-6- β -diethylaminoethylaminopyrimidine, m. p. and mixed m. p. 134—135°.

By method (a) above a number of other 2-amino-4-arylamino-6-dialkylaminoalkylaminopyrimidines were prepared. Details of these are given in Table I.

4-Chloro-2-amino-6-*p*-chloroanilino-5-ethylpyrimidine (V; R = Cl, R' = Et, R'' = NH₂).—4 : 6-Dichloro-2-amino-5-ethylpyrimidine (19.2 g.) (v. Merckat, *Ber.*, 1919, 52, 869) and *p*-chloroaniline (12.75 g.) were ground together, acetic acid (6 g.) was added, and the mixture was heated at 100—110° for $\frac{1}{2}$ hour with stirring. A homogeneous melt was obtained which suddenly solidified after about $\frac{1}{2}$ hour. The cooled and ground melt was dissolved in boiling alcohol with the addition of ammonia to give an alkaline reaction, and the solution poured into water. The precipitated product was filtered off and dried. By crystallisation from benzene it was obtained as colourless tables (19.25 g.), m. p. 158—160° (Found: C, 51.2; H, 4.2; N, 19.4. C₁₂H₁₂N₄Cl₂ requires C, 50.9; H, 4.2; N, 19.8%). The hydrochloride crystallised from alcohol containing a little hydrochloric acid in long colourless prisms, m. p. >290° (Found: C, 45.6; H, 4.5; N, 17.6. C₁₂H₁₂N₄Cl₂.HCl requires C, 45.1; H, 4.1; N, 17.5%).

4-Chloro-2-amino-6-*p*-cyanoanilino-5-ethylpyrimidine (V; R = CN, R' = Et, R'' = NH₂).—4 : 6-Dichloro-2-amino-5-ethylpyrimidine (12.8 g.) and *p*-cyanoaniline (7.86 g.) were mixed, and acetic acid (4 g.) was added. After being heated for some time at 120° the fluid mixture suddenly solidified. Heating at 120—130° was continued for 1 hour, and the melt then dissolved in 2-ethoxyethanol, ammonia added, and the solution poured into water. The dried precipitated product crystallised from butanol in colourless rhombs (10 g.), m. p. 230—232° (Found: C, 57.0; H, 4.1; N, 25.1. C₁₃H₁₂N₅Cl requires C, 57.0; H, 4.4; N, 25.6%).

4 : 6-Dichloro-2-amino-5-phenylpyrimidine.—Guanidine nitrate (24.4 g.) was added to a hot solution of sodium (9.2 g.) in methanol (250 c.c.) and, after $\frac{1}{2}$ hour's refluxing, ethyl phenylmalonate (47.2 g.) was added. The mixture was boiled under reflux for 3 hours and then allowed to cool. The solid was collected and the filtrate evaporated; the residue and the solid were combined and dissolved in warm water, and the solution was treated with decolourising carbon and filtered. The filtrate was acidified with acetic acid at 80°, and the product collected, washed with water, and dried (25.6 g.). This 2-amino-4 : 6-dihydroxy-5-phenylpyrimidine (20 g.) and phosphoryl chloride (90 c.c.) were boiled under reflux for 3 hours, and the resulting clear solution was poured on ice (600 g.) with stirring. After 2 hours' stirring, ammonia was gradually added until the mixture was neutral. The solid product was filtered off, washed with water, and dried. Purification by vacuum sublimation at 160—170°/14 mm. followed by crystallisation from alcohol, gave 4 : 6-dichloro-2-amino-5-phenylpyrimidine as colourless plates, m. p. 221—222° (Found: C, 50.3; H, 2.9; N, 17.3. C₁₀H₇N₃Cl₂ requires C, 50.0; H, 2.9; N, 17.5%).

4-Chloro-2-amino-6-*p*-chloroanilino-5-phenylpyrimidine (V; R = Cl, R' = Ph, R'' = NH₂).—Acetic acid (3 g.) was added to an intimate mixture of 4 : 6-dichloro-2-amino-5-phenylpyrimidine (12.0 g.) and *p*-chloroaniline (6.45 g.) and the whole heated at 120—130° for 1.5 hours. The mixture gradually melted and then resolidified. After being ground and stirred with dilute ammonia, the solid product was dissolved in 2-ethoxyethanol, ammonia added to alkalinity, and the solution diluted with water. The crystalline pyrimidine which separated on standing was filtered off, dried, and crystallised from butanol; colourless laminae, m. p. 228—229° (Found: C, 58.0; H, 3.6; N, 16.9%).

2-Amino-4-arylamino-6-dialkylaminoalkylamino-5-substituted Pyrimidines.—The appropriate 4-chloro-2-amino-6-arylamino-5-substituted pyrimidine was heated with excess of dialkylaminoalkylamine and a trace of potassium iodide for 6 hours at 160—165°. The resulting mixture was dissolved in dilute hydrochloric acid and the solution filtered, if necessary, from insoluble material. The filtrate was added to excess

of sodium hydroxide and the precipitated product either filtered off or (if liquid) extracted with chloroform. In either case purification was effected by extraction with 5% acetic acid and reprecipitation with sodium hydroxide. The precipitated product was collected and dried, or extracted with chloroform and the dried extract evaporated, and then crystallised. The compounds prepared are given in Table II.

4-Chloro-2-amino-6-aminoalkylaminopyrimidines.—The requisite 4 : 6-dichloro-2-aminopyrimidine was mixed with the aminoalkylamine (1 mol.) and acetic acid (1 mol.), and heated at 100–110° (115–120° in the case of the 5-phenyl compounds) for 3 hours. The cooled mixture was lixiviated with dilute hydrochloric acid and the solution filtered from unchanged pyrimidine. Addition of sodium hydroxide to the filtrate precipitated the product which was isolated either by filtration or by extraction with ether and then purified by dissolution in 5% acetic acid and reprecipitation with sodium hydroxide. If solid, the product was filtered off and dried; otherwise, it was extracted with ether, and the solution dried and evaporated. The product was then crystallised. Details of the compounds prepared are given in Table III.

[Received, December 16th, 1946.]

252. γ -6-Methoxy-1 : 2 : 3 : 4-tetrahydro-1-naphthylidenecrotonic Acid.

By WALTER C. J. ROSS.

γ -6-Methoxy-1 : 2 : 3 : 4-tetrahydro-1-naphthylidenecrotonic acid has been prepared and its structure elucidated by oxidative degradation and by measurement of its ultra-violet absorption spectrum. The acid can be used in a convenient new synthesis of 1-keto-7-methoxy-1 : 2 : 3 : 4-tetrahydrophenanthrene.

It has been shown that γ -bromocrotonic esters can be used in the Reformatsky reaction in the same way as α -bromo-esters (Fuson, Arnold, and Cooke, *J. Amer. Chem. Soc.*, 1938, **60**, 2272; Ziegler, Schumann, and Winkelmann, *Annalen*, 1942, **551**, 120) and this method has recently been applied by Cook and Schoental (*J.*, 1945, 288), who suggested the formula (I) for the compound obtained from 1-keto-1 : 2 : 3 : 4-tetrahydrophenanthrene.

The reaction has now been applied to 6-methoxy-1-tetralone, an acid, $C_{15}H_{16}O_3$, m. p. 189–190°, being obtained after the hydrolysis of the ester first formed. By analogy it was regarded as having structure (II). However, the acid exhibits absorption maxima (in chloroform solution) at 2490 Å. and 3480 Å., $\epsilon = 10,300$ and 30,000 respectively. These figures are in much better agreement with a structure such as (III), since this contains a more extended system of conjugation, though the wave-length of the primary maximum is rather higher than would be expected for even this system—this fact could possibly be ascribed to the “exocyclic” of one of the double bonds. Structure (III) is also supported by the fact that when the acid is oxidised by alkaline potassium permanganate an 80% yield of 6-methoxy-1-tetralone is obtained. Rearrangement of the double bonds is very unlikely under the mild conditions of the oxidation and so the new acid is regarded as γ -6-methoxy-1 : 2 : 3 : 4-tetrahydro-1-naphthylidenecrotonic acid (III).

When the acid is heated at 280–300° with palladium-black, a 55% yield of γ -6-methoxy-1-naphthylbutyric acid is obtained. If the methyl ester of (III) is similarly heated and the product is hydrolysed, an almost quantitative yield of the naphthalenic acid is obtained. Cyclisation of the acid thus formed yields 1-keto-7-methoxy-1 : 2 : 3 : 4-tetrahydrophenanthrene (Bachmann, Cole, and Wilds, *J. Amer. Chem. Soc.*, 1940, **62**, 284) which is a useful intermediate in the production of synthetic hormones, particularly those of the doisyolic acid series (Heer, Billeter, and Miescher, *Helv. Chim. Acta*, 1945, **28**, 1342); the method now described is a very convenient one for the preparation of this ketone.

Reduction of the acid (III) in acetic acid–ethanol solution using a palladium catalyst, or in aqueous alkaline solution using a Raney nickel catalyst, gives a high yield of γ -6-methoxy-1 : 2 : 3 : 4-tetrahydro-1-naphthylbutyric acid (IV), and when heated with sulphur at 200° this is converted into γ -6-methoxy-1-naphthylbutyric acid (compare Haberland, *Ber.*, 1936 **69**, 1380). These reactions provide an alternative route for the conversion of the acid (III) into 1-keto-7-methoxy-1 : 2 : 3 : 4-tetrahydrophenanthrene.

EXPERIMENTAL.

(M. ps. were determined in sealed capillaries and are uncorrected.)

γ -6-Methoxy-1:2:3:4-tetrahydro-1-naphthylidenecrotonic Acid (III).—Zinc wool (35 g.) was placed in a large flask, dry benzene (400 c.c.) containing mercuric chloride (100 mg.) added, and the mixture warmed for 15 minutes. 6-Methoxy-1-tetralone (94 g.) was added and then ethyl γ -bromocrotonate (114 g., b. p. 80–85°/2 mm., prepared essentially by the method of Ziegler *et al.*, *Annalen*, 1942, 551, 80) was run in at such a rate that the reaction proceeded at a vigorous but controllable pace. The mixture was heated under reflux for a further hour after all the ester had been added, and by this time a deep red complex had separated and most of the zinc had dissolved. The mixture was cooled and decomposed by shaking it with 2N-hydrochloric acid (500 c.c.). The product was extracted with ether, and the extract was washed with water, evaporated, and heated under reflux for 2 hours with potassium hydroxide (50 g.) in methanol (500 c.c.) and water (100 c.c.). The mixture was diluted with water and extracted with ether—this extract contained unchanged ketone (50 g.)—and then the aqueous layer was acidified, a yellow precipitate of the unsaturated acid being formed. The solid (28 g.) was collected and recrystallised from acetone or methanol; it formed hard prisms, m. p. 189–190° (Found: C, 73.2; H, 6.8. $C_{15}H_{14}O_3$ requires C, 73.7; H, 6.6%).

The methyl ester was prepared by the action of an ethereal solution of diazomethane on the acid or by refluxing the acid (10 g.) with methanol (80 c.c.) containing acetyl chloride (10 c.c.) for one hour (compare Riegel and Moffat, *J. Amer. Chem. Soc.*, 1943, 65, 1971). In each case the crystalline residue obtained after evaporating off the solvents was recrystallised from methanol, giving lemon-yellow prismatic plates of the ester, m. p. 85–86° (Found: C, 74.2; H, 7.2. $C_{16}H_{16}O_3$ requires C, 74.4; H, 7.0%).

Oxidation of Acid (III).—The acid (2 g.) was dissolved in excess of 2N-sodium carbonate, and finely powdered potassium permanganate was added to the stirred solution until the supernatant liquid remained coloured. The product was extracted with ether, and the extract dried (Na_2SO_4) and evaporated. 6-Methoxy-1-tetralone (1.15 g., 80%), m. p. 78–79° (undepressed by admixture with an authentic specimen of m. p. 79°), was obtained.

γ -6-Methoxy-1-naphthylbutyric Acid.—The methyl ester of (III) (10 g.) was heated at 280–300° for 1 hour in a metal-bath with palladium-black (700 mg.). The product was dissolved in methanol (60 c.c.), potassium hydroxide (10 g. in 10 c.c. of water) added, and the mixture heated under reflux for 2 hours. The cooled solution was filtered and then acidified with dilute hydrochloric acid; the naphthalenic acid (9.7 g.), m. p. 149–151°, was thus precipitated (Cohen, Cook, and Hewett, *J.*, 1936, 52, give m. p. 150–151°).

Reduction of Acid (III).—(a) The acid (1.0 g.) was dissolved in ethanol (75 c.c.) and acetic acid (10 c.c.), and after addition of palladium-strontium carbonate (500 mg. containing 5% palladium) the solution was shaken in an atmosphere of hydrogen. Hydrogen was rapidly absorbed, and after $\frac{1}{2}$ hour the theoretical volume of gas (calculated for the reduction of two double bonds) had been taken up. The solvents were evaporated, and the oily residue was crystallised from light petroleum (b. p. 60–80°), giving the required acid, m. p. 76–78° (900 mg.) (Haberland, *loc. cit.*, gives m. p. 79°).

(b) The acid (2.5 g.) was dissolved in water (25 c.c.) containing sodium hydroxide (6 c.c. 2N), Raney nickel catalyst (1 g.) added, and the mixture shaken in an atmosphere of hydrogen. The theoretical volume of hydrogen was absorbed in 3 hours. After filtration, the solution was acidified, and the oily precipitate crystallised from light petroleum. In this way 2.1 g. of the required acid, m. p. 77°, were obtained.

When the acid prepared by either method was heated at 200° for 3 hours with $\frac{1}{2}$ its weight of sulphur, γ -6-methoxy-1-naphthylbutyric acid, m. p. 149–150°, was obtained.

The author's thanks are due to Professor J. W. Cook, F.R.S., for suggesting this method of preparing 1-keto-7-methoxy-1:2:3:4-tetrahydrophenanthrene, to Dr. E. A. Braude for measuring the absorption spectrum, and to Organon Laboratories Ltd. for permission to publish the results.

253. The Structure of Anhydrotetronic Acid.

By D. H. MARRIAN, P. B. RUSSELL, A. R. TODD, and W. S. WARING.

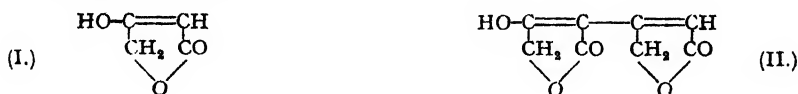

Anhydrotetronic acid, obtained by refluxing tetronic acid in aqueous solution, is shown by degradative studies to have structure (II).

IN the course of investigations in this laboratory on the hatching factor for the potato eelworm (*Heterodera rostochiensis* Wollenweber) produced by certain host species of *Solanaceae* it was observed that anhydrotetronic acid possessed the property of hatching eelworm cysts (Calam, Todd, and Waring, to be published elsewhere). Since this acid was at that time the only active synthetic substance known, it was a matter of considerable importance for further work that its precise structure should be ascertained, and the investigation described in this paper was accordingly carried out.

Anhydrotetronic acid was first described by Wolff and Schwabe (*Annalen*, 1896, 291, 251), who obtained it as colourless crystals containing one molecule of water of crystallisation by heat,

ing an aqueous solution of tetronic acid (I). The anhydrous acid, $C_6H_6O_5$, was monobasic and had m. p. 263° (decomp.). Later Wolff (*Annalen*, 1901, **315**, 162) showed that it contained in all probability a reactive methylene group, since with aliphatic and aromatic aldehydes it gave alkylidene- or arylidene-bisanhydrotetronic acids; analogous compounds are obtained from tetronic acid on similar treatment. No further examination of anhydrotetronic acid seems to have been made.

Anhydrotetronic acid, like tetronic acid, owes its acidic properties to an enolic hydroxyl group; it gives a maroon colour with ferric chloride and couples readily with diazonium compounds. On treatment with diazomethane it gives a neutral methyl ether giving no ferric reaction, and on bromination it yields a *mono-bromo-derivative*. It shows strong selective light absorption in the ultra-violet region, and hydrolytic titration at 100° with $N/100$ -sodium hydroxide shows only 20% of the uptake expected for one lactone group. Under optimum conditions anhydrotetronic acid is formed in a yield of only *ca.* 33% by heating aqueous solutions of tetronic acid, but when the water is replaced by aqueous morpholine reaction proceeds rapidly and the yield is almost quantitative. These facts suggest that anhydrotetronic acid has structure (II), but, especially since no analogous compound is obtained under similar conditions from either α - or γ -substituted tetronic acids, it was considered desirable to establish the validity of this structure by degradative methods.

Oxidation of anhydrotetronic acid with potassium permanganate gave oxalic acid, while fusion with potassium hydroxide yielded both oxalic and acetic acids. Refluxed with dilute sulphuric acid, anhydrotetronic acid evolved 1 mol. of carbon dioxide during 15 hours; the product, a resinous acid, gave a crystalline *p*-phenylphenacyl ester, but was not identified. Hydrogenation of anhydrotetronic acid in methanolic solution with a platinum catalyst proceeded rather slowly and ceased when about 2.5 mols. of hydrogen had been taken up. The product was not homogeneous and could be readily separated into neutral and acidic fractions. The acidic fraction was semi-solid, and no crystalline derivative could be prepared from it. It clearly contained an enolic hydroxyl group, since it gave a maroon ferric reaction and showed selective light absorption at 2330 \AA . (ϵ , 5000). Titration of the crude fraction gave an equivalent of 221, and hydrolytic titration caused a further uptake of alkali equivalent to 93% of that required for a second acid grouping. The failure to isolate any crystalline derivative from the material suggested that it was probably a mixture of acids; it was accordingly oxidised with potassium permanganate in the hope of obtaining identifiable fragments which would give some clue to its nature. Oxidation was at first rapid but slowed down later and was stopped when the equivalent of 6 atoms of oxygen had been used up. From the product, tricarballic acid (propane-1:2:3-tricarboxylic acid) (III) and homoparaconic acid (homopilosinic acid, butanolide-2-acetic acid) (IV) were isolated. The isolation of (IV) is significant, since it is clear that in its formation the portion of the anhydrotetronic acid molecule (and of the enolic reduced acid) containing the enolic hydroxyl group has been destroyed. The lactone ring of (IV) is derived from one of the tetronic acid residues present in the starting material, and it is evident that the β -carbon atom in this residue must have been joined to the α -position of the second (enolic) residue in anhydrotetronic acid.

The distilled neutral fraction from the hydrogenation of anhydrotetronic acid was stable to permanganate and showed no selective light absorption in the ultra-violet region. It was evidently a mixture, since it gave analytical values lying between those corresponding to $C_8H_{10}O_4$ and $C_8H_{14}O_5$, and hydrolytic titration gave an equivalent of 101. Treatment with hydrazine gave a mixture of isomeric dihydrazides, $C_8H_{14}O_4N_4$, which was separated into one pure *dihydrazide*, m. p. 155° , which was sparingly soluble in methanol, and a mixture of more soluble dihydrazides, m. p. 125 – 140° . Both the dihydrazide, m. p. 155° , and the isomer mixture were oxidised by periodate, 3 mols. of reagent being consumed in each case. Since model experiments showed that hydrazides are oxidised by periodate according to the equation $2R\cdot CO\cdot NH\cdot NH_2 + 2O = R\cdot CO\cdot NH\cdot NH\cdot COR + N_2 + 2H_2O$, it can be deduced that the dihydrazides obtained above contain one α -glycol grouping. From these facts it is concluded that the neutral fraction from the hydrogenation contained the methyl ester of a lactonic hydroxy-acid, $C_8H_{12}O_4$, and the corresponding dilactone in their various stereoisomeric modifications; treatment of such a mixture with hydrazine would obviously yield a mixture of stereo-

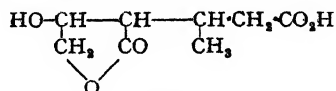

isomeric dihydrazides. It may further be inferred that the potential carboxyl groups of the two tetronic acid molecules involved in the formation of anhydrotetronic acid are still present in the latter compound, and that the ring which has been opened by hydrogenolysis to form the acid $C_6H_{12}O_4$ is not the one bearing the enolic hydroxyl of anhydrotetronic acid. The acid $C_6H_{12}O_4$ is therefore regarded as a β -(2-hydroxybutanolide-1)-butyric acid (V).

(III.)

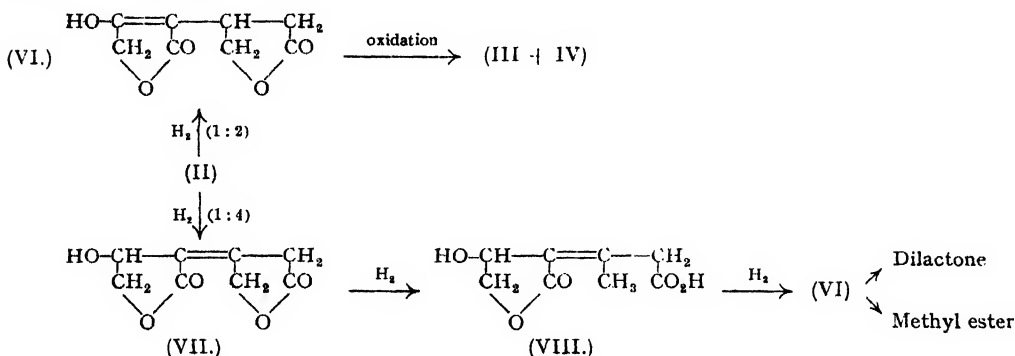

(IV.)

(V.)

These results suffice to establish beyond reasonable doubt structure (II) for anhydrotetronic acid. The course of the hydrogenation described above is explained on the basis of this structure according to the scheme given below. Addition of hydrogen in the 1 : 2-position of the conjugated system would give (VI), probably the major component of the acidic fraction, since as a substituted tetronic acid its further hydrogenation would be slow (Kumler, *J. Amer. Chem. Soc.*, 1938, 60, 859); oxidation of (VI) would yield tricarballic and homoparaconic acids. Addition of hydrogen in the 1 : 4-position would yield (VII) as initial product in which ready hydrogenolysis of one lactone ring would occur giving (VIII). Further hydrogenation of (VIII) would yield the lactonic acid (V), which either lactonises or is esterified by the solvent under the conditions of hydrogenation (cf. Waser, *Helv. Chim. Acta*, 1925, 8, 117) giving the neutral fraction isolated.

The fact that α -substituted tetronic acids are recovered unchanged after treatment under conditions leading to the formation of anhydrotetronic acid (II) from tetronic acid is readily understood, but failure to prepare corresponding anhydro-acids from γ -substituted tetronic acids is rather surprising. On heating an aqueous solution of tetronic acid, the formation of anhydrotetronic acid can be followed by the rise in equivalent. Under similar conditions a definite, although smaller, rise in equivalent was observed with γ -methyltetronic acid (54% increase in 90 minutes) or $\gamma\gamma$ -dimethyltetronic acid (7% increase in 90 minutes), indicating that some condensation had occurred; no anhydro-acids could be isolated from the resulting solutions, nor could the starting material be recovered. Like α -acetyltetronic acid (Baker, Grice, and Jansen, *J.*, 1943, 241), anhydrotetronic acid ($pK = 1.99$) is a much stronger acid than tetronic acid which has $pK = 3.76$ (Kumler, *loc. cit.*), and as in the case of α -acetyltetronic acid this increase can be attributed to the increased resonance possibilities in the ionised form. Structural models show that substitution on the γ -carbon atom of tetronic acid would prevent the derived anhydro-acid from assuming a planar configuration, with consequent loss of resonance possibilities. As a result the derived anhydro-acid would be less stable and might decompose rapidly after formation or the condensation might take a different course after the initial aldol stage; either possibility would explain the experimental results.

EXPERIMENTAL.

Anhydrotetronic Acid.—(1) *In water.* Tetronic acid (5 g.) in water (15 c.c.) was refluxed for 10 minutes. On cooling, anhydrotetronic acid separated in small crystals (1.6 g.), m. p. 261° . Recrystallised from water it had m. p. 263° (decomp.).

(2) *In aqueous morpholine.* Tetronic acid (1.75 g.) in water (10 c.c.) and morpholine (1 c.c.) were refluxed for 10 minutes; the solution was cooled and acidified with sulphuric acid, giving 1.6 g. of

anhydrotetronic acid, m. p. 260° (decomp.). Recrystallised from water it had m. p. 263° (decomp.). Light absorption in alcohol: maxima at 3100 Å. (ϵ , 14,200) and 2560 Å. (ϵ , 9600).

Methyl Ether of Anhydrotetronic Acid.—Anhydrotetronic acid (200 mg.) in cold methanol (25 c.c.) was treated with excess of ethereal diazomethane. The solution was left overnight and then evaporated under reduced pressure, the residual oil was diluted with ether, and the brownish needles were collected and recrystallised from methanol (charcoal). The ether formed colourless plates, m. p. 185° (colours on heating) [Found: C, 55.0; H, 4.1; OMe, 16.1. $C_9H_8O_6$ requires C, 55.1; H, 4.1; OMe (1), 15.8%].

Bromination of Anhydrotetronic Acid.—Anhydrotetronic acid (100 mg.) in a few drops of water was covered with chloroform (2 c.c.), and a solution of bromine in chloroform (1 g. of bromine in 10 c.c. of chloroform) added slowly with shaking. Reaction appeared to be complete when 0.7 c.c. of solution had been added. The solution was filtered and allowed to evaporate at room temperature; a glass resulted which gradually solidified on standing to a hard white powder, m. p. 144–146°. Attempts to recrystallise the bromo-derivative failed [Found: C, 34.5; H, 2.7. $C_9H_5O_6Br$ requires C, 34.4; H, 2.5%].

Oxidation of Anhydrotetronic Acid with Potassium Permanganate.—Anhydrotetronic acid (404 mg.) in water (20 c.c.) was treated with potassium permanganate solution (1.5 g. in 100 c.c. of solution), of which 10 c.c. were taken up (ca. 5 atoms of oxygen). The solution was filtered and acidified with dilute sulphuric acid. Volatile acid corresponding to 8.5 c.c. of N/10-sodium hydroxide was removed by steam distillation. The residual solution was exhaustively extracted with ether, evaporation of which gave a yellow solid (340 mg.). Recrystallised from ether it gave colourless prisms, m. p. 102°; these were concluded to be oxalic acid from equivalent determination (Found: equiv., 64. Calc. for $C_2H_2O_4 \cdot 2H_2O$: equiv., 63) and from the fact that they gave an insoluble calcium salt.

Potassium Hydroxide Fusion of Anhydrotetronic Acid.—Anhydrotetronic acid (250 mg.), potassium hydroxide (1 g.), and water (1 c.c.) were heated in a nickel crucible until fused. The melt was deep red at first but became yellow as the temperature was raised. When the temperature reached 250°, a further quantity (1 g.) of potassium hydroxide was added. The temperature was then raised to 300° and maintained for 10 minutes. The cooled melt was dissolved in water, acidified, and extracted with ether, evaporation of which left a brownish solid smelling of acetic acid. The residue was dissolved in water and the volatile acid removed by steam distillation. The steam distillate required 7.85 c.c. of N/10-sodium hydroxide (equivalent to 47.1 mg. of acetic acid; 0.7 mol.) for neutralisation. After neutralisation the distillate was evaporated and the sodium salt refluxed with *p*-phenylphenacyl bromide in alcohol. On cooling a *p*-phenylphenacyl ester separated. Recrystallised from alcohol it had m. p. 108–109°, undepressed by the *p*-phenylphenacyl ester of acetic acid.

Extraction of the steam distillation residue gave 126 mg. of oxalic acid which, recrystallised from ether, had m. p. 98–100° (Found: equiv., 62). The amount of oxalic acid obtained corresponded to 0.7 mol.

Treatment of Anhydrotetronic Acid with Sulphuric Acid.—Anhydrotetronic acid (508 mg.) was refluxed with N-sulphuric acid in a stream of nitrogen, the carbon dioxide evolved being collected in barium hydroxide solution.

Time (hrs.)	0.5	2.5	6.5	14.5	16.5
CO ₂ (% mol.)	5.6	27.9	55.0	108.0	110.0

The reaction mixture was made alkaline and extracted with ether; no neutral fraction was obtained. On reacidification of the solution and extraction with ether it gave a brown resinous oil (400 mg.) (equiv., 135). The resin reduced Tollens's reagent and gave a positive Legal reaction; with ferric chloride it gave a weak green colour. When the acid (50 mg.) was treated with *p*-phenylphenacyl bromide in the usual manner it gave a colourless crystalline ester, m. p. 156–158° after recrystallisation from ethanol (Found: C, 75.3; H, 5.5. $C_{21}H_{18}O_4$ requires C, 75.4; H, 5.4%). Anhydrotetronic acid was recovered unchanged after being heated on the steam-bath for 2 hours with 2% oleum.

Hydrogenation of Anhydrotetronic Acid.—Anhydrotetronic acid (3 g.) in methanol (75 c.c.) was shaken with hydrogen in presence of platinum (from 0.25 g. of platinum oxide), 859 c.c. being absorbed in 4 hours. The catalyst was then removed and the methanol evaporated; water was added and the solution neutralised with N/10-sodium hydroxide and extracted continuously with ether for 24 hours. The ether was dried and removed, giving a neutral residue (0.9 g.), which distilled as a pale yellow viscous oil, b. p. 180–190° (bath temp.)/10⁻⁵ mm., stable to potassium permanganate in the cold [Found: C, 54.5; H, 6.6; OMe, 4.5; active H₂, 0.22; *M* (Rast), 210; equiv. by hydrolytic titration, 101, 98. Calc. for $C_8H_{14}O_6$: C, 53.5; H, 6.9; OMe (1), 15.3; active H₂ (1), 0.50%; *M*, 202; equiv. (2 potential CO₂H), 101. Calc. for $C_8H_{10}O_4$: C, 56.4; H, 5.9%; *M*, 170; equiv., 85]. Acidification of the alkaline solution followed by extraction with ether gave a semi-solid acid fraction (2 g.) (1st equiv., 221 in cold; 2nd equiv., 198 in warm. Calc. for $C_8H_8O_6$: 1st equiv., 184; 2nd equiv., 184). The substance was acid to Congo-red and was rapidly oxidised by permanganate in the cold. It was soluble in cold alkali and gave a maroon colour with ferric chloride. Light absorption in alcohol: maximum at 2330 Å. (ϵ , 5000).

Hydrazides from Neutral Fraction from Hydrogenation.—The above neutral fraction (0.2 g.) was heated with hydrazine (1 g.) on a steam-bath for 3½ hours. Excess of hydrazine was removed under reduced pressure leaving a crystalline residue. Extraction with boiling methanol gave a crystalline almost insoluble dihydrazide, m. p. 155° (Found: C, 40.9; H, 7.5; N, 23.5. $C_8H_{14}O_4N_4$ requires C, 41.1; H, 7.7; N, 23.9%). The methanol extract was diluted with ethyl acetate and yielded a mixture of isomeric dihydrazides, m. p. 125–140° (Found: N, 23.9. Calc. for $C_8H_{14}O_4N_4$: N, 23.9%). The dihydrazide, m. p. 155° (13.4 mg.; 0.0573 $\times 10^{-3}$ mol.), in water was treated with 1 c.c. of 0.235M-sodium periodate; 0.173 $\times 10^{-3}$ mol. of periodate was absorbed (i.e., 3.02 mols. of periodate per mol. of dihydrazide). The mixed dihydrazides (21.0 mg.) were treated with 2 c.c. of 0.235M-sodium periodate and used up 1.095 c.c. (i.e., 2.89 mols. per mol.).

Oxidation of Benzhydrazide with Periodate.—Benzhydrazide (131.5 mg.; 0.968 $\times 10^{-3}$ mol.) treated with 5 c.c. of 0.235M-periodate used up 4.05 c.c., i.e., 0.982 mols. per mol. The solid which separated, recrystallised from aqueous methanol, had m. p. 238–239° alone or mixed with dibenzoylhydrazine, m. p. 239°.

Oxidation of the Acid Fraction from Hydrogenation.—The acid fraction (1.17 g.) from the above hydrogenation was dissolved in acetone (20 c.c.) and water (20 c.c.), and 2% potassium permanganate was added dropwise with stirring at room temperature. When 3 atoms of oxygen had been taken up the rate of oxidation slowed considerably; in all 6 atoms of oxygen were added. The solution was filtered, acidified, and extracted with ether. On standing, crystalline material separated from the ether, m. p. 157–159°, undepressed in admixture with authentic tricarballic acid (m. p. 158–159°). The solution was evaporated, giving an oil which subsequently crystallised and then had m. p. 70–73°. Recrystallised from chloroform-carbon disulphide it had m. p. 78°. Sublimation in a vacuum (70°/10⁻⁵ mm.) gave colourless prisms, m. p. 80–81.5° (Found: C, 50.2; H, 5.9. Calc. for C₆H₃O₄: C, 50.0; H, 5.6%). The m. p. was not depressed on admixture with authentic homoparaconic acid (m. p. 82–82.5°; Polyakova, Preobrazhenskii, and Preobrazhenskii, *J. Gen. Chem. Russia*, 1939, 9, 1402).

Grants from the Agricultural Research Council in aid of this work are gratefully acknowledged.

UNIVERSITY CHEMICAL LABORATORY, CAMBRIDGE.

254. *Synthesis of ω -Aminoalkyl Cyanides.*

By ALAN A. GOLDBERG and WILLIAM KELLY.

A number of ω -aminoalkyl cyanides have been prepared by interaction of ω -bromoalkyl cyanides with potassium phthalimide followed by deacylation of the resulting ω -cyanoalkyl-phthalimides with hydrazine. The synthetic method would appear to be general for the production of any ω -aminoalkyl cyanide.

THE literature relating to aminoalkyl cyanides is not extensive. Aminomethyl cyanide (Klages, *J. pr. Chem.*, 1902, 65, 188; Anslow and King, *J.*, 1929, 2463; Menge, *J. Amer. Chem. Soc.*, 1934, 56, 2197), 1-aminoethyl cyanide (Dubsky, *Ber.*, 1916, 49, 1048), 2-aminoethyl cyanide (Whitmore *et al.*, *J. Amer. Chem. Soc.*, 1944, 66, 725), and 2-aminopropyl cyanide (Bruylants, *Bull. Soc. chim. Belg.*, 1923, 32, 256) have been prepared by special methods not of general application. In addition, ω -aminoamyl cyanide has been prepared by the high pressure semihydrogenation of adiponitrile (U.S.P.P. 2,208,598, 2,234,566).

ω -Aminoalkyl cyanides were required for the synthesis of a group of new aminoalkyl substituted heterocycles, and a convenient and general method was sought for their preparation. It has been found that ω -cyanoalkylphthalimides, readily available from potassium phthalimide and ω -bromoalkyl cyanides or from ω -bromoalkylphthalimides and potassium cyanide, can be deacylated with hydrazine by the Ing and Manske reaction (*J.*, 1926, 2348) with production of the aminoalkyl cyanide in substantial yield. It is of interest that the intermediate formed by the interaction of hydrazine and the phthalimidoalkyl cyanide yields phthalyl hydrazide and the aminoalkyl cyanide on acidification with hydrochloric acid without prolonged hydrolysis; this accords with the recent observations of Mosher (*J. Amer. Chem. Soc.*, 1946, 68, 1565) on the decomposition of similar compounds. Deacylation with constant-boiling hydrochloric acid or by the modified method of Gabriel (*cf. Ber.*, 1911, 44, 3632) with 5*N*-hydrochloric acid *via* the phthalamic acid is not possible owing to simultaneous hydrolysis of the cyano-group. Since various $\omega\omega$ -alkylenediols are now available which are readily converted through the alkylene dibromides into the corresponding ω -bromoalkyl cyanides, and an $\omega\omega$ -alkylene dibromide, Br[CH₂]_{*n*}Br, can be transformed into the ω -bromoalkyl cyanide, Br[CH₂]_{*n*+1}CN (*cf. Willstätter and Ettlinger, Annalen*, 1903, 326, 99; Leuchs, *Ber.*, 1911, 44, 1510; Cheney and Piening, *J. Amer. Chem. Soc.*, 1945, 67, 731; Breslow and Hansen, *ibid.*, p. 686), the method appears to be general for the synthesis of ω -aminoalkyl cyanides.

In this manner 3-amino-*n*-propyl cyanide, 5-amino-*n*-amyl cyanide, and 10-amino-*n*-decyl cyanide have been obtained. Contrary to the impression given by the literature the aminoalkyl cyanides are stable provided they are kept under anhydrous conditions. Protection of the amino-group by acylation allows the terminal cyano-group to undergo its functional reactions—*e.g.*, thioamide, imino-ether, and amidine transformation—and, often, subsequent formation of the 2-(acylamidoalkyl) heterocycle. The synthesis of a series of 2-(ω -aminoalkyl)-thiazoles and -pyrimidines from these acylamidoalkyl cyanides is described in the following paper; the synthesis of a number of 2-(ω -aminoalkyl)-iminazoles and -iminazolines will be reported shortly.

EXPERIMENTAL.

3-Phthalimido-*n*-propyl Cyanide.—A solution of potassium cyanide (75 g.) in water (150 c.c.) was added dropwise during 1½ hours to a stirred refluxing solution of trimethylene dibromide (202 g.) in alcohol (300 c.c.). Stirring at the reflux was continued for a further 1 hour, water (750 c.c.) added, and the solution extracted with chloroform (3 × 150 c.c.). The combined extracts after drying and

distillation yielded recovered trimethylene dibromide (41 g.), b. p. $55^{\circ}/14$ mm., 3-bromopropyl cyanide (45 g.), b. p. $90-92^{\circ}/13$ mm., and tetramethylene dicyanide (17 g.), b. p. $138-140^{\circ}/13$ mm. (cf. Gabriel, *Ber.*, 1889, **22**, 3336).

Potassium phthalimide (60 g.) was refluxed with a solution of 3-bromopropyl cyanide (44 g.) in absolute alcohol (200 c.c.) for 10 hours, alcohol (ca. 100 c.c.) distilled off, and the residual solution poured into water (1 l.). The oil which separated rapidly solidified (56 g.; m. p. 60°); it was collected and recrystallised from dilute methyl alcohol, 3-phthalimidopropyl cyanide being obtained in white plates, m. p. $65-66^{\circ}$ (Found: N, 13.2. $C_{12}H_{16}O_2N_2$ requires N, 13.1%).

3-Amino-n-propyl Cyanide.—Hydrazine hydrate (50% w/w solution; 25.5 g.) was added to a solution of the foregoing phthalimido-cyanide (40 g.) in alcohol (150 c.c.) at 50° and the resulting solution allowed to cool and kept at room temperature for 1 hour. Water (50 c.c.) was added, and the solution rendered just acid to Congo-red by concentrated hydrochloric acid, warmed to 60° , and kept for 2 hours. The insoluble phthalyl hydrazide was removed and the filtrate evaporated at reduced pressure at $<40^{\circ}$ to small volume. The residue was chilled, basified with 10N-sodium hydroxide (150 c.c.), extracted with ether (5×100 c.c.), the ethereal solution dried, and anhydrous alcoholic hydrogen chloride (10% w/w) added in order to precipitate the hydrochloride (10.5 g.; m. p. $134-136^{\circ}$); recrystallisation from anhydrous alcohol gave 3-amino-n-propyl cyanide hydrochloride in white plates, m. p. $138-140^{\circ}$ (Found: N, 23.0; Cl, 29.8. $C_4H_8N_2 \cdot HCl$ requires N, 23.2; Cl, 29.5%). The hydrochloride (20 g.) was added to 10N-sodium hydroxide (50 c.c.) and the whole thoroughly extracted with ether; after drying over potassium carbonate the ethereal solution was distilled, 3-amino-n-propyl cyanide being obtained as a colourless water soluble oil, b. p. $95-97^{\circ}/20$ mm. (Found: N, 33.8. $C_4H_8N_2$ requires N, 33.4%).

3-Benzamidopropyl Cyanide.—Benzoyl chloride (21 c.c.) was added dropwise during $\frac{1}{2}$ hour to a rapidly stirred solution of sodium carbonate (25 g.) and 3-aminopropyl cyanide hydrochloride (20 g.) in water (200 c.c.) at 15° . Stirring at room temperature was continued for 2 hours, and the white insoluble 3-benzamidopropyl cyanide collected, washed with water and dried in a vacuum; yield 25 g., m. p. $74-76^{\circ}$. For analysis a sample was recrystallised from aqueous methyl alcohol and obtained in colourless nacreous plates, m. p. $78-80^{\circ}$ (Found: C, 70.0; H, 6.5; N, 15.1. $C_{11}H_{12}ON_2$ requires C, 70.3; H, 6.4; N, 14.9%).

5-Phthalimido-n-amyl Cyanide.—5-Bromopentanecarboxylic acid was obtained by the action of hydrobromic-sulphuric acids on the lactone mixture obtained by the potassium persulphate oxidation of cyclohexanone (Brown and Partridge, *J. Amer. Chem. Soc.*, 1944, **66**, 839; Robinson and Smith, *J.*, 1937, 371). This was converted in 86% yield into the amide and the latter into 5-bromoamyl cyanide in 80% yield by the method of Breslow and Hansen (*J. Amer. Chem. Soc.*, 1945, **67**, 686).

Potassium phthalimide (50 g.) was refluxed with a solution of 5-bromoamyl cyanide (45 g.) in anhydrous alcohol (150 c.c.) for 24 hours. Alcohol (ca. 125 c.c.) was distilled off, water (125 c.c.) added, and the solution extracted with ether. Removal of the ether from the dried solution yielded 5-phthalimidoamyl cyanide (52 g.) as an oil which could not be induced to crystallise (cf. Albert, *Ber.*, 1909, **42**, 557).

5-Amino-n-amyl Cyanide.—Hydrazine hydrate (50% w/w aqueous solution; 72 g.) was refluxed with a solution of 5-phthalimidoamyl cyanide (152 g.) in alcohol (300 c.c.) for 1 hour and the solution left overnight. The solid mass was dissolved in water (1000 c.c.), the solution rendered just acid to Congo-red by the addition of 10N-hydrochloric acid (ca. 120 c.c.), and the precipitate of phthalyl hydrazide removed. The filtrate and washings were evaporated to small volume under reduced pressure at $<40^{\circ}$, and the chilled residue was basified with 10N-sodium hydroxide and extracted with chloroform (3×100 c.c.). The extract was dried (K_2CO_3) and distilled, 5-aminoamyl cyanide (52 g.) being obtained as a colourless oil, b. p. $116-118^{\circ}/14$ mm. (Found: N, 24.8. $C_6H_{12}N_2$ requires N, 25.0%).

A solution of the foregoing base (11.1 g.) and sodium carbonate (7.5 g.) in water (100 c.c.) was stirred at 15° and benzoyl chloride (11.3 c.c.) added slowly. Stirring was continued for a further 2 hours, and the precipitated 5-benzamidoamyl cyanide collected, washed with cold water, and dried in a vacuum; yield 18.6 g., m. p. $94-96^{\circ}$. A sample crystallised from benzene-ligroin in colourless acicular prisms, m. p. 98° (Found: C, 72.1; H, 7.4; N, 13.3. Calc. for $C_{13}H_{16}ON_2$: C, 72.2; H, 7.5; N, 13.0%). Von Braun and Steindorff (*Ber.*, 1904, **37**, 2915) prepared this compound from N-benzoylpiperidine and record m. p. 96° (cf. Ainley and King, *Proc. Roy. Soc.*, 1938, **125**, B, 60). A solution of 5-aminoamyl cyanide (2.0 g.) and sodium carbonate (3.5 g.) in 50% acetone (50 c.c.) was stirred at 20° with p-acetamidobenzenesulphonyl chloride (4.2 g.) for 1 hour. The 5-(p-acetamidobenzenesulphonamido)amyl cyanide (5.1 g.; m. p. 112°) was filtered off and washed with water; it separated from dilute methyl alcohol in colourless plates, m. p. 114° (Found: N, 13.8; S, 10.5. $C_{14}H_{18}O_2N_2S$ requires N, 13.6; S, 10.4%).

10-Bromodecyl Cyanide.—A mixture of 10-bromodecanecarboxylic acid (102 g.; Ashton and Smith, *J.*, 1934, 438) and thionyl chloride (150 c.c.) was kept at room temperature for $\frac{1}{4}$ hours and then refluxed for a further $\frac{1}{4}$ hour. The excess of thionyl chloride was distilled off at reduced pressure and the residual oil added slowly to rapidly stirred aqueous ammonia (d 0.88; 1000 c.c.) at 10° . Stirring was continued for a further 2 hours and the pale brown precipitate of 10-bromodecanecarboxylamide (98 g.; m. p. $84-86^{\circ}$) collected, washed with water, and dried in a vacuum. A sample crystallised from benzene in cream plates, m. p. 90° (Found: N, 5.6; Br, 29.8. Calc. for $C_{11}H_{23}ONBr$: N, 5.3; Br, 30.3%). In one preparation the crude acid chloride was distilled and obtained as a colourless oil, b. p. $176-178^{\circ}/1$ mm., but distillation was normally found to be unnecessary.

The foregoing amide (98 g.) was refluxed with thionyl chloride (100 c.c.) for 75 minutes. After removal of the excess thionyl chloride the residue was distilled and yielded 10-bromodecyl cyanide (86 g.) as a pale golden oil, b. p. $158-164^{\circ}/4$ mm. (cf. Trunel, *Compt. rend.*, 1933, **197**, 453) (Found in redistilled sample: N, 5.5; Br, 31.9. $C_{11}H_{23}NBr$ requires N, 5.7; Br, 32.4%).

10-Phthalimidodecyl Cyanide.—10-Bromodecyl cyanide (84 g.) and potassium phthalimide (66 g.) were refluxed with alcohol (200 c.c.) for 24 hours. Alcohol (160 c.c.) was distilled off, and the residue, after the addition of water (500 c.c.), extracted with chloroform (2×150 c.c.). The extract was dried (K_2CO_3) and the chloroform removed to leave 10-phthalimidodecyl cyanide (97 g.) as a brown oil which failed to crystallise.

10-Amino-n-decyl Cyanide.—A solution of the foregoing phthalimidocyanide (76 g.) in methyl alcohol (200 c.c.) was refluxed for 1 hour with 50% w/w hydrazine hydrate (30 g.) and then kept at 20° overnight. Water (1000 c.c.) was added followed by 10N-hydrochloric acid until an acid reaction to Congo-red was obtained, the precipitate removed, and the filtrate evaporated to small volume at reduced pressure at <40°, the residue strongly basified with cold 10N-sodium hydroxide and extracted with chloroform. After drying over potassium carbonate, the chloroform solution yielded 10-amino-decyl cyanide as an amber water-soluble oil (29 g.), b. p. 138–142°/2 mm.; on redistillation it was obtained as a colourless oil, b. p. 136–138°/2 mm. (Found: N, 15.0. $C_{11}H_{22}N_2$ requires N, 15.4%).

Benzoyl chloride (7.8 g.) was added dropwise to a stirred mixture of the foregoing amino-cyanide (10.0 g.), sodium carbonate (10 g.), and water (100 c.c.) at 15°. Stirring was continued for 1 hour, and the precipitated 10-benzamidodecyl cyanide collected, washed with water and dried in a vacuum (15.4 g.; m. p. 54°); it crystallised from benzene-ligroin in colourless needles, m. p. 64° (Found: C, 75.4; H, 9.1; N, 10.0. $C_{18}H_{26}ON_2$ requires C, 75.5; H, 9.1; N, 9.8%).

Interaction of the aminocyanide with *p*-acetamidobenzenesulphonyl chloride in the presence of sodium carbonate in aqueous acetone in the same manner as described above yielded 10-(*p*-acetamidobenzenesulphonamido)decyl cyanide, which separated from aqueous methyl alcohol in colourless needles, m. p. 94° (Found: N, 11.3; S, 8.2. $C_{19}H_{28}O_3N_2S$ requires N, 11.1; S, 8.4%).

Aminomethyl Cyanide Hydrochloride.—Calcium carbonate (50 g.) was added portionwise to a rapidly stirred solution of aminomethyl cyanide sulphate (50 g.; *Org. Synth.*, Coll. Vol. I, 298) in water (200 c.c.). The excess of calcium carbonate and calcium sulphate were filtered off, and the solution acidified to Congo-red with hydrochloric acid and evaporated to dryness at reduced pressure at <40°. The residue was washed with a small amount of cold alcohol and recrystallised from methyl alcohol-diethyl ether, aminomethyl cyanide hydrochloride being obtained in colourless plates, m. p. 144–146°, which slowly turned purple in contact with the air (Found: N, 30.5; Cl, 37.9. Calc. for $C_2H_4N_2 \cdot HCl$: N, 30.3; Cl, 38.4%) (Menge, *loc. cit.*, gives m. p. 165° darkening at 135°).

Benzamidomethyl Cyanide.—Benzoyl chloride (50 g.) was added dropwise to a rapidly stirred solution of aminomethyl cyanide sulphate (50 g.) and sodium carbonate (70 g.) in water (150 c.c.), the temperature not being allowed to exceed 15°. Stirring was continued at room temperature for 8 hours, and the white insoluble benzamidomethyl cyanide collected, washed with water, and dried; yield 44 g., m. p. 136–138°. A sample crystallised from methyl alcohol in colourless rectangular plates, m. p. 142–144° (Found: N, 17.7. $C_6H_9ON_2$ requires N, 17.5%).

***p*-Acetamidobenzenesulphonamidomethyl Cyanide** (cf. Cocker, *J.*, 1940, 1574).—Sodium carbonate (20 g.) was added to a cold rapidly stirred solution of aminomethyl cyanide sulphate (16.4 g.) in water (50 c.c.); acetone (80 c.c.) was added followed by finely divided *p*-acetamidobenzenesulphonyl chloride (20 g.), and the mixture stirred at room temperature for 3 hours. After the addition of water (50 c.c.) the insoluble *p*-acetamidobenzenesulphonamidomethyl cyanide (17 g.; m. p. 190–192°) was collected, washed with water, and dried; a sample separated from ethyl alcohol in colourless leaves, m. p. 192° (Found: N, 16.8; S, 12.8. Calc. for $C_{10}H_{11}O_3N_2S$: N, 16.6; S, 12.7%).

1-Aminoethyl Cyanide (cf. Dubsky, *loc. cit.*).—A solution of potassium cyanide (80 g.) in water (200 c.c.) was added slowly to a stirred mixture of ammonium chloride (72 g.), ether (600 c.c.), and acetaldehyde (32 g.) at 10°. Stirring was continued for 12 hours at 15°, the ether layer separated, and the aqueous layer extracted with ether (2 \times 100 c.c.). The combined ether solutions were completely dried over ignited potassium carbonate, the ether removed, and the residual oil distilled, 1-aminoethyl cyanide (25 g.) being obtained as a colourless oil, b. p. 53–55°/14 mm. A sample which had been kept for 6 months at 20° under anhydrous conditions redistilled at the same b. p. leaving no residue; a sample kept in the presence of moisture became full of crystalline solid after several weeks. The hydrochloride was obtained in colourless needles, m. p. 144–146°, by the addition of absolute ethereal hydrogen chloride to a solution of the base in absolute alcohol (Found: N, 26.7; Cl, 33.3. $C_3H_5N_2 \cdot HCl$ requires N, 26.3; Cl, 33.3%).

1-Benzamidoethyl Cyanide.—Benzoyl chloride (19 g.) was added dropwise to a stirred solution of 1-aminoethyl cyanide (8.6 g.) and sodium carbonate (10 g.) in water (20 c.c.) maintained at 15° by external cooling. Stirring was continued for 10 hours, and the precipitate of 1-benzamidoethyl cyanide (15.0 g.; m. p. 102–104°) collected, washed with cold water and dried in a vacuum; a sample separated from benzene in colourless needles, m. p. 108° (Found: C, 68.9; H, 5.8; N, 16.4. $C_{10}H_{10}ON_2$ requires C, 69.0; H, 5.8; N, 16.1%).

2-Benzamidoethyl Cyanide.—2-Aminoethyl cyanide was obtained by the method of Whitmore *et al.* (*loc. cit.*). The best yields were obtained by standing the mixture of vinyl cyanide and ammonia at ca. 30° for 48 hours in a glass pressure bottle; 120 g. of freshly distilled vinyl cyanide yielded 40 g. of 2-aminoethyl cyanide, b. p. 80–85°/17 mm., and 80 g. of bis-compound, b. p. 200–220°/12 mm. It was found essential to use a 10-inch Vigreux column for removal of the aqueous ammonia since the aminocyanide is slightly volatile in water vapour.

Benzoyl chloride (80 c.c.) and 5N-sodium hydroxide (180 c.c.) were added simultaneously to a rapidly stirred solution of the foregoing amino-cyanide (40 g.) in water (120 c.c.) in such a manner that the mixture was maintained throughout at 10–12° and at pH 8.5–10.0. After the addition (45 minutes) the mixture was stirred at room temperature for a further 2 hours, and the 2-benzamidoethyl cyanide filtered off, washed with dilute sodium carbonate and water, and dried in a vacuum at 20–30°. Yield, 92 g. of a white powder, m. p. 94–96°, which was pure enough for further use; a sample crystallised from 10% alcohol in colourless needles, m. p. 96–98° (Found: N, 16.3. Calc. for $C_{10}H_{10}ON_2$: N, 16.1%).

The authors thank Mr. N. Virgo for some of the analyses.

255. Synthesis of the 2- ω -Aminoalkyl and 2- ω -Sulphanilamidoalkyl Derivatives of Thiazole and Pyrimidine.

By ALAN A. GOLDBERG and WILLIAM KELLY.

4 : 6-Dimethyl-2-aminomethylpyrimidine and a series of 4-methyl-2- ω -aminoalkylthiazoles have been synthesised from the acylamidoalkyl cyanides described in the previous communication. From these new bases homologues of 2-sulphanilamido-4-methylthiazole and 2-sulphanilamido-4 : 6-dimethylpyrimidine have been prepared for examination as bacterial inhibitors.

HOMOLOGUES of sulphanilamide containing the homologising methylene chain between the amino-group and the benzene ring and between the latter and the sulphonamide residue have previously been reported (Miller, Sprague, Kissinger, and McBurney, *J. Amer. Chem. Soc.*, 1940, **62**, 2099; G.P. 726382; Klarer, *Die Chemie*, 1943, **56**, 10; Bergeim and Braker, *J. Amer. Chem. Soc.*, 1944, **66**, 1459). In addition, similar homologues of 2-sulphanilamidothiazole (sulphathiazole) and 2-sulphanilamido-4 : 6-dimethylpyrimidine (sulphadimethylpyrimidine) have been prepared (Bergeim and Braker, *loc. cit.*) and shown to possess activities of a rather lower order against experimental *Cl. perfringens* infections than α -aminotoluene-*p*-sulphonamide (marfanil) (Hamre *et alii*, *Proc. Soc. Exp. Biol. Med.*, 1944, **55**, 170; compare also MacLennan, *Lancet*, 1943, **265**, 123; Schreus and Peltzer, *Klin. Wochenschr.*, 1941, **20**, 1233, 1250; Schreus, *ibid.*, 1942, **21**, 14; Domagk, *ibid.*, p. 448; Klöse and Schrober, *Zentr. Bakt.*, 1942, **149**, 15). It was accordingly of interest to synthesise a series of homologues of sulphathiazole and sulphadimethylpyrimidine in which the homologising chain occupies a position between the sulphonamido-residue and the heterocycle for examination as bacterial inhibitors.

Two methods were employed which would appear to be of general application for the preparation of this type of homosulphathiazole. Conversion of the ω -benzamidoalkyl or ω -phthalimidoalkyl cyanide into the corresponding thioamide, formation of the thiazole ring by condensation with an α -halogeno-aldehyde or -ketone, and hydrolysis of the product readily yielded the 2-(ω -aminoalkyl)thiazole; this was converted by the normal route into the 2-(ω -sulphanilamidoalkyl)thiazole. Alternatively, the ω -acetylsulphanilamidoalkyl cyanide was transformed into the thioamide, the latter treated with the α -halogeno-aldehyde or -ketone, and the resulting 2-(ω -acetylsulphanilamidoalkyl)thiazole deacetylated with aqueous alkali. The overall yields of the 2-aminoalkylthiazoles and 2-(ω -sulphanilamidoalkyl)thiazoles were of a high order with the lower members and also with the highest member of the series. With 5-acylamidoamyl cyanide, however, the normal procedure of hydrogen sulphide addition in the presence of ammonium sulphide gave the corresponding thioamide in yields of the order of only 25%; use of ethanolamine (Yuoh-Fong Chi, *J. Amer. Chem. Soc.*, 1942, **64**, 90) and alkali ethoxide as catalysts (Erlenmeyer, *Helv. Chim. Acta*, 1944, **27**, 412) failed to effect improvement. The α -halogeno-ketones employed were chloroacetone, ethyl α -chloroacetoacetate, ethyl γ -bromoacetoacetate, and ethyl bromopyruvate. It is of interest that a sample of ethyl α -chloroacetoacetate obtained by the action of sulphuryl chloride on ethyl acetoacetate after standing in diffused daylight in a closed bottle for 12 months gave the same high yield of ethyl 4-methyl-2-benzamidomethylthiazole-5-carboxylate on condensation with benzamidothioacetamide as did the freshly prepared compound, whereas Epprecht (*Annalen*, 1894, **278**, 79) states that ethyl α -bromoacetoacetate is not stable and on standing for several weeks isomerises in part to the γ -bromo-compound.

The 4-methyl-2-aminoalkylthiazoles are stable, distillable oils, very soluble in dilute acid; the 4-methyl-2-sulphanilamidoalkylthiazoles are well-crystallised compounds with much lower melting points than sulphathiazole and with considerably more solubility than the latter in water and dilute organic acids. The displacement of the thiazole ring from its adjacency to the sulphonamido-residue allows the basic function of the heterocycle, masked in 2-acetylsulphanilamidothiazole, to reappear; for example, the 2-acetylsulphanilamidoalkylthiazoles are easily soluble in cold aqueous mineral acid, whereas 2-acetylsulphanilamidothiazole is completely insoluble.

Less success was obtained in the case of the attempted preparation of a range of homosulphamethazines. Both benzamidomethyl cyanide and acetylsulphanilamidomethyl cyanide readily yielded the corresponding imino-ethers and amidines and these condensed with acetylacetone to give 4 : 6-dimethyl-2-benzamidomethyl- and -2-acetylsulphanilamidomethylpyrimidine; hydrolysis of the former with acid and the latter with dilute alkali gave respectively 4 : 6-dimethyl-2-aminomethylpyrimidine and 4 : 6-dimethyl-2-sulphanilamidomethylpyrimidine. Benzamidoacetamidine reacted readily with ethyl cyanoacetate but failed to give the expected

pyrimidine derivative; elimination of ammonia from the amidine residue and the reactive methylene group of the ester occurred with formation of ethyl (1-amino-2-benzamidoethylidene)-cyanoacetate in good yield. With malononitrile, benzamidoacetamidine reacted in the same manner with production of 1-amino-2-benzamidoethylidenemalononitrile; compare the similar condensation of ethyl cyanoacetate with formamidine and with benzamidine in the absence of alkali (Kenner *et alii*, J., 1943, 388). The higher homologues of benzamidoacetamidine could not be induced to condense with acetylacetone under any of the varied reaction conditions employed.

Antibacterial Activities.—Infections of medium and low density with *Streptococcus hæmolyticus* (Aronson) were induced in mice by intraperitoneal inoculation of 0.5 c.c. of a 1 : 2000 dilution of a 24-hours old broth subculture of organisms of different virulence; the M.L.D. of the standard organism was 0.5 c.c. of a 1 : 32,000 dilution of the 24-hour old subculture, while the other organism used had been attenuated until the M.L.D. of the 24-hour old subculture was 0.5 c.c. of a 1 : 8000 dilution. Oral administration of daily divided doses of 200–300 mg./kg. of the 4-methyl-2-sulphanilamidomethylthiazoles, Nos. 1423, 1424, 1432, 1433, 1323, and of the sulphanilamidomethyl-4 : 6-dimethylpyrimidine, No. 1427, failed to give complete protection to the mice; in the controls daily administration of 100 mg./kg. of sulphathiazole or sulphadiazine or 150 mg./kg. of sulphanilamide effected complete protection. All the compounds showed a small but nevertheless definite activity in daily doses of 400 mg./kg.

The activity of these homosulphonamides against *Cl. perfringens* infections in mice will be reported elsewhere.

EXPERIMENTAL.

(The acylamidoalkyl cyanides used are described in the previous paper.)

Benzamidothioacetamide.—Ammonia was passed into methyl alcohol (200 c.c.) until the increase in weight was 20 g., followed by hydrogen sulphide until 40 g. had been absorbed. Benzamidomethyl cyanide (50 g.) was added, and the resulting solution kept in a closed vessel at room temperature for 36–48 hours with occasional shaking. After the addition of water (500 c.c.) and standing for 12 hours, benzamidothioacetamide (40 g.; m. p. 152–154°) separated in small crystals. For analysis a sample was recrystallised from aqueous methyl alcohol and obtained in stout colourless prisms, m. p. 154° (Found : N, 14.7; S, 16.6. $C_8H_{10}ON_2S$ requires N, 14.4; S, 16.5%).

4-Methyl-2-benzamidomethylthiazole.—A solution of the foregoing thioamide (31 g.) in methyl alcohol (300 c.c.) and pyridine (25 c.c.) was refluxed with chloroacetone (23 c.c.) for 2 hours. The methyl alcohol was distilled off, water (200 c.c.) added, and the precipitated 4-methyl-2-benzamidomethylthiazole collected (35 g.; m. p. 108°). A sample separated from aqueous methyl alcohol in pale cream needles, m. p. 114–116° (Found : N, 12.3; S, 13.5. $C_{12}H_{12}ON_2S$ requires N, 12.1; S, 13.8%).

4-Methyl-2-aminomethylthiazole.—A solution of 4-methyl-2-benzamidomethylthiazole (35 g.) in 5N-hydrochloric acid (225 c.c.) was refluxed for 3 hours, cooled, the precipitate of benzoic acid removed, and the filtrate evaporated to small volume at reduced pressure. The residue was strongly basified with 10N-sodium hydroxide and extracted with ether (3 \times 100 c.c.); after drying over potassium carbonate and distillation, the ethereal extract yielded 4-methyl-2-aminomethylthiazole (13.5 g.) as a colourless oil, b. p. 82–84°/5 mm. (Found : N, 22.1; S, 24.7. $C_5H_8N_2S$ requires N, 21.8; S, 25.0%).

4-Methyl-2-sulphanilamidomethylthiazole (No. 1423).—4-Methyl-2-aminomethylthiazole (2.5 g.) was heated on the water-bath for $\frac{1}{2}$ hour with a solution of acetylsulphanil chloride (4.7 g.) in anhydrous pyridine (10 c.c.). The mixture was cooled, diluted with water, and the precipitated 4-methyl-2-acetylsulphanilamidomethylthiazole (4.9 g.) collected; this crystallised from aqueous alcohol in cream leaves, m. p. 176° (Found : N, 13.1; S, 19.3. $C_{13}H_{15}O_3N_2S_2$ requires N, 12.9; S, 19.7%).

The foregoing acetamido-compound (4.0 g.) was heated with 2.5N-sodium hydroxide (32 c.c.) at 100° for 1 hour, the solution diluted with water, partly neutralised with acetic acid, the filtered solution (charcoal) acidified with acetic acid, and the precipitate collected. Recrystallisation from aqueous alcohol yielded 4-methyl-2-sulphanilamidomethylthiazole (3.1 g.) in colourless plates, m. p. 124–126° (Found : N, 14.6; S, 23.0. $C_{11}H_{13}O_2N_2S_2$ requires N, 14.8; S, 22.6%).

4-Methyl-2-aminomethylthiazole-5-carboxylic Acid.—A solution of β -benzamidothioacetamide (19.4 g.) in anhydrous methyl alcohol (225 c.c.) and anhydrous pyridine (12 c.c.) was refluxed with ethyl α -chloroacetate (18 c.c.; Dey, J., 1915, 107, 1646) for 5 hours. The solvent was distilled off to incipient crystallisation, and the solution (70 c.c.) chilled, ethyl 4-methyl-2-benzamidomethylthiazole-5-carboxylate (25 g.; m. p. 140°) separating in long colourless needles; by evaporation of the filtrate a further crop (1.5 g.) was obtained (Found, in recrystallised material, m. p. 140–142° : N, 8.9; S, 10.4. $C_{15}H_{15}O_3N_2S$ requires N, 9.2; S, 10.5%).

A solution of the foregoing benzamido-compound (6.1 g.) in methyl alcohol (50 c.c.) was refluxed with 5N-sodium hydroxide (10 c.c.) for 1 hour. After standing overnight at 20° the alcohol was distilled away at reduced pressure, the residue dissolved in water (70 c.c.), filtered (charcoal), and the solution adjusted to pH 4 with hydrochloric acid; 4-methyl-2-benzamidomethylthiazole-5-carboxylic acid (5.0 g.) separated as a microcrystalline precipitate. The acid crystallised from 50% alcohol in glittering white tablets, m. p. 252–254° (decomp.) (Found : N, 10.3; S, 11.7. $C_{13}H_{13}O_3N_2S$ requires N, 10.2; S, 11.6%).

A solution of crude ethyl 4-methyl-2-benzamidomethylthiazole-5-carboxylate (15 g.) in methyl alcohol (200 c.c.) was refluxed with 10N-hydrochloric acid (100 c.c.) for 14 hours. The solution was distilled in a current of steam to remove alcohol and benzoic acid and, after the addition of more hydrochloric acid, evaporated to very small volume; on cooling, 4-methyl-2-aminomethylthiazole-5-carboxylic acid hydrochloride separated in small prisms (6 g.), m. p. 248–250° (decomp.) (Found, in material dried at 120°/1 mm. over phosphoric oxide : N, 13.7; Cl, 16.8. $C_6H_8O_2N_2S.HCl$ requires N, 13.5; Cl, 16.9%).

The foregoing hydrochloride (5 g.) was dissolved in water (12 c.c.) and the solution adjusted to pH 3.5—4.0 by addition of 5*N*-sodium hydroxide (ca. 6 c.c.). When the resulting solution was kept on ice, 4-methyl-2-aminomethylthiazole-5-carboxylic acid (2.8 g.) separated in white plates; these crystallised from 50% alcohol in stellate clusters of colourless feathers, m. p. 282—284° (Found: N, 16.4; S, 18.5. $C_5H_8O_3N_2S$ requires N, 16.3; S, 18.6%).

2-Benzamidomethyl-4-thiazolylacetic Acid.—A solution of benzamidomethylthioacetamide (9.7 g.) in anhydrous methyl alcohol (150 c.c.) and anhydrous pyridine (6 c.c.) was refluxed with ethyl γ -bromoacetate (8.5 c.c.; Epprecht, *loc. cit.*) for 4½ hours. The solvent was distilled away at reduced pressure, the residual oil dissolved in warm 1.5*N*-hydrochloric acid (200 c.c.), and the solution filtered (charcoal) and adjusted to pH 7 with dilute sodium hydroxide; ethyl 2-benzamidomethyl-4-thiazolylacetate (12.5 g.) separated, which crystallised from benzene-ligroin in glittering plates, m. p. 86—88° (Found: N, 9.6; S, 10.9. $C_{15}H_{16}O_3N_2S$ requires N, 9.7; S, 11.0%).

A solution of the foregoing crude benzamido-compound (6 g.) in methyl alcohol (60 c.c.) and 5*N*-sodium hydroxide (10 c.c.) was refluxed for 1 hour. The solvent was removed at reduced pressure, the residue dissolved in a small volume of water, and the filtered solution adjusted to pH 4 with hydrochloric acid; 2-benzamidomethyl-4-thiazolylacetic acid (3 g.) separated in colourless plates, which crystallised from dilute alcohol in glittering plates, m. p. 184—186° (Found: N, 10.3; S, 11.6. $C_{13}H_{12}O_3N_2S$ requires N, 10.2; S, 11.6%).

2-Benzamidomethylthiazole-4-carboxylic Acid.—A solution of freshly prepared and redistilled pyruvic acid (75 g.; 60 c.c.) and toluenesulphonic acid (6 g.) in ethyl alcohol (1250 c.c.) and benzene (300 c.c.) was refluxed under a 12" Widmer column with a 10:1 reflux ratio and solvent removed at the rate of 100 c.c./hour. After 5 hours a further quantity of benzene (300 c.c.) was added and the distillation continued for another 4 hours, solvent being removed at the rate of 240—250 c.c./hour. After standing overnight the residual oil was distilled through a 6" Vigreux column, the solvent being removed first at 760 mm. up to 80° to avoid loss of ester; redistillation of the fraction, b. p. 50—65°/20 mm. (75 g.), yielded 68 g. of ethyl pyruvate as a colourless oil, b. p. 54—60°/20 mm. A solution of dry bromine (25 c.c.) in dry carbon tetrachloride (25 c.c.) was added dropwise during ½ hr. to a refluxing solution of ethyl pyruvate (58 g.) in carbon tetrachloride (100 c.c.). After standing for 3 hours, the oil was distilled and yielded a fraction (82 g.), b. p. 96—100°/10 mm., which on redistillation gave ethyl bromopyruvate (70 g.), b. p. 90—94°/8 mm.

A solution of benzamidothioacetamide (9.7 g.) in dioxan (110 c.c.) and benzene (40 c.c.) was heated on the water-bath with ethyl bromopyruvate (8 c.c.) for 2 hours. The solvent was rapidly distilled away at reduced pressure, the residual oil dissolved in 1.7*N*-hydrochloric acid (300 c.c.), and the solution filtered (charcoal), adjusted at 20° with stirring to pH 7.6 by addition of 5*N*-sodium hydroxide, and the precipitate of ethyl 2-benzamidomethylthiazole-4-carboxylate (5.0 g.; m. p. 76—80°) collected. Adjustment of the filtrate to pH 2.8—3.0 with hydrochloric acid effected precipitation of 2-benzamidomethylthiazole-4-carboxylic acid (5.8 g.; m. p. 176—180°). The ester crystallised from benzene-ligroin in colourless plates, m. p. 82—84° (Found: N, 9.7; S, 10.9. $C_{14}H_{14}O_3N_2S$ requires N, 9.7; S, 11.0%); the acid separated from dilute alcohol in glittering colourless leaves, m. p. 180—182° (Found: N, 10.4; S, 11.9. $C_{12}H_{10}O_3N_2S$ requires N, 10.7; S, 12.2%). Interaction of the thioamide and ethyl bromopyruvate in alcoholic solution in the presence of pyridine yielded a dark gum.

Benzamidoacetamidine Hydrochloride.—A mixture of benzamidomethyl cyanide (40 g.), anhydrous chloroform (300 c.c.), and anhydrous ethyl alcohol (59 c.c.) was saturated at 5° with dry hydrogen chloride; the cyanide dissolved as the hydrogen chloride was passed in and then set to a crystalline mass which redissolved as the solution became saturated. After standing at 4° for 16—20 hours, the chloroform was pumped off at room temperature, and the crystalline residue (53 g.; m. p. 144—146°) of benzamidoacetiminooether hydrochloride, containing ammonium chloride as impurity, was washed with a little dry chloroform and dried in a vacuum (Found: N, 12.2; Cl, 15.8. $C_{11}H_{14}O_2N_2.HCl$ requires N, 11.5; Cl, 14.6%). This was added to alcohol (300 c.c.; lime-dried), which had been previously saturated with dry ammonia at 5°, and the mixture swirled at room temperature until solution was obtained and then allowed to stand in a closed vessel at ca. 4° for 24 hours. After addition of absolute ether (200 c.c.), the crystalline precipitate of benzamidoacetamidine hydrochloride (44 g.), m. p. 184—186°, was collected and dried in a vacuum over sulphuric acid; from alcohol-ether a sample separated in colourless nacreous plates, m. p. 187° (Found: N, 20.1; Cl, 17.1. $C_9H_{11}ON_3.HCl$ requires N, 19.7; Cl, 16.6%). The free amidine, m. p. 132—134°, precipitated by the addition of 5*N*-sodium hydroxide to a cold 20% aqueous solution of the hydrochloride, was unstable and rapidly became converted into benzamidoacetamide, which crystallised from boiling water in large colourless prisms, m. p. 186° (Found: C, 60.8; H, 5.8; N, 16.1. Calc. for $C_9H_{10}O_2N_2$: C, 60.6; H, 5.7; N, 15.7%).

4:6-Dimethyl-2-benzamidomethylpyrimidine.—A solution of benzamidoacetamidine hydrochloride (30 g.) in alcohol (150 c.c.) was refluxed with anhydrous potassium carbonate (20 g.) and acetylacetone (18 g.) for 4 hours. The alcohol was distilled off, water added to the residue, and the precipitated oil, which slowly solidified to a dark gum, lixiviated with warm dilute hydrochloric acid and, after chilling, the insoluble benzamidoacetamide removed. Basification of the filtrate with 5*N*-sodium hydroxide precipitated 4:6-dimethyl-2-benzamidomethylpyrimidine (8.7 g.; m. p. 192—194°), which crystallised from aqueous methyl alcohol (charcoal) in slender colourless needles, m. p. 200° (Found: C, 69.6; H, 6.3; N, 17.8. $C_{14}H_{15}ON_3$ requires C, 69.7; H, 6.3; N, 17.4%). Many modifications of the above procedure failed to increase the yield.

4:6-Dimethyl-2-aminomethylpyrimidine.—A solution of crude 4:6-dimethyl-2-benzamidopyrimidine (36.5 g.) in 5*N*-hydrochloric acid (225 c.c.) was refluxed for 4 hours, cooled, the precipitate of benzoic acid removed, and the filtrate evaporated to dryness under reduced pressure. The residual hydrochloride was dissolved in warm water (200 c.c.), filtered (charcoal), evaporated under reduced pressure to small volume (100 c.c.), chilled, and strongly basified with 5*N*-sodium hydroxide. After standing, the precipitate was collected (22 g.; m. p. 152—156°), drained, boiled with water (250 c.c.), the unchanged benzamido-compound (4.0 g.) removed, and the filtered solution allowed to cool; 4:6-dimethyl-2-aminomethylpyrimidine (17 g.) separated in colourless, hydrated, felted needles which on drying at 100° yielded an

anhydrous white powder, m. p. 168° (Found: C, 61.4; H, 8.1; N, 30.9. $C_7H_{11}N_3$ requires C, 61.3; H, 8.1; N, 30.6%). The monohydrochloride separated from methyl alcohol-ether in slender white needles, m. p. 244–246° (Found: N, 24.3. $C_7H_{11}N_3 \cdot HCl$ requires N, 24.2%).

Acetylsulphanilamidoacetamidine Hydrochloride.—A mixture of acetylsulphanilamidomethyl cyanide (14.6 g.), dry chloroform (100 c.c.), and absolute ethyl alcohol (13.7 c.c.) was saturated with dry hydrogen chloride at 5° and then kept at ca. 4° for 7 days with occasional shaking. The solvents were pumped off at room temperature, the residue mixed with anhydrous alcohol (100 c.c.) which had previously been saturated with dry ammonia, and the solution, which rapidly crystallised, allowed to stand at room temperature for 16 hours. The solvent was pumped off, and the crystalline residue (16 g.; m. p. 160°) of acetylsulphanilamidoacetamidine hydrochloride washed with ether. For analysis a sample was recrystallised from alcohol-ether and obtained in white needles, m. p. 164–166° (Found: N, 19.0; Cl, 12.0. $C_{10}H_{14}O_3N_4S \cdot HCl$ requires N, 18.5; Cl, 11.8%). The free amidine was precipitated from the concentrated aqueous solution of the hydrochloride by 5N-sodium hydroxide but rapidly decomposed to acetylsulphanilamidoacetamide, which crystallised from boiling water in colourless rectangular prisms, m. p. 218–220° (Found: C, 44.1; H, 5.0; N, 16.0. $C_{10}H_{13}O_3N_3S$ requires C, 44.2; H, 4.8; N, 15.9%).

4:6-Dimethyl-2-sulphanilamidomethylpyrimidine (No. 1427).—Acetylsulphanilamidoacetamidine hydrochloride (10 g.), acetylacetone (6.0 c.c.), pyridine (14 c.c.), and water (6 c.c.) were heated together at 100° for 4 hours. Water (20 c.c.) was added, and the precipitate (4.8 g.; m. p. 256°) collected and recrystallised from aqueous alcohol, 4:6-dimethyl-2-acetylsulphanilamidomethylpyrimidine being obtained in slender cream needles, m. p. 260–262° (Found: C, 53.7; H, 5.3; N, 17.2. $C_{15}H_{18}O_3N_4S$ requires C, 53.9; H, 5.4; N, 16.9%).

The foregoing acetamido-compound (7.8 g.) was dissolved in 2.5N-sodium hydroxide (62 c.c.), and the solution heated on the water-bath for 1 hour, cooled, partly neutralised with dilute hydrochloric acid, and filtered (charcoal). Adjustment of the filtrate to pH 7.0 effected separation of 4:6-dimethyl-2-sulphanilamidomethylpyrimidine (6.6 g.) in microscopic needles, m. p. 230–232°, which after a further crystallisation from aqueous alcohol had m. p. 232–234° (Found: N, 19.4; S, 11.0. $C_{15}H_{18}O_3N_4S$ requires N, 19.2; S, 10.6%).

The compound was also obtained by the following route. Acetylsulphanil chloride (3 g.) was added to a solution of 4:6-dimethyl-2-aminomethylpyrimidine (2 g.) and sodium hydrogen carbonate (2 g.) in 60% acetone (50 c.c.). After being warmed on the water-bath for a short time, the mixture was diluted with water, and the precipitate collected. Crystallisation from aqueous alcohol yielded 4:6-dimethyl-2-acetylsulphanilamidomethylpyrimidine in cream needles, m. p. 261–262°, alone and in admixture with a sample prepared as above described.

Condensation of Benzamidoacetamidine with Malononitrile: 1-Amino-2-benzamidoethylidenemalononitrile.—A solution of benzamidoacetamidine hydrochloride (21.3 g.) in anhydrous alcohol (150 c.c.) was converted into the free amidine base by addition of a solution of sodium (2.3 g.) in alcohol (50 c.c.). Malononitrile (7.5 c.c.) was added, and the solution allowed to stand at 40–45°; the mixture rapidly turned orange and in 2 hours developed an ammoniacal odour and began depositing crystals. After 48 hours at this temperature the mixture was chilled, and the crystalline, almost colourless precipitate of 1-amino-2-benzamidoethylidenemalononitrile (25.5 g.; m. p. 206°) collected. A sample crystallised from dilute alcohol in colourless, glistening leaves, m. p. 220–222° (decomp.) with softening at 210° (Found, in material dried at 80°/2 mm. over phosphoric oxide: C, 63.6; H, 4.5; N, 24.9, 25.0. $C_{15}H_{10}ON_4$ requires C, 63.8; H, 4.4; N, 24.8%).

Condensation of Benzamidoacetamidine with Ethyl Cyanoacetate: Ethyl 1-Amino-2-benzamidoethylidenecyanoacetate.—A mixture of ethyl cyanoacetate (12.4 g.) and an anhydrous alcoholic solution of benzamidoacetamidine (prepared as in the foregoing example from 21.3 g. of benzamidoacetamidine hydrochloride in 150 c.c. alcohol and 2.3 g. of sodium in 50 c.c. alcohol) was kept for 48 hours at 40°; crystals rapidly separated with development of an ammoniacal odour. The mixture was chilled, and the crystalline precipitate of ethyl 1-amino-2-benzamidoethylidenecyanoacetate (24 g.; m. p. 196°) collected. A sample separated from dilute alcohol in colourless felted leaves, m. p. 198–200° (Found: C, 61.3; H, 5.4; N, 15.6, 15.5. $C_{14}H_{13}O_3N_3$ requires C, 61.5; H, 5.5; N, 15.4%).

α -Benzamidothiopropionamide.— α -Benzamidopropionitrile (11.2 g.) was added to freshly prepared methanolic ammonium sulphide (obtained by dissolution of 6 g. of ammonia and then 6 g. of hydrogen sulphide in 75 c.c. of methyl alcohol) and the solution kept in a sealed bottle at room temperature for 16 hours. On dilution with water α -benzamidothiopropionamide (7.6 g.) slowly separated; this crystallised from aqueous methyl alcohol in colourless needles, m. p. 146° (Found: N, 13.8; S, 15.4. $C_{10}H_{12}ON_2S$ requires N, 13.5; S, 15.4%).

4-Methyl-2-(1'-aminoethyl)thiazole.—A solution of the foregoing amide (50 g.) in methyl alcohol (200 c.c.) and pyridine (38 c.c.) was refluxed with chloroacetone (24 c.c.) for 2 hours, and the alcohol then distilled off. Addition of water to the residue precipitated 4-methyl-2-(1'-benzamidoethyl)thiazole (50 g.), which crystallised from aqueous methyl alcohol in colourless needles, m. p. 112° (Found: N, 11.6; S, 13.4. $C_{13}H_{14}ON_2S$ requires N, 11.4; S, 13.0%).

A solution of the foregoing crude compound (50 g.) in 5N-hydrochloric acid (400 c.c.) was refluxed for 7 hours, cooled, the benzoic acid removed, and the filtrate evaporated almost to dryness at reduced pressure. Water (300 c.c.) was added, and the solution evaporated to very small volume, cooled, strongly basified with 10N-sodium hydroxide, and extracted with chloroform (2 \times 50 c.c.). After drying and distillation, the chloroform extracts yielded 4-methyl-2-(1'-aminoethyl)thiazole as a colourless oil (21 g.), b. p. 98–100°/12 mm. (Found: N, 20.0; S, 22.5. $C_6H_{10}N_2S$ requires N, 19.7; S, 22.6%).

α -Acetylsulphanilamidothiopropanamide.— α -Acetylsulphanilamidopropionitrile (9.2 g.) was added to freshly prepared methanolic ammonium sulphide (5 g. of ammonia and 5 g. of hydrogen sulphide in 100 c.c. of methyl alcohol), and the mixture kept at 20° with frequent shaking for 24 hours. Addition of water (150 c.c.) caused the thio-amide (6.6 g.) slowly to separate in colourless prisms, m. p. 220; these crystallised from aqueous methyl alcohol in stout prisms, m. p. 226° (Found: N, 14.2; S, 21.1. $C_{11}H_{14}O_3N_2S_2$ requires N, 14.0; S, 21.3%).

4-Methyl-2-(1'-sulphanilamidoethyl)thiazole (No. 1424).—A solution of the foregoing amide (5.0 g.) in

alcohol (50 c.c.), water (5 c.c.), and pyridine (4 c.c.) was refluxed with chloroacetone (2.4 g.) for 2 hours, and the alcohol then distilled off. Addition of water (50 c.c.) precipitated 4-methyl-2-(1'-acetylsulphanilamidoethyl)thiazole (5.2 g.; m. p. 172°) which crystallised from aqueous alcohol in pale cream needles, m. p. 180—182° (Found: N, 12.3; S, 18.6. $C_{14}H_{17}O_2N_3S_2$ requires N, 12.4; S, 18.9%).

Hydrolysis of the foregoing compound (4.2 g.) with 2.5N-sodium hydroxide at 100° for 1 hour yielded 4-methyl-2-(1'-sulphanilamidoethyl)thiazole (2.4 g.), which separated from dilute alcohol in colourless prisms, m. p. 168° (Found: N, 14.5; S, 21.3. $C_{13}H_{15}O_2N_3S_2$ requires N, 14.2; S, 21.6%).

β -Benzamidothiopropionamide.—A solution of β -benzamidothiopropionitrile (42 g.) in 96% alcohol (325 c.c.) containing 3.3% w/w ammonia was saturated with hydrogen sulphide and kept at ca. 40° for 5 days, more hydrogen sulphide being added each day. Solvent was pumped off from the semi-solid mixture, ether in excess added, and the precipitate collected. This was dissolved in 90% methyl alcohol (500 c.c.), the sulphur removed, and the filtrate evaporated to incipient crystallisation (vol. 250 c.c.); on standing in the ice chest, β -benzamidothiopropionamide (30 g.) separated in glittering colourless rhombs, m. p. 160—162°. A further quantity of less pure material was separated from the mother-liquor (Found: N, 13.6; S, 15.2. $C_{10}H_{13}ON_2S$ requires N, 13.5; S, 15.2%). The compound was obtained in similar yield by saturating the cold methyl-alcoholic solution of the nitrile with ammonia and then with hydrogen sulphide and keeping it in a sealed vessel at 40° for 5 days.

4-Methyl-2-(2'-benzamidoethyl)thiazole.—A solution of the foregoing amide (41.6 g.) in anhydrous methyl alcohol (600 c.c.) was refluxed with chloroacetone (24 c.c.) and anhydrous pyridine (32 c.c.) for 4½ hours. After standing overnight the solvent was distilled off, and the oil which separated dissolved in warm N-hydrochloric acid (300 c.c.), the solution filtered (charcoal), and the filtrate adjusted to pH 7.0 with ammonia; 4-methyl-2-(2'-benzamidoethyl)thiazole (40 g.) separated as an oil which solidified on scratching and freezing. The compound was obtained in slender colourless needles, m. p. 74—76°, by dissolution in warm benzene-ligroin and allowing the solvent to evaporate slowly in a current of cold filtered air (Found: C, 64.0; H, 5.9; N, 11.8; S, 13.6. $C_{13}H_{14}ON_2S$ requires C, 63.5; H, 5.7; N, 11.4; S, 13.0%).

4-Methyl-2-(2'-aminoethyl)thiazole.—The foregoing crude benzamido-compound (32 g.) was refluxed for 4 hours with 5N-hydrochloric acid (260 c.c.), the solution chilled, and the precipitated benzoic acid removed. The filtrate was evaporated to small volume, chilled, strongly basified with 10N-sodium hydroxide, and extracted several times with ether; the ethereal solution after drying over potassium carbonate yielded 4-methyl-2-(2'-aminoethyl)thiazole (15 g.) as a colourless oil, b. p. 102—104°/10 mm. (Found: N, 19.8; S, 22.2. $C_8H_{10}N_2S$ requires N, 19.7; S, 22.5%).

4-Methyl-2-(2'-sulphanilamidoethyl)thiazole (No. 1323).—A solution of acetylsulphanil chloride (17 g.) in acetone (50 c.c.) was added dropwise during 45 minutes to a mixture of 4-methyl-2-(2'-aminoethyl)thiazole (10 g.), sodium hydrogen carbonate (10 g.), water (150 c.c.), and acetone (20 c.c.) stirred at 10—15°. Stirring was continued at 20° for a further 4 hours, water (150 c.c.) added, and the precipitate of 4-methyl-2-(2'-acetylsulphanilamidoethyl)thiazole (26 g.; m. p. 110°) collected and washed with water. The compound is insoluble in cold water but easily soluble in cold dilute hydrochloric acid and dilute sodium hydroxide. A sample crystallised from dilute alcohol in colourless needles, m. p. 116—118° (Found, in material dried at 1 mm. over phosphoric oxide: N, 12.3; S, 18.7. $C_{14}H_{17}O_2N_3S_2$ requires N, 12.4; S, 18.9%).

A solution of the foregoing crude acetamido-compound (20 g.) in 2.5N-sodium hydroxide (200 c.c.) was heated on the water-bath for 75 minutes. 10N-Hydrochloric acid (70 c.c.) was added, the solution filtered (charcoal), cooled, and adjusted with simultaneous scratching to pH 6.6—7.0 with dilute sodium hydroxide; 4-methyl-2-(2'-sulphanilamidoethyl)thiazole separated in small colourless crystals (15.8 g.; m. p. 92°), which crystallised from dilute methyl alcohol in elongated needles, m. p. 98—100° (Found, in material dried over phosphoric oxide at 1 mm.: N, 14.4; S, 21.4. $C_{12}H_{15}O_2N_3S_2$ requires N, 14.2; S, 21.6%). The compound is considerably more soluble in cold 5% lactic acid than is sulphathiazole.

β -Benzamidothiopropionamide Hydrochloride.—A solution of β -benzamidothiopropionitrile (35 g.) in anhydrous chloroform (300 c.c.) and anhydrous ethyl alcohol (46 c.c.) was saturated at 5° with dry hydrogen chloride and set aside for 18—24 hours at 0—4°. The solvent was completely pumped off at 20°, and the glittering crystalline residue of β -benzamidothiopropionimino-ether hydrochloride was mixed with cold anhydrous ethyl alcohol (400 c.c.) and saturated with dry ammonia at 5°. The clear solution which resulted was allowed to stand at 5° for 24—30 hours, the ammonia pumped off at 20°, the volume made up to 400 c.c. with lime-dried alcohol, and the solution filtered at the b. p. to remove ammonium chloride and kept on ice; β -benzamidothiopropionamide hydrochloride separated in large colourless transparent cubes (34 g.; m. p. 174—180°) which were collected and dried in a vacuum. From the mother-liquors a further 7 g. (m. p. 178—180°) was obtained by evaporation. A sample recrystallised from anhydrous ethyl alcohol had m. p. 178—180° (Found: N, 18.4; Cl, 16.4. $C_{10}H_{14}ON_2Cl$ requires N, 18.4; Cl, 15.6%).

All attempts to condense this amidine with acetylacetone (i) in dilute alcohol in presence of sodium carbonate at the b. p., (ii) in refluxing anhydrous alcohol in presence of sodium carbonate, (iii) in warm (40°) and in refluxing anhydrous alcohol in presence of 1 mol. or 2 mols. of sodium ethoxide failed to yield any of the required pyrimidine. In (i) a quantitative yield of β -benzamidothiopropionamide was obtained which crystallised from boiling water in heavy colourless prisms, m. p. 174—176° (Found: C, 62.2; H, 6.3; N, 14.6. $C_{10}H_{13}O_2N_3$ requires C, 62.6; H, 6.3; N, 14.6%).

γ -Phthalimidothiobutyramide.—A mixture of 3-phthalimidopropyl cyanide (20 g.) and freshly prepared methanolic ammonium sulphide (5 g. of ammonia and 12 g. of hydrogen sulphide in 120 c.c. of methyl alcohol) was kept at 40° in a closed vessel with frequent shaking for 48 hours. The mixture was chilled, and the precipitated amide (11.5 g.; m. p. 184°) collected; on re-heating the filtrate to 40—45° for 5 days, a further quantity (2 g.) separated. For analysis a sample was recrystallised from alcohol and obtained in colourless needles, m. p. 186° (Found: N, 11.3; S, 13.2. $C_{12}H_{13}O_2N_3S$ requires N, 11.3; S, 12.9%).

4-Methyl-2-(3'-aminoethyl)thiazole.—The above amide (10 g.), chloroacetone (5.6 g.), pyridine (6.5 c.c.), and methyl alcohol (70 c.c.) were refluxed together for 2 hours, the solvent distilled off, and the residue diluted with water. The oil which separated slowly solidified to a crystalline mass (11.2 g.) of

4-methyl-2-(3'-phthalimidopropyl)thiazole, which crystallised from aqueous methyl alcohol in colourless prisms, m. p. 80° (Found: N, 10.0; S, 11.4. $C_{14}H_{14}O_2N_2S$ requires N, 9.8; S, 11.2%).

The foregoing compound (45 g.) was refluxed with 10N-hydrochloric acid (340 c.c.) for 8 hours, the mixture chilled, the phthalic acid removed, and the filtrate evaporated almost to dryness at reduced pressure. Basification of the residue with 10N-sodium hydroxide and extraction with chloroform yielded 4-methyl-2-(3'-aminopropyl)thiazole, which distilled as a colourless oil (19.5 g.), b. p. 120–122°/12 mm. (Found, in redistilled sample: N, 17.8; S, 21.2. $C_7H_{12}N_2S$ requires N, 17.9; S, 20.5%).

4-Methyl-2-(3'-sulphanilamidopropyl)thiazole (No. 1432).—Acetylsulphanilyl chloride (5 g.) was added to a rapidly stirred solution of 4-methyl-2-(3'-aminopropyl)thiazole (3 g.) and sodium hydrogen carbonate (3 g.) in 50% aqueous acetone (25 c.c.), and the mixture stirred for $\frac{1}{2}$ hour at room temperature and then for a further $\frac{1}{2}$ hour at 50–60°. Addition of water precipitated 4-methyl-2-(3'-acetylsulphanilamidopropyl)thiazole (6.2 g.), which crystallised from aqueous methyl alcohol in colourless prisms, m. p. 91° (Found: N, 11.8; S, 17.3. $C_{14}H_{18}O_2N_2S_2$ requires N, 11.9; S, 16.9%). Deacetylation with 2.5N-sodium hydroxide at 100° for 1 hour yielded 4-methyl-2-(3'-sulphanilamidopropyl)thiazole, which separated from aqueous methyl alcohol in colourless needles, m. p. 130–132° (Found: N, 13.8; S, 20.5. $C_{13}H_{17}O_2N_2S_2$ requires N, 13.5; S, 20.6%).

γ -Phthalimidobutyramidine Hydrochloride.—A solution of 3-phthalimidopropyl cyanide (20 g.) in dry chloroform (100 c.c.) and anhydrous alcohol (22 c.c.) was saturated at 5° with dry hydrogen chloride and kept overnight at 5°. The solvent was completely removed at 30° under reduced pressure, anhydrous alcohol (120 c.c.) added, and the solution saturated at 5° with dry ammonia. After standing at 0–5° for 72 hours, the solvent and excess ammonia were distilled away at < 30°; crystallisation of the residue from a small volume of water yielded γ -phthalimidobutyramidine hydrochloride (12 g.) in colourless nacreous plates, m. p. 180–182°; for analysis a sample was recrystallised from alcohol-ether and obtained in colourless plates, m. p. 186° (Found: N, 16.1; Cl, 14.0. $C_{12}H_{13}O_2N_3HCl$ requires N, 15.7; Cl, 13.3%). Attempts to condense this compound with acetylacetone failed to yield any of the desired pyrimidine.

5-Benzamidothiohexoamide.—A solution of 5-benzamido-*n*-amyl cyanide (4 g.) in methyl alcohol (24 c.c.) was saturated with ammonia and then with hydrogen sulphide at 0° and kept in a closed vessel at 50° for 72 hours. Addition of a small amount of water effected separation of the hexoamide (1.25 g.; m. p. 90°), which crystallised from aqueous methyl alcohol in colourless leaves, m. p. 94–96° (Found: N, 11.4; S, 12.4. $C_{11}H_{19}ON_2S$ requires N, 11.2; S, 12.8%).

Use of ethanolamine or of sodium or potassium ethoxide as catalyst failed to improve the yield, and accordingly the attempt to prepare the corresponding thiazole derivative was abandoned.

5-Benzamido-*n*-hexoamide Hydrochloride.—A solution of 5-benzamido-*n*-amyl cyanide (10 g.) in chloroform (60 c.c.) and ethyl alcohol (10 c.c.) was saturated at 5° with dry hydrogen chloride, kept at 5° for 24 hours, and evaporated to dryness at ca. 20°, and anhydrous alcohol (50 c.c.), which had previously been saturated at 0° with ammonia, was added. After standing at 5° for 72 hours and then for a further 24 hours at room temperature, a portion of the alcohol was distilled off at reduced pressure, and the residue diluted with dry ether. The oil which separated slowly solidified to a crystalline mass of the hydrochloride (11.5 g.; m. p. 130°); crystallisation from alcohol-ether yielded white prisms, m. p. 132° (Found: N, 15.1; Cl, 13.7. $C_{13}H_{19}ON_2HCl$ requires N, 15.6; Cl, 13.2%). All attempts to obtain a pyrimidine derivative by condensation with acetylacetone were unsuccessful.

11-Benzamidothioundecoamide.—Hydrogen sulphide was passed into a solution of 10-benzamido-decyl cyanide (25 g.) in methyl alcohol (125 c.c.) and aqueous ammonia (*d* 0.880; 20 c.c.) until an increase in weight of 10 g. was obtained. The solution was heated in a closed vessel for 7 days at 35°, water (100 c.c.) added, and the precipitate collected and recrystallised from aqueous methyl alcohol, 11-benzamidothioundecoamide (10.5 g.) separating in pale cream needles, m. p. 112° (Found: N, 8.9; S, 10.0. $C_{18}H_{29}ON_2S$ requires N, 8.7; S, 10.0%).

4-Methyl-2-(ω -aminodecyl)thiazole.—A solution of the foregoing amide (10.5 g.) in methyl alcohol (75 c.c.) and pyridine (5.4 c.c.) was refluxed with chloroacetone (4.0 c.c.) for 3 hours. The excess of solvent was distilled off, water (100 c.c.) added to the residue, and the 4-methyl-2-(ω -benzamido-decyl)thiazole (11.5 g.; m. p. 54°) collected; this recrystallised from aqueous methyl alcohol in white plates, m. p. 58–60° (Found: C, 70.1; H, 8.5; N, 7.8; S, 8.6. $C_{21}H_{39}ON_2S$ requires C, 70.4; H, 8.4; N, 7.8; S, 9.0%).

The foregoing crude benzamido-compound (27.3 g.) was refluxed with 10N-hydrochloric acid (273 c.c.) for 12 hours, the mixture chilled, and the benzoic acid filtered off. The filtrate was evaporated to small volume at reduced pressure, diluted with water (200 c.c.), and evaporated to dryness. Addition of 5N-sodium hydroxide to the residue, followed by chloroform extraction and distillation, yielded 4-methyl-2-(ω -aminodecyl)thiazole as a pale yellow oil (10 g.), b. p. 166–170°/0.5 mm. (Found: N, 11.0; S, 12.8. $C_{14}H_{28}N_2S$ requires N, 11.0; S, 12.6%).

4-Methyl-2-(ω -sulphanilamidodecyl)thiazole (No. 1433).—Acetylsulphanilyl chloride (3.2 g.) was added to a stirred mixture of the foregoing base (3.0 g.), sodium hydrogen carbonate (2.0 g.), and 50% aqueous acetone (20 c.c.). After being stirred for $\frac{1}{2}$ hour at room temperature, the mixture was heated on the water-bath for $\frac{1}{2}$ hour, diluted with water (100 c.c.), and the precipitate (5.2 g.; m. p. 102°) collected. Recrystallisation from aqueous methyl alcohol yielded 4-methyl-2-(ω -acetylsulphanilamidodecyl)thiazole in white needles, m. p. 102–104° (Found: N, 8.9; S, 14.2. $C_{22}H_{35}O_2N_2S_2$ requires N, 9.3; S, 14.2%). Deacetylation with 2.5N-sodium hydroxide in 50% aqueous alcohol at the reflux for 1½ hours gave 4-methyl-2-(ω -sulphanilamidodecyl)thiazole, which separated from aqueous methyl alcohol in pale cream prisms, m. p. 108° (Found: N, 10.4; S, 15.8. $C_{20}H_{31}O_2N_2S_2$ requires N, 10.3; S, 15.7%).

The authors thank Mr. H. S. Jefferies, B.Sc., for carrying out the biological tests, Mr. D. Fairbairn for technical assistance, and Mr. N. Virgo for the analyses.

256. Application of Thallium Compounds in Organic Chemistry. Part XI.*

By R. C. MENZIES.

A summary is given of earlier work on the thallium method of alkylating sugars and its more recent extensions. It is pointed out that entry of thallium into carbohydrate molecules, controlled by Purves by varying the sizes of the molecules carrying the ethoxide in solution, can also be controlled by varying the effective size of the thallium atom by anchoring it by attached alkyl groups. A case of methylation by boiling a diethylthallium derivative with methyl iodide is also described.

ALKYLATIONS by reaction between thallous compounds and alkyl iodides were first described by Fear and Menzies (*J.*, 1926, 937), *o*-methoxybenzaldehyde, dimethyl hydroxymethoxy-succinate, and a mixture of trimethyl methylglucosides being obtained from thallous salicylaldehyde, tetrathallium tartrate, and trithallium methylglucoside. Twelve years later Purves and Hudson (*J. Amer. Chem. Soc.*, 1937, 59, 49) methylated by this method α -methyl- and α -benzyl-fructofuranosides, both obtained by them from the uncrystallised mixture of isomeric methylfructofuranosides first prepared by the author (*J.*, 1922, 121, 2238). Later, Hirst, Jones, and others (*J.*, 1938, 497; 1939, 458, 1482, 1867, 1884; 1942, 76; 1946, 506) described the thallation and initial methylation of an arabo-pectic acid complex and a number of vegetable gums, thus altering their solubilities so that methylation could be completed by Purdie's reaction. Hirst and Jones also showed (*J.*, 1938, 1695) that the action of methyl iodide on trithallium methylglucoside gave a mixture of 50% of 2 : 4 : 6-, 36% of 2 : 3 : 6-, 10% of 3 : 4 : 6-, and 4% of 2 : 3 : 4-trimethyl methylglucosides, so that positions 2, 3, 4, and 6 were methylated in 90, 50, 64, and 96% respectively of the whole product, positions 2 and 6 being methylated simultaneously in 86%, but positions 3 and 4 were only methylated together to the extent of 14%.

Purves later (*J. Amer. Chem. Soc.*, 1944, 66, 59) investigated the distribution of amorphous and crystalline material in cellulose by treating it with thallous ethoxide dissolved in organic solvents of different molecular sizes.

Thallation followed by treatment with methyl iodide thus affords a method of initial partial methylation capable of being used in non-aqueous solvents, occasionally applicable where sodium hydroxide and methyl sulphate are ineffectual. Purves and Hudson's preparation of dimethyl methyl- and benzyl-fructosides and Hirst and Jones's preparation of partly methylated methylglucosides indicate that thallation can be controlled and used in the preparation of partly methylated sugars.

These authors have laid stress on results rather than on experimental methods. A recapitulation and extension of published and unpublished observations on the thallous derivatives of some of the more simple sugars and allied substances may therefore be of use.

Treatment of substances containing carboxyl or hydroxyl groups with aqueous thallous hydroxide generally results in replacement of the labile hydrogen by the metal. Where hydroxyl hydrogen is replaced, the metal can be accurately titrated with standard acid; it is also converted into thallous carbonate by passing carbon dioxide through the solution. The first compound described in which both replacements occur in the same molecule was tetrathallium tartrate (Part II). Hexathallium gluconate in which five of the six metallic atoms can be titrated was described in Part IV. *Tetrathallium mesotartrate*, *dithallium glycollate*, and *dithallium lactate* are described below. *Trithallium glycerol* and *tetrathallium erythritol* are both sparingly soluble, separating slowly on mixing solutions of the parent compound with aqueous thallous hydroxide. Hexathallium sorbitol was described in Part IV. Many of these and other thallium compounds crystallise well (cf. *Nature*, 1931, 907) so the recognisable patterns formed by mixing drops of the reacting solutions or on allowing their hot solutions to cool on a microscope slide are suitable for identification purposes. So far as is known all hydroxyl hydrogen atoms in straight-chain compounds can be substituted by the metal. When, however, the compound contains a pyranose, furanose, or an attached benzene ring, substitution may be incomplete. For instance, methylarabinoside (Part IV) gives a trithallium derivative, but so, under similar conditions, does methylglucoside (Part III). Sucrose, with eight hydroxyl groups, and salicin, with five, give *tetrathallium sucrose* and *trithallium salicin*. It is only in

* Previous parts of this series published in the *Journal* are : I, 1924, 125, 1148; II, 1925, 127, 2369; III, 1926, 937; IV, 1928, 186; V, 1930, 1571; VI, 1931, 2239; VII, 1932, 2604; VIII, 1932, 2734; IX, 1933, 21; X, 1936, 1678.

rings containing an oxygen atom that incomplete thallation has been observed. Inositol, in which all six hydroxyl groups are secondary, forms sparingly soluble *hexathallium inositol*.

Replacement of hydrogen by the metal in certain cases is thus incomplete. Incomplete also may be subsequent replacement of the metal on treatment with methyl iodide. The attempted methylation of tetrathallium tartrate gave, for instance, after 100 hours, a syrup whose methoxyl content indicated that only three of the metallic atoms had reacted (Part III).

The isolation of well-defined thallous derivatives recalls McKenzie's suggestion (*J.*, 1899, **75**, 765) that a possible explanation of methylation by the silver oxide method is the intermediate formation of an unstable silver derivative which subsequently undergoes double decomposition with the alkyl halide (see also Lander, *J.*, 1900, **77**, 747; 1903, **83**, 416); but these intermediate compounds have never been isolated. Many of the thallous compounds are somewhat unstable, but the fact that they can be isolated facilitates more detailed examination of the mechanism of methylation. Both the occasional incomplete thallation and the usual incomplete subsequent methylation are probably partly due to steric hindrance, but this cause does not act alone. There are also to be considered the alkalinity of the metal or organo-metallic group, the dissociation constant of each individual labile hydrogen, the co-ordinating capacity of the metal, and the presence or absence of water, small amounts being occasionally of importance. Information on the above, and reciprocally, on the properties of the sugars, can be obtained by considering the courses of different methods of substitution on the same, and of the same method on different, hydroxyl compounds.

Steric hindrance certainly plays a part. Purves, for instance, has shown that the depth of entry of thallous ethoxide into fibres of cellulose depends, in the case of the ethers, on the lengths of the carbon chains attached to the oxygen of the ethers. Maxted (*J.*, 1937, 1004) showed that the catalytic activity of platinum in hydrogenations is inhibited by alkyl sulphides in proportion to the lengths of the carbon chains attached to the sulphur. The alkyl groups act like umbrellas. Similar protection of derivatives of β -diketones from hydrolysis, increasing with the length of the alkyl groups attached to the metal, was described in Part X (*loc. cit.*, p. 1880). The probable similar mechanism in this case also is made clear by Powell and Crowfoot's observation (*Z. Krist.*, 1934, **87**, 370) that the alkyl groups in the dialkylthallous compounds are attached at an angle of 180° . The effective size of the thallous atom may thus be increased in a known way without destroying, but not without altering, its power of replacing labile hydrogen, Berry, Lowry, and Gilbert (*J.*, 1928, 1761) having shown that the dialkylthallonium ions are derived from relatively weak bases. One dialkylthallium group probably does not differ much from another in basicity, so that differences between homologous organometallic derivatives may be mainly of steric origin. The non-alkylated metal, however, is a stronger base. It is shown below that in alkaline solutions, where all four labile hydrogen atoms of tartaric acid are replaced by the metal, only three are replaced by the dialkylthallium group. This difference is probably due to both the two causes indicated above. Both causes are also probably concerned in Brady and Hughes's results. They described both mono- and di-thalliumdiphenol, but only mono(diethylthallium)diphenol (*J.*, 1933, 1228). Whatever the cause and whatever alkylation method be used, it is always the insertion of the last group that is the most difficult. Even the silver oxide method occasionally breaks down. Purdie and Young, for instance (*J.*, 1910, **97**, 1524), found that the 3 : 4-dimethyl ether of 2 : 5-dimethylhexane-2 : 3 : 4 : 5-tetraol resisted methylation in this way. McKenzie and Wren (*J.*, 1910, **97**, 473) could only methylate the secondary hydroxyl group of triphenylethylene glycol by its means. Other methods break down more easily. Both the methyl sulphate (Haworth, *J.*, 1915, **107**, 15) and the thallium method (Part III) give incomplete methylation when applied to tartaric acid; and Schlubach and Firgau (*Ber.*, 1926, **59**, 2100) found that, although the potassium salt of 2 : 3 : 6-trimethyl β -methylglucoside gave an 86% yield of tetramethyl β -methylglucoside on treatment with methyl iodide, yet it was unaffected by propyl iodide, benzyl chloride, or acetobromoglucose. The smaller the metal atom or the entering group, and the looser the structure of the metallic derivative, as in Hirst and Jones's preparations of partly methylated methylglucosides and methylarabinosides referred to above, or in Percival's preparation of acetylated trimethyl sucrose (*J.*, 1935, 648), the more likely is substitution of the metal to be complete.

With regard to the varying dissociation of hydrogen from one sugar to another, it is difficult to explain that while the thallation of hexahydroxy-alcohols takes place instantly, that of glycerol and of erythritol takes hours, the solubilities of the resulting thallated derivatives being of the same order, on any other ground than that the lower alcohols must have smaller dissociation constants.

It will also be recalled that the silver oxide method began from following up Purdie and

Pitkeathly's observation (*J.*, 1899, **75**, 153) that in the course of preparation of esters by the action of alkyl halides on silver salts certain anomalous results were encountered, the tartaric esters obtained having abnormally high rotations, and it was ascertained that alkoxy-derivatives were produced during the reaction; *i.e.*, the substitution of silver, known to have a high capacity for forming co-ordination compounds, took place not only on the acid but also on the neighbouring hydroxyl group. This makes it difficult to believe, without further proof, that the replacement of thallium, also a readily co-ordinating element, by other groups always takes place on the same oxygen atom as that to which the metal was attached before reaction with the alkylating agent.

The incomplete thallation referred to above varies in some cases with quite small differences in the conditions of preparation, so that exact repetition of analytical results is occasionally difficult. This difficulty was encountered by Assat, Haas, and Purves (*J. Amer. Chem. Soc.*, 1944, **66**, 61). It is also met with in the analyses of derivatives of sucrose and cellulose and in those of ethylene glycol and of pentaerythritol. In the last two cases the solubility of the derivatives is of the same order as that of thallous hydroxide, and the analyses suggest that both the derivatives of the polyhydric primary alcohols and thallous hydroxide crystallise together. It is important to make clear that these analytical inexactitudes are due, not to the difficulty of determining the metal or of determining carbon or hydrogen in its presence, but, as explained below, to the reactive nature of the components of the molecule of which it now forms a part. Inspection of the analytical results given below and in the earlier numbers of this series will show that: (1) Carbon and hydrogen estimations are not interfered with by the presence of thallium. (2) Thallous salts of organic acids analyse well: occasional high hydrogen values suggest the presence of water of crystallisation. (3) The hydrogen values for chelate thallous compounds are usually good, but irregular carbon figures suggest the presence of thallous salts resulting from hydrolysis. (4) The percentages found for all three elements in chelate compounds of dialkylthallium are usually very good. This is associated with considerable stability. Like platinum catalyst poisons after Maxted has rendered them harmless (*J.*, 1940, 252), all the electronic shells round all the constituent atoms have been completed, and they no longer attract or are attracted by other molecules as much as those in which this is not the case. This is *mutatis mutandis* the Cambridge conception of the survival of the unattractive (Thomson, *Phil. Mag.*, 1921, **41**, 530) and their stability clearly marks the end-points of the reactions leading to their formation. This is, however, not so well marked with the thallous derivatives of the sugars. The sugars are easily oxidised, and univalent thallium is not only easily reduced to the metal but is also easily oxidised to the tervalent state, and is thus an oxygen carrier. Any thallous derivative of the sugars is thus liable to change, and it may change, if care be not taken, under the conditions of preparation. This instability makes them difficult to analyse as accurately as might be wished, but it also makes them useful synthetic agents.

EXPERIMENTAL.

Thallous Derivatives of Hydroxy-acids.—On adding *N*-thallous or -potassium hydroxide to *N*-solutions of tartaric or mesotartaric acid, the precipitation of the acid salt followed by the formation of the normal salt, which dissolves, follows the same course with both alkalis up to the point of neutrality (phenolphthalein). Here the resemblance ends. The first drop of thallous hydroxide in excess leads to precipitation of tetrathallium tartrate (Part II) or of *tetrathallium mesotartrate*, heavy white compact crystals, sparingly soluble and slowly darkened by light [Found: Tl (by titration), 42.41. $C_4H_2O_6Tl_4$ requires Tl, 41.14%].

A few analyses of known thallous tartrates and salts of other carbon acids are here given to illustrate the accuracy to be expected:

	Found.			Calc.		
	C, %.	H, %.	Tl, %.	C, %.	H, %.	Tl, %.
Thallous hydrogen mesotartrate, $C_4H_2O_6Tl$	13.9	1.7	—	13.6	1.4	—
Thallous tartrate, $C_4H_4O_6Tl_2$	8.9	0.85	73.2	8.6	0.7	73.4
Tetrathallium tartrate, $C_4H_2O_6Tl_4$	5.06	0.4	42.65 * 84.6 †	5.0	0.2	42.4 * 84.9 †
Thallous carbonate, Tl_2CO_3 :

* By titration.

† As iodide.

Although these results conform to the usually accepted standards of accuracy, it will be seen that where the molecular weights of normal and tetrathallium tartrates, for instance, are 556.8 and 963.6 respectively, they are inadequate to indicate the presence or absence of small quantities of water of crystallisation, probably influencing, as mentioned above, the course of alkylations. It may be mentioned in this connection that thallium hydrogen *d*-tartrate is described in the literature as anhydrous, while the *mesotartrate* is said to crystallise as a hemihydrate. In alkaline solution the behaviour of the metal resembles that of lead and antimony. The resemblance between tetrathallium and a double tartrate of thallium and antimony has already been pointed out in Part II (p. 2369), and comparison may also be made with a basic lead tartrate $\text{Pb}_2\text{C}_4\text{H}_2\text{O}_6\cdot\text{H}_2\text{O}$ (Beilstein's "Handbuch", Vol. 3, p. 501).

Dithallium glycolate. Glycollic acid was neutralised by thallous hydroxide solution, and a further equal volume was then added. Compact colourless crystals of *dithallium glycolate* slowly separated, resembling, but more soluble than, tetrathallium tartrates, and like them, darkened by light [Found: Tl (by titration), 42.1. $\text{C}_2\text{H}_2\text{O}_3\text{Tl}_2$ requires Tl, 42.4%].

From a solution of glycollic acid accurately neutralised with thallous hydroxide (phenolphthalein) were obtained on evaporation needles of the very soluble normal salt described by Fahlberg (*J. pr. Chem.*, 1873, 7, 339). From a solution of lactic acid neutralised with thallous hydroxide a colourless syrup was obtained on evaporation, which did not crystallise; but on evaporating a solution to which twice the amount of hydroxide necessary for neutralisation had been added, as above, *dithallium lactate* slowly separated on nucleation with a sample obtained by rapid evaporation in a test-tube, in large, highly refracting, colourless crystals [Found: C, 7.6, 7.8; H, 0.91, 1.03; Tl (by titration), 39.4. $\text{C}_2\text{H}_2\text{O}_3\text{Tl}_2$ requires C, 7.25; H, 0.8; Tl, 41.15. $\text{C}_3\text{H}_4\text{O}_4\text{Tl}_2\cdot\text{H}_2\text{O}$ requires C, 7.0; H, 1.2; Tl, 39.7%].

The above basic salts are all colourless. Yellow hexathallium gluconate was described in Part III (p. 189). Saccharic acid also gives a substance approximating in composition to hexathallium saccharate, the way to which lies through *thallium hydrogen saccharate*, now described.

Crude brown potassium hydrogen saccharate (19 g.) was dissolved in water and partly neutralised with thallous hydroxide. The dark brown liquid was then boiled with animal charcoal, and considerable excess of thallous hydroxide added to the almost colourless filtrate. The solution was then made slightly acid with acetic acid, and again boiled with animal charcoal, filtered hot, and cooled. Crude thallium hydrogen saccharate (14.8 g.) separated, which probably contained a little potassium, as the titration value corresponded to 101.3% of thallium hydrogen saccharate. After recrystallisation from hot water, however, 2.126 g. required 5.11 c.c. of *N*-thallous hydroxide (calc., 5.14 c.c.), indicating 99.4% purity (Found: C, 18.3; H, 2.3. $\text{C}_6\text{H}_8\text{O}_7\text{Tl}$ requires C, 17.4; H, 2.2%). The neutral solution obtained by titration gave a glass on evaporation to dryness, thus resembling the normal lactate and also recalling Hirst and Purves's attempt to prepare normal thallium *xylotrimethoxyglutaric acid* (*J.*, 1923, 123, 1358). The syrup was then redissolved, and on the addition of four further equivalents of thallous hydroxide an amorphous yellow precipitate came down, more being obtained by adding alcohol to the filtrate. These on titration showed 52.24% and 50.74% of thallium, respectively. Hexathallium saccharate should contain 85.74% of thallium of which two-thirds or 57.16% should be titratable. It is possible that, on the lines indicated in Part III for the similar yellow hexathallium compounds of gluconic acid and of sorbitol, better analytical results could be obtained. But it is already evident that again the close resemblance between thallous and potassium salts in neutral or acid solutions persists. On making the solution alkaline with thallous hydroxide, more sparingly soluble substances are formed. From hydroxy-acids containing 2, 3, and 4 carbon atoms, these are colourless. From acids and alcohols containing 6 carbon atoms they are yellow. As will be seen below, this yellow colour already appears in the derivatives of ethylene glycol and of glycerol. (Solid TlOH is also yellow.)

Normal *thallous mucate* is easily prepared by neutralising the acid. It is sparingly soluble but can be crystallised from hot water. Its analysis is a good example of the general rule that the more sparingly soluble an organic thallium salt is the better does it analyse (Found: C, 11.8; H, 1.35. $\text{C}_6\text{H}_8\text{O}_7\text{Tl}_2$ requires C, 11.7; H, 1.3%).

Thallous Derivatives of Polyhydric Alcohols.—Sparingly soluble, of definite composition, yellow and darkened by light are *trithallium glycerol* and *tetrathallium erythritol*. A typical preparation is the following. Tetrathallium erythritol (51.1 g., 71.6%) crystallised after some hours' standing from a solution containing erythritol (9.3 g.), 6*N*-thallous formate (50 c.c.), 6*N*-sodium hydroxide (50 c.c.) and water (150 c.c.) (Found: C, 5.10; H, 0.76; Tl, 87.0. $\text{C}_4\text{H}_8\text{O}_4\text{Tl}_4$ requires C, 5.13; H, 0.65; Tl, 87.4%). The *glycerol* compound was prepared similarly (Found: C, 5.18; H, 0.70; Tl, 87.7. $\text{C}_3\text{H}_8\text{O}_3\text{Tl}_3$ requires C, 5.18; H, 0.72; Tl, 87.3%).

Thallium compounds of ethylene glycol. De Forcrand (*Compt. rend.*, 1923, 176, 20) described monothallium ethylene glycol prepared from thallous ethoxide and ethylene glycol as a beautiful precipitate closely resembling dehydrated uranium nitrate. He prepared the glycerol derivative, $\text{C}_3\text{H}_8(\text{OH})_2\text{OTl}$, similarly but did not report analyses. Chablay (*Ann. Chim.*, 1917, 8, 185) prepared dithallium ethylene glycol from monosodium ethylene glycol and thallous nitrate, both dissolved in liquid ammonia. According to him, monothallium ethylene glycol is first formed, 2 mols. of which interact with formation of ethylene glycol and the disubstituted compound. Chablay noted that the compound is soluble in water and that the metal can be determined by titration. He also described a dithallium mannitol made in the same way. Several preparations have now been made of a yellow substance crystallising from weighed quantities of ethylene glycol dissolved in equivalent amounts of aqueous thallous hydroxide. From 2*N*-solutions yellow crystals were obtained, the mother-liquor from which was 0.92*N* at room temperature. Analyses indicated that they were a mixture of approximately 2 mols. of dithallium ethylene glycol with 1 mol. of thallous hydroxide [Found: C, 4.14, 4.00, 3.80; H, 0.95, 0.94, 0.85; Tl, 87.7, 88.7. Calc. for $\text{C}_2\text{H}_4\text{O}_2\text{Tl}_2$: C, 5.12; H, 0.86; Tl, 87.2. Calc. for TlOH : C, 0; H, 0.45; Tl, 92.3. Calc. for $2(\text{C}_2\text{H}_4\text{O}_2\text{Tl}_2)\cdot\text{TlOH}$: C, 4.17; H, 0.79; Tl, 88.9. Calc. for $2(\text{C}_2\text{H}_4\text{O}_2\text{Tl}_2)\cdot\text{TlOH}\cdot\text{H}_2\text{O}$: C, 4.11; H, 0.95; Tl, 87.5%].

Similar results were obtained with pentaerythritol. This alcohol (6 g.) was dissolved in water (20 c.c.) and filtered hot, and thallous ethoxide (44.6 g.; 1 equiv. for each hydroxyl group) was also dissolved in water (60 c.c.), boiled, and filtered hot; on being mixed, the solution became yellow, and, on cooling,

crystals having the appearance of those of thallous hydroxide separated. The whole was then boiled down to half bulk. On cooling, a heavy, yellow, sandy powder separated which adhered firmly to the sides of the flask. This was separated with some difficulty and filtered through a weighed Gooch crucible, washed with alcohol and ether, and dried in a vacuum over phosphoric oxide for 24 hours (Substance A; 18.65 g.) [Found: C, 4.67; H, 0.9; Tl 86.96. Calc. for $C_6H_8O_4Tl_4$: C, 6.32; H, 0.85; Tl, 86.1. Calc. for $C_6H_8O_4Tl_4 \cdot TiOH \cdot H_2O$: C, 5.05; H, 0.93; Tl, 86.0%]. A further 8.5 g. were similarly obtained by adding alcohol to the filtrate (Substance B) [Found: C, 4.82; H, 0.93; Tl (titration), 86.09; Tl (iodide), 87.65%]. The substance obtained from ethylene glycol is thus slightly less soluble than thallous hydroxide, and that from pentaerythritol slightly more soluble. All three solubilities are of the same order, and both alcoholic derivatives appear to form mixed crystals with the hydroxide.

Dithallium trimethylene glycol (23 g.; 95.3%) was obtained as a light yellow precipitate on adding thallous ethoxide (25 g.) in ether to trimethylene glycol (3.8 g.). It was soluble in water but not in benzene (Found: C, 7.61; H, 1.50; Tl, 84.2. $C_3H_8O_3Tl_2$ requires C, 7.46; H, 1.25; Tl, 84.7%).

The thallous derivatives of the hexahydric alcohols resemble those of the di-, tri-, and tetra-hydric alcohols in being yellow and coloured more deeply by light. They differ from them in that they are precipitated instantly on mixing the respective solutions and in being amorphous.

From mixed 2N-solutions containing approximately 1 equiv. of thallous hydroxide for each hydroxyl group of inositol (m. p. 225°) a heavy yellow precipitate of *hexathallium inositol* was obtained [Found: Tl (titration), 87.36. $C_6H_8O_6Tl_6$ requires Tl, 87.6%. $C_6H_8O_6Tl_6$ requires Tl, 85.37%. $C_6H_8O_6Tl_6$ requires Tl, 82.11%]. On adding a slight excess of N-sodium hydroxide to the solution resulting from the above titration a similar yellow solid separated [Found: Tl (titration), 83.5%]. From N-solution the replacement of hydrogen by thallium is not so complete (Found, for precipitate from inositol and 1.1 equivs. of TiOH for each hydroxyl group: C, 5.62; H, 0.58; Tl, 85.75. $C_6H_8O_6Tl_6$ requires C, 5.614; H, 0.43; Tl, 87.6%. $C_6H_8O_6Tl_6$ requires C, 6.01; H, 0.58; Tl, 85.37%).

Inositol has no terminal groups which can be oxidised, and of 0.0298 equiv. of thallous hydroxide taken in this last experiment 0.0297 equiv. was accounted for by titration of the solid and of the mother-liquor. In a comparative experiment using glucose and working in the cold, 7.4% of the titratable thallium disappeared, having been neutralised by acid products of oxidation.

From mannitol and dulcitol and 1 equiv. of thallous hydroxide for each hydroxyl group in approximately 1.3N-solution, yellow derivatives were obtained containing 85.94 and 84.05% thallium respectively by titration ($C_6H_{12}O_6Tl_6$, $C_6H_{10}O_6Tl_6$, and $C_6H_{10}O_6Tl_6$ require respectively Tl, 87.45, 85.23, and 82.11%). The dulcitol compound is coloured brown by light: the inositol compound is turned black. Of the three, the mannitol compound is least changed in colour by light.

The above observations suggest that the thallous derivatives of secondary polyhydric alcohols tend to be less soluble than those of primary, that in the more sparingly soluble derivatives replacement of hydroxyl hydrogen by the metal occurs, but that in cases where the solubility is of the same order as that of the hydroxide addition of thallous hydroxide and of water also takes place. In addition to this, as pointed out on p. 1378, complete substitution of hydrogen by the metal does not always occur from aqueous solutions in more complicated molecules. The derivatives of sucrose, a disaccharide containing eight hydroxyl groups, of which three are primary, and of salicin, a phenolic glucoside containing five hydroxyl groups of which two are primary, are now discussed in the light of the above remarks.

(i) A typical preparation of the *thallous* derivative of sucrose is the following. Sucrose (8.8 g.) was dissolved in water (8 c.c.), cooled, and mixed with 1.275N-aqueous thallous hydroxide solution (68.5 c.c.), i.e., 5 equivs. per mol. of sucrose. After about 2 minutes the mixture became cloudy, and after an hour the white solid separating was filtered off at the pump and kept on a tile in a vacuum over sulphuric acid, taking 4 days to attain constant weight (22.5 g.) [Found: Tl (titration), 70.7; Tl (as iodide), 71.6. $C_{12}H_{22}O_{11}Tl_4$ requires Tl, 70.7%]. On drying, the solid turned yellow. A sample of thallous hydroxide placed in a dry tube at 100° turns black owing to formation of thallous oxide (Tl_2O), whilst the colour of the sucrose compound is unchanged by this treatment.

Preparations carried out with 4 equivs. of the hydroxide to one of sucrose gave substances of similar appearance but of slightly lower thallium content. For instance, 284.6 g. (yield 71.7%) [Found: Tl (titration), 69.9; Tl (as iodide), 68.7%] were obtained from 117.4 g. of sucrose and 4 equivs. of 1.26N-thallous hydroxide. Higher proportions of the hydroxide did not give rise to a corresponding increase of the thallium content, for on treating sucrose with 8 equivs. followed by slow evaporation in a vacuum the first crop separating contained 71.2% of thallium, determined as iodide. The carbon percentages, however, were low and those for hydrogen high. A nearer approach to the observed percentages is afforded by the formula $(C_{12}H_{20}O_{11}Tl_3)_2 \cdot 3TiOH \cdot H_2O$ or $(C_{12}H_{20}O_{11}Tl_3)_2 \cdot TiOH \cdot 3H_2O$, both adding up to $C_{24}H_{40}O_{22}Tl_6$, which requires C, 11.13; H, 1.67; Tl, 71.5% (Found, for two typical samples: C, 11.14, 11.57; H, 1.98, 1.78; Tl, 70.7, 71.6%) and both similar to the results found for the derivatives of ethylene glycol and pentaerythritol.

It is of interest to compare these results with those of Mackenzie and Quin (J., 1929, 951) and of Percival (J., 1935, 648).

(ii) Salicin (3 g.) and thallium hydroxide crystals (9 g.; 3.9 equivs.) were dissolved separately in water, and the solutions mixed and heated; on cooling and addition of alcohol, 7.5 g. of a light yellow substance separated (Found: C, 17.27; H, 1.99; Tl, 64.2%). On evaporation of the solution in a vacuum desiccator, white crystals separated which turned yellow on drying (Found: C, 17.27; H, 1.92; Tl, 63.6%). The mother-liquor yielded a white precipitate on addition of alcohol. These also turned yellow on drying (Found: C, 16.87; H, 1.94; Tl, 63.2. $C_{12}H_{18}O_7Tl_2$ requires C, 17.4; H, 1.65; Tl, 68.4%. $C_{12}H_{18}O_7Tl_2 \cdot 2H_2O$ requires C, 16.73; H, 2.05; Tl, 65.8%).

Surgical cotton-wool (1.71 g., dried over phosphoric oxide. Found: C, 42.7; H, 6.18. Calc. for cellulose: C, 44.44; H, 6.18%) was placed in 1.52N-thallous hydroxide solution and left for 24 hours. The product was then washed repeatedly with alcohol, which converts excess thallous hydroxide into the ethoxide which then dissolves in the alcohol. The product was unchanged in appearance but became yellow on drying, when it weighed 8.24 g. [Found: C, 9.58; H, 1.41; Tl (titration), 73.1;

Tl (as iodide), 75.3%]. In another experiment 4.35 g. of the same cotton-wool were boiled with 1.52N-thallous hydroxide for 15 minutes, washed with alcohol, and dried as before. The dried product weighed 17.36 g. [Found: C, 11.29; H, 1.67; Tl (titration), 63.5; Tl (as iodide), 72.4. Dithallium cellulose requires C, 12.66; H, 1.41; Tl, 71.88%. Trithallium cellulose requires C, 9.32; H, 0.91; Tl, 79.41%. $(C_6H_8O_5Tl_2)_2 \cdot 10H_2O$ requires C, 10.3; H, 1.52; Tl, 73.25%]. In view of the uncertain composition of the cotton-wool used, these results cannot be considered as more than indicating a possible point of departure with pure cellulose should this ever prove to be obtainable.

The basic thallous compounds described above are to be classified as salts, for they are, in the main, insoluble in non-hydrolytic solvents and soluble in water; they are also likely to char on heating without melting (cf. Sidgwick and Brewer, *J.*, 1925, 127, 2379). Thallous methoxide is intermediate. The thallous derivatives of the other normal primary alcohols have definite m. p.s and are more soluble in organic solvents than in water. The basic salts described, however, do resemble many chelate compounds in being stable to alkalis. This property is shared by acetals, and, as was described in Part X, several of the dialkylthallium derivatives of β -diketones are volatile in steam from alkaline solutions. This took place much more easily with the derivatives of dipropionylmethane than with those of acetylacetone. Further, beryllium dipropionylmethane (see below) is volatile in steam in the presence of a little ammonia while beryllium acetylacetone is not. It is not clear whether these facts are really connected.

Beryllium dipropionylmethane is readily made by heating beryllia with the diketone in benzene until the distillate is clear, filtering the residue from excess of beryllia, distilling off the benzene, and finally distilling the residue in a water-pump vacuum; m. p. 63° (Found: C, 62.5; H, 8.46. Found, after distillation in steam, and drying: C, 61.9; H, 8.4. $C_{14}H_{22}O_4Be$ requires C, 63.8; H, 8.4%). It closely resembles beryllium acetylacetone, but is inconveniently soluble in ether, and is better recrystallised from ligroin. On boiling with water containing a little ammonia it distills with the steam essentially unchanged. This does not happen with beryllium acetylacetone.

Action of Air, Light, and Moisture on Thallous Derivatives of Cotton-wool, Salicin, and Sucrose. (Adapted from a report by E. R. WILTSHIRE.)—The observation that the yellow colour of these compounds either appeared on or was intensified by drying led to an examination of the effect of exposing them to a moist atmosphere. Light caused darkening of the first compound. The experiments were therefore carried out by leaving the substances over water in closed vessels in the dark. In each case the yellow colour was gradually lost. As many of the dialkylthallium derivatives are lighter in colour than the corresponding derivatives of the non-alkylated metal, it is reasonable to suppose that this loss of colour is due to the attachment of water to the metal. The precipitate, for example, obtained by passing hydrogen sulphide through a solution of a thallous salt is black, but a white precipitate is obtained from dialkylthallous salts. No information, however, as to the existence of definite hydrates could be obtained from the increase of weight, as the absorption of water appeared to continue indefinitely. After one month the three derivatives gained 44, 58, and 18%, respectively.

A similar experiment was then carried out with a thallium derivative of more definite composition. Thallous fumarate gained the equivalent of 1 mol. of water after 50 days and of 2 mols. after three months. Diethylthallium fumarate gained 3% in 23 days, 1 mol. of water corresponding to 2.4%. In Part II it was shown that thallous 2-methylpyridine-3:4:6-tricarboxylate gained the equivalent of 1 mol. of water in 6 days, after which the weight became constant.

Exposure of thallium derivatives to a moist atmosphere. In each case, a weighed amount of the substance was placed on a watch-glass in a receptacle containing water in the dark:

A.	Thallium cellulose.	Thallium salicin.	Thallium sucrose.
Original wt., g.	0.823	0.517	1.967
Increase after 1 month, g.	0.366	0.302	0.358
" " 1 month, %	44.47	58.4	18.2

The colour in each case gradually disappeared, and finally darkening began to take place. None of the substances came to constant weight.

B.	Thallous fumarate.		Diethylthallium fumarate.	
	G.	%.	G.	%.
Original weight	6.617	—	0.599	—
Increase in wt. after 20 days	0.144	2.2	0.017	3.0
" " " 50 "	0.219	3.3	—	—
" " " 3 months	0.452	5.8	—	—
Calc. for addition of 1 mol. of H_2O	—	3.45	—	2.4

Constant weight was not obtained, but in each case exposure to the atmosphere quickly caused reversion to the original weight.

Dimethyl- (Found: C, 16.32; H, 2.46. Calc. for $C_8H_{14}O_4Tl_2$: C, 16.46; H, 2.42%) and diethylthallium fumarates (Found: C, 22.58; H, 3.37. Calc. for $C_{12}H_{22}O_4Tl_2$: C, 22.6; H, 3.48%) were prepared respectively in 52 and 56% yields by double decomposition between thallous fumarate and the dialkylthallium iodide in boiling water.

The Dialkylthallium Tartrates.—These can be prepared by neutralising tartaric acid with aqueous solutions of the dialkylthallium hydroxides. 4.196 G. of tartaric acid are theoretically required to neutralise 235 c.c. of 0.238N-diethylthallium hydroxide: the weight required lay between 4.1 and 4.19 g. The solution was filtered and evaporated to small bulk on the water-bath. The compound is very soluble in water. On concentration, four crops were obtained: (1) 3.1 g., (2) 6.95 g. on concentrating the aqueous solution. On adding methyl alcohol to the filtrate from crop (2), 3.7 g. were obtained

(crop 3), and finally 2.5 g. on evaporating to dryness (crop 4). Crops 2 and 3 were analysed (Found, respectively: C, 22.4, 19.2; H, 3.17, 3.35. Calc. for $C_{12}H_{24}O_6Tl_2$: C, 21.58; H, 3.63%).

Treatment of diethylthallium tartrate with methyl iodide. 2.63 G. of the tartrate were refluxed with methyl iodide for 17 hours; on removal of the methyl iodide, extraction with ether, filtration, and evaporation of the ether, 0.48 g. of syrup was obtained together with 2.9 g. of colourless diethylthallium iodide, corresponding to 58.3% of thallium in the diethylthallium tartrate taken (Calc.: Tl, 61.3%). As this was evidence that the methylation did proceed, the preparation was then repeated with 11.7 g. of the tartrate. A syrup was obtained which was distilled in a water-pump vacuum; the distillate solidified on nucleation with an authentic sample of dimethyl tartrate (Found: C, 40.85; H, 5.72. Calc.: C, 40.45; H, 5.52%).

Dipropylthallium tartrate. This can be prepared from normal thallous tartrate and dipropylthallium bromide by boiling them together with water. The substance (Found: C, 27.13; H, 4.42. $C_{18}H_{36}O_6Tl_2$ requires C, 26.34; H, 4.42%) is very soluble both in water and in benzene. Probably connected with this is the fact that on evaporating an aqueous solution on a water-bath, crystallisation first begins on the surface of the solution. This also takes place with solutions of diethylthallium tartrate. This surface crystallisation is also characteristic of the dialkylthallium halides, and in their case takes place in a very regular pattern (*Nature*, 1931, 907). The floating crystals are probably visible examples of McBain's ionic micelles.

Attempts to prepare tetrakis-dimethyl- and -diethyl-thallium tartrates by heating tetrathallium tartrate with the respective dialkylthallium halide resulted in the formation of the trisdialkylthallium tartrates only; the incomplete substitution which appears in the thallous compounds of more complicated substances now occurs in the simple tartaric acid molecule, the effective size of the metal having been increased and its strength as an alkali reduced by alkylation.

Treatment of tetrathallium tartrate with dimethylthallium bromide. 4.82 G. (1 equiv.) of the tartrate were boiled with 6.3 g. (4 equivs.) of the bromide. The solution was cooled, filtered from thallous bromide, and concentrated to small bulk. 0.16 G. of sparingly soluble substance, probably unreacted bromide, was filtered off, and then on adding alcohol 2.4 g. of a white precipitate of *trisdimethylthallium tartrate* were obtained [Found (titration): Tl, 22.8. $C_{10}H_{21}O_6Tl_3$ requires Tl (titration), 24.0%]. Another portion, washed with alcohol and acetone and dried in a vacuum, contained Tl, 23.4% (by titration).

Treatment of tetrathallium tartrate with diethylthallium iodide. 12 G. of the tartrate were heated in water with excess of the iodide. Two crops were obtained, containing severally Tl, 20.75, 23.16% (by titration). On addition of potassium iodide to a solution, diethylthallium iodide was recovered corresponding to 66.64% of thallium [*trisdiethylthallium tartrate*, $C_{16}H_{38}O_6Tl_3$, requires Tl (total), 65.63; Tl (by titration), 21.88%].

Part of this work has been carried out by the writer during the last year in Professor Kendall's Department in Edinburgh, whose kindness and hospitality as also that of Dr. Neil Campbell, of Dr. E. G. V. Percival and of everyone else in the department, he wishes gratefully to acknowledge. Part of it also is taken from unpublished notes left in his hands by Miss C. M. Fear and Mr. E. R. Wiltshire.

The writer wishes to thank Professor E. L. Hirst and Dr. E. G. V. Percival for useful criticism.

Acknowledgment is also made to the Colston Society of the University of Bristol for their continuous generosity during a term of fourteen years.

The author also wishes to thank Mr. Gilbert Allen, of Bristol University, who safeguarded his materials and preparations all through the War.

THE UNIVERSITIES OF BRISTOL AND EDINBURGH.

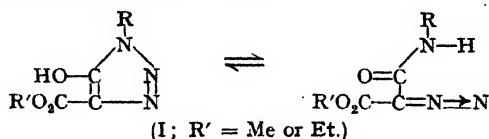

[Received, November 29th, 1946.]

257. *The Mechanism of the Tautomeric Change of 5-Hydroxy-1:2:3-triazole-4-carboxylic Esters into Aliphatic Diazo-compounds.*

By B. R. BROWN and D. LL. HAMMICK.

Dimroth (*Annalen*, 1904, **335**, 1; 1905, **338**, 143; 1910, **373**, 336) interpreted the kinetics of this reaction as showing that the change takes place in the un-ionised enol molecule. A reconsideration of his data indicates that the change is bimolecular, involving a proton and an enol ion. The electronic processes involved in the proposed mechanism are deduced from a comparison of rate constants for various substituted triazole esters.

THE reaction under consideration is the following:

which was established by Dimroth (*loc. cit.*). Owing to the fact that the enolic triazole tautomer is acidic, he was able to study the kinetics of the forward reaction and the equilibrium in various solvents. He interpreted his results as showing that the reaction is unimolecular

with respect to the enol, and concluded that the change from enol to neutral form takes place in the un-ionised enol molecule. His evidence (*Annalen*, 1904, **335**, 60) was the observed proportionality between the rate in the presence of various concentrations of the sodium salt of the enol, and the amount of undissociated enol as calculated from the "degree of dissociation" of the sodium salt obtained from conductivity data. His conclusion is invalid on account both of this fallacious "degree of dissociation", and of the occurrence of an appreciable salt effect.

A reconsideration of Dimroth's results in the light of more recent ionic and kinetic theory shows that the reaction is in reality a bimolecular process involving a hydrogen ion and an enol ion. Thus his values (*ibid.*, p. 53) for the rate constants in the presence of water and of 0.06N-sodium chloride :

$$\begin{aligned} k \text{ (mins.}^{-1}\text{) at } 50^\circ \text{ in water (I; R = phenyl)} &= 0.00128 \\ k \text{ (mins.}^{-1}\text{) at } 50^\circ \text{ in 0.06N-NaCl (I; R = phenyl)} &= 0.00106 \end{aligned}$$

reveal a negative salt effect and indicate that the reaction is between two oppositely charged ions. Also his unimolecular rate constants increase as the concentration of either the hydrogen ion or the enol ion increases (*ibid.*, p. 54) :

$$\begin{aligned} k \text{ (mins.}^{-1}\text{) at } 50^\circ \text{ in water (I; R = phenyl)} &= 0.00128 \\ k \text{ (mins.}^{-1}\text{) at } 50^\circ \text{ in dilute HCl (I; R = phenyl)} &= 0.00195 \end{aligned}$$

Mols. of Na salt of enol : mols. of enol.	k (mins. ⁻¹).
0 : 1	0.00128
1 : 1	0.00195
2 : 1	0.00225
4 : 1	0.00267
8 : 1	0.00306

Addition of alkali causes an increased rate of reaction by increasing the concentration of enol ion. This fact is remarked upon by Dimroth (*ibid.*, p. 3), and prevents an ordinary alkali titration being used to follow the reaction.

Following up this evidence, Dimroth's results (*ibid.*, p. 49) for the tautomerism of (I; R = phenyl) in water have been recalculated using a bimolecular rate equation. His values (*ibid.*, 1905, **338**, 175; 1904, **335**, 57) for the dissociation constant of this compound in water are :

$$\begin{aligned} K \text{ at } 25^\circ &= 1.6 \times 10^{-2} \\ K \text{ at } 50^\circ &= 1.3 \times 10^{-2} \end{aligned}$$

whence the value at 40° is estimated at 1.4×10^{-2} . Using these dissociation constants and the following equations for the estimation of the enol,

the following typical sets of results were calculated :

25 C.c. of reaction mixture titrated against N/50-thiosulphate (temp., 50°).

Time (mins.).	Titre (c.c.).	$[\text{H}^+] = [\text{enol ion}]$ (mols./l.).	Bimol. k (mols./l./sec.).	Dimroth's unimol. constant $0.4343k$ (mins. ⁻¹).
0	18.55	0.884×10^{-2}		
60	17.10	0.834 "	1.88×10^{-3}	5.89×10^{-4}
120	15.85	0.789 "	1.94 "	5.69 "
180	14.68	0.747 "	1.92 "	5.65 "
300	12.62	0.667 "	2.05 "	5.57 "
400	11.13	0.607 "	2.15 "	5.54 "
		Average : 1.99 "		
		Average for a similar set at 50° : 1.88 "		

100 C.c. of reaction mixture titrated against N/10-thiosulphate (temp., 40.2°).

0	12.77	0.809×10^{-2}		
170	12.13	0.779 "	4.67×10^{-4}	1.31×10^{-4}
300	11.70	0.759 "	4.53 "	1.27 "
380	11.47	0.748 "	4.46 "	1.23 "
470	11.15	0.732 "	4.61 "	1.21 "
		Average : 4.57 "		

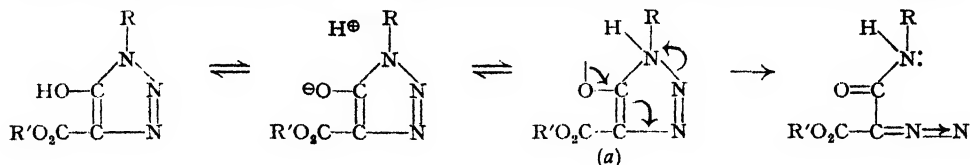

Whence, $k_{50^\circ} = 1.94 \times 10^{-3}$ and $k_{40.2^\circ} = 4.57 \times 10^{-4}$, both in mols./l./sec. Substitution in the equation $k = PZ e^{-E/RT}$ gives the following E and PZ values :

$$E = 29,660 \text{ cal.}$$

$$PZ = 10^{+17.3}$$

It is seen that the PZ value is one normally observed for a reaction between oppositely charged ions, viz., 10^{+13} to 10^{+19} (Bell, *J.*, 1943, 629), and therefore supports a bimolecular ionic mechanism.

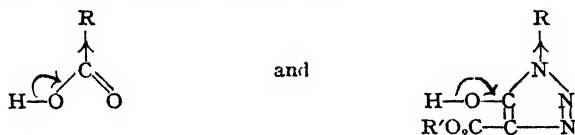

These considerations lead us to suggest the following picture of the tautomeric change :

Evidence that the electronic processes implied in (a) for the decomposition of the transition state are rate-determining is obtained by a consideration of the effects of substituents on the rate constants and on the equilibrium constants. These will be expected to parallel the dissociation constants of the enol, which in turn should parallel the dissociation constants of the corresponding acids, $R \cdot CO_2H$. That the latter is the case is evident from Dimroth's determination of the dissociation constants of various enol forms :

R.	$R \cdot CO_2H$. (Watson, "Modern Theories of Organic Chemistry," 2nd Edition, 1941, p. 27.)	Enol. (Dimroth, <i>Annalen</i> , 1905, 338, 175.)
Methyl	1.82×10^{-5}	0.3×10^{-2}
<i>p</i> -Tolyl	4.24 "	1.0 "
Phenyl	6.27 "	1.6 "
<i>p</i> -Bromophenyl	10.7 "	2.0 "

It is seen that the dissociation constants increase with the power of the group R to accept electrons, as expected for the comparable processes :

The electronic processes (a) in the proposed mechanism should likewise be facilitated by acceptor groups at R , and hence the rate and equilibrium constants (diazo-compound/triazole) should increase in the same order as the ionisation constants, i.e., with the accepting power of R . That this does occur is good evidence for the proposed electron shifts.

Values of K and k in ethyl alcohol at 25° .

(Dimroth, *Annalen*, 1910, 373, 349.)

R.	K .	k (mins. ⁻¹).
Benzyl	118	0.003×10^{-2}
<i>p</i> -Tolyl	120	0.94 "
Phenyl	300	1.02 "
<i>p</i> -Bromophenyl	555	4.58 "
<i>p</i> -Nitrophenyl	very large	60.0 "
2 : 4-Dinitrophenyl	not measurable	100.0 "

Thus Dimroth's kinetic data indicate that the reaction has an ionic mechanism, involving the attack of a proton on an enol ion, and furthermore, enable the nature of the electronic shifts involved to be elucidated with a fair degree of certainty.

We wish to thank Mr. R. P. Bell, F.R.S., for helpful criticism.

258. The Absorption Spectra of 2:4-Dinitrophenylsemicarbazones.

By A. E. GILLAM and D. G. MOSS.

The absorption spectra of new and previously-prepared 2:4-dinitrophenylsemicarbazones of various aldehydes and ketones are recorded and shown to be, approximately, summation curves of the light absorption due to the reagent and that of the chromophore

where $n = 0, 1, 2$, or 3 and R, R' , and R'' may be either H or alkyl. The maxima of the subtraction curves suffer a steady displacement to longer wave-lengths as the conjugated system is lengthened.

IN earlier papers (*J.*, 1940, 1453; 1941, 815; 1943, 565; 1945, 432) light-absorption data on carbon compounds containing specific chromophoric groups such as those of unsaturated ketones and their semicarbazones and similar derivatives were collected and classified with the object, among others, of using the data in the determination of molecular structure. In the present communication the absorption spectra of 2:4-dinitrophenylsemicarbazones of various carbonyl compounds are recorded and an attempt is made to correlate the location of the absorption bands with the structure of the compounds and especially the length of the conjugated system present.

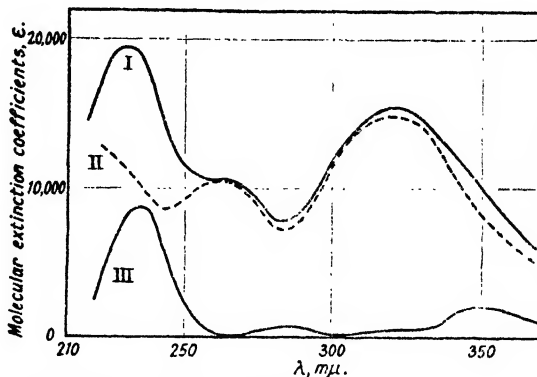

2:4-Dinitrophenylsemicarbazide was first prepared by Kniphorst (*Rec. Trav. chim.*, 1925, **44**, 724) who also showed that it formed condensation products with carbonyl compounds. McVeigh and Rose (*J.*, 1945, 713) have more recently shown that it can be used as a means of detection and characterisation of aldehydes and ketones generally, and have recorded the melting points of a number of derivatives of such compounds.

The molecules of these carbonyl derivatives contain two main chromophoric units, namely 2:4-dinitrophenylsemicarbazide itself and the substituted $>C=N-$ group formed by condensation of the carbonyl group with the active $-NH_2$ group of the semicarbazide. With $\alpha\beta$ -unsaturated ketone derivatives the chromophoric groups are those of the substituted semicarbazide itself and the $CR_2:CH:CR'_2N-$ group which is, in effect, the $-C=C-C=N-$ chromophore normally met with in simple semicarbazones (cf. Evans and Gillam, *J.*, 1943, 565). The work of Ramart-Lucas and her various collaborators (*Bull. Soc. chim.*, 1932, **51**, 289) has shown that in a compound having two unconjugated chromophores the light absorption approximates more nearly to a simple summation the more widely separated are the chromophores in the molecule. Thus in the 2:4-dinitrophenylsemicarbazones of unsaturated carbonyl compounds the two compound chromophores are unconjugated but not widely separated so that complete independence is not to be expected.

If we compare the absorption curves of the substituted semicarbazones of simple ketones with those of the corresponding derivatives of $\alpha\beta$ -unsaturated ketones and of dienones we would further expect to find that the summation curves contain a fixed component (the semicarbazide chromophore) and one which varies in the location of its band with the length of the conjugated system responsible for it. Thus in any observed absorption curve of a 2:4-dinitrophenylsemicarbazone if we subtract the known absorption of the reagent the resulting subtraction curve should be that of the $R-[CR'=CH]_n-CH=N-$ chromophore (where $n = 0, 1, 2, 3$, etc., and R and R' may be either H or alkyl groups).

The numerical data are given in Table I, whilst Figs. 1, 2, and 3 show the absorption curves of only a few of the more typical examples. The occurrence of low-intensity absorption bands between 270 and 360 $m\mu$ in some of the subtraction curves is still unexplained, but this does not appear to affect the main conclusions.

- I. Crotonaldehyde.
- II. 1-Methylcyclohexen-3-one.
- III. 3-Methylpent-3-en-2-one.
- IV. Mesityl oxide.

The subtraction-curve data in Table I show the steady displacement of the maxima to longer wave-lengths as the length of the conjugated system in the non-semicarbazide part of the molecule increases. This is shown more clearly in Fig. 4. The fact that the two types of aromatic carbonyl derivative show displacements which are respectively equivalent to $2\frac{1}{2}$ and $3\frac{1}{2}$ ethylene linkages supports the suggestion of Kuhn, Hütsser, *et al.* (*Z. physikal. Chem.*, 1935, 29, B, 363) that a benzene nucleus in conjugation with one or more ethylene linkages is equivalent to $1\frac{1}{2}$ of such bonds.

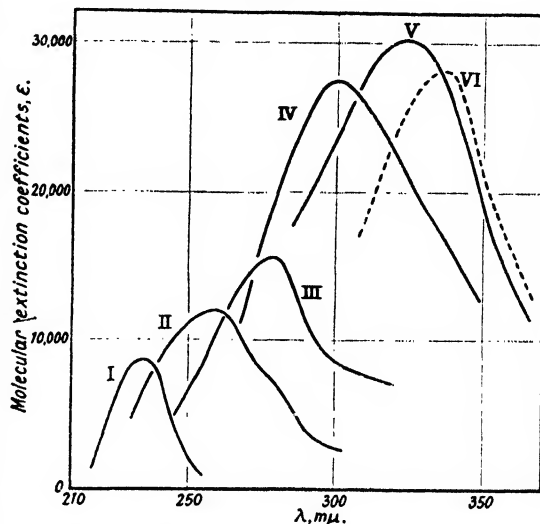

FIG. 3.

Acetophenone	2715	17,780	2650	14,800

corrected for the separate absorption of the reagent itself should yield a subtraction curve comparable with the known and directly observed absorption spectra of the simple semicarbazones. The available data are given in Table II, and, considering the number of variables concerned in obtaining the data, the general agreement is good, being better in terms of location of the band than where intensities are concerned. The values for ψ -ionone are noticeably discrepant in this latter respect.

EXPERIMENTAL.

1-Methylcyclohexen-3-one was prepared by condensation of formaldehyde and acetoacetic ester followed by ring-closure of the methylenediacetoacetic ester (Knoevenagel, *Annalen*, 1894, **281**, 94); b. p. 200°.

3-Methylpent-3-en-2-one was prepared by condensation of acetaldehyde and methyl ethyl ketone (Hinkel, *J.*, 1931, 817). The ketone was crystallised from benzene to constant m. p., but the N content was low (Found: N, 19.6. Calc.: N, 21.8%). This might have been due to retention of solvent as the spectroscopic data were quite normal. Attempted purification by chromatography gave slight evidence of lack of homogeneity, but no increase in purity was in fact achieved.

ψ -Ionone was prepared by condensation of acetone and citral (Stiehl, *J. pr. Chem.*, 1898, **58**, 79) and crystallised successively from chloroform and chlorobenzene.

We are indebted to Dr. E. R. H. Jones for a sample of citrylidene crotonaldehyde which was isolated from the products of the condensation of citral with crotonaldehyde (cf. Batty *et al.*, *J.*, 1937, 756; 1939, 1559). The specimen used had λ_{\max} , 3140 Å.; $\epsilon = 14,500$.

2:4-Dinitrophenylsemicarbazones.—These were prepared by dissolving 2:4-dinitrophenylsemicarbazide (0.5 g.) in alcohol (80 ml.) and adding to the boiling solution slightly less than the theoretical amount of the carbonyl compound dissolved in the minimum of alcohol. After addition of concentrated hydrochloric acid (2 drops) the solution was boiled for ten minutes after which the precipitated derivative was filtered off, being usually only very sparingly soluble in alcohol even at the boiling point. For recrystallisation chloroform was found to be the most useful solvent and derivatives were recrystallised to constant melting point, two or three crystallisations being usually sufficient. All the 2:4-dinitrophenylsemicarbazones in Table III are new except that of methyl ethyl ketone (cf. McVeigh and Rose, *loc. cit.*).

1-Methylcyclohexen-3-one	227.5	C ₁₄ H ₁₆ O ₅ N ₅	21.0	20.7	Chloroform
ψ -Ionone	227	C ₂₀ H ₂₆ O ₅ N ₅	16.9	16.1	Chlorobenzene
Hepta-3:5-dien-2-one	240	C ₁₄ H ₁₄ O ₅ N ₅	21.0	20.4	Alcohol
Citrylidene crotonaldehyde	207 (no decomp.)	C ₂₁ H ₂₅ O ₅ N ₅	16.4	16.1	Alcohol

Absorption spectra were determined by standard methods using a Hilger E3 quartz spectrograph and a Spekker photometer. Purified alcohol was used as solvent throughout, although the very low solubility of the 2:4-dinitrophenylsemicarbazones made this difficult at times. The high intensity of absorption in some cases made it possible to use very dilute solutions for the determination, and the concentrations usually ranged between 0.03 and 0.003% only. The solutions were made by dissolving 2—3 mg. of the compound in hot alcohol, cooling, and making up to suitable volume, e.g., 100 ml. All determinations were made in duplicate, the λ_{\max} and ϵ_{\max} values being taken from the mean curves.

Our thanks are due to Miss McVeigh and Dr. F. L. Rose for specimens of a number of the compounds examined.

THE UNIVERSITY OF MANCHESTER.

[Received, December 19th, 1946.]

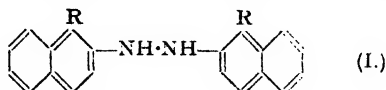

259. The Naphthidine Transformation involving β -Positions only.

By HERBERT H. HODGSON, JOHN HABESHAU, and P. B. R. MURTI.

1:1'-Dichloro- and 1:1'-dibromo-2:2'-diamino-3:3'-dinaphthyl are most probably formed in the reduction of 1:1'-dichloro- and 1:1'-dibromo-2:2'-azonaphthalene by stannous chloride in ethyl alcohol-hydrochloric acid solution. 1-Bromo-2-naphthalenediazoacetate decomposes at ordinary temperatures to give 1-bromo-2-naphthaleneazo- β -naphthol.

THE naphthidine transformations already reported have involved α - and $\alpha\beta$ -positions only (Nietzki and Goll, *Ber.*, 1885, **18**, 3254; Vesely, *Ber.*, 1905, **38**, 136; Meisenheimer and Witte, *Ber.*, 1903, **36**, 4153; Hodgson and Habeshaw, this vol., p. 77). It is of interest also that,

in the transformation of 1 : 1'-hydrazonaphthalene, the 2- and 4-positions exhibit approximately equal activity (cf. Hodgson and Habeshaw, *loc. cit.*) while no mixed 1 : 1'-diamino-2 : 4'-dinaphthyl has ever been detected among the transformation products. No change involving the 2 : 3- (*i.e.*, solely β -positions) transformation has hitherto been reported, and, in view of the fact that among the possible resonance structures of a 1 : 1'-substituted -2 : 2'-hydrazonaphthalene there is one (I) which indicates that such a change might be possible, it appeared of interest

to investigate whether this 2 : 3-naphthidine change would occur in the cases of 1 : 1'-dichloro- and 1 : 1'-dibromo-2 : 2'-hydrazonaphthalenes (I; R = Cl or Br) since such compounds might be formed intermediately by the action of stannous chloride in ethyl alcohol-hydrochloric acid suspensions of 1 : 1'-dichloro- and 1 : 1'-dibromo-2 : 2'-azonaphthalenes (cf. Cohen and Oesper, *Ind. Eng. Chem. Anal.*, 1936, 8, 306).

As anticipated, dinaphthyl formation occurred and in all probability 1 : 1'-dichloro- and 1 : 1'-dibromo-2 : 2'-diamino-3 : 3'-dinaphthyls were formed, so that the naphthidine transformation had taken place between β -positions only. When the reduction of the above halogeno-azo-compounds was carried out with stannous chloride and hydrochloric acid in the absence of ethyl alcohol, cleavage occurred between the nitrogen atoms of the azo-group, and 1-chloro- and 1-bromo-2-naphthylamine were formed respectively. The constitutions of the above dinaphthyls were tentatively established by the fact of dihydrochloride formation in the cases of the chloro- and bromo-compounds, and of the tetrazotisation of the 1 : 1'-dibromo-2 : 2'-diamino-3 : 3'-dinaphthyl and subsequent coupling with alkaline β -naphthol to give a bisazo-compound. Since halogens were not displaced, it is most unlikely that dinaphthyl formation would involve the 4 : 4'-positions.

When a solution of 1-bromo-2-naphthalenediazoacetate was allowed to decompose at ordinary temperatures, 1-bromo-2-naphthaleneazo- β -naphthol was produced, an indication that 1-bromo-2-naphthol must first have been formed, by hydrolysis of the diazoacetate, and that unchanged diazo-compound subsequently coupled with it in the 1-position by displacement of the 1-bromine atom.

EXPERIMENTAL.

1 : 1'-Dichloro-2 : 2'-diamino-3 : 3'-dinaphthyl.—1 : 1'-Dichloro-2 : 2'-azonaphthalene (5 g.) (compare Hodgson, Leigh, and Turner, *J.*, 1942, 744) was boiled gently with ethyl alcohol (50 c.c.) and a solution of crystallised stannous chloride (10 g.) in hydrochloric acid (25 c.c., *d* 1.18) added gradually with shaking. During this addition, all the solid passed into solution, and, after the mixture had been kept on the boiling water-bath for 10 minutes, it was cooled and then treated with hydrochloric acid (25 c.c., *d* 1.18); 1 : 1'-dichloro-2 : 2'-diamino-3 : 3'-dinaphthyl dihydrochloride then separated (1.6 g.) in colourless crystals which were filtered off and washed with ether; it was soluble in water, evolved hydrogen chloride on treatment with concentrated sulphuric acid with formation of a yellow solution, and decomposed on heating at *ca.* 400° (Found : Cl, 33.2. $C_{20}H_{16}N_2Cl_4$ requires Cl, 33.3%).

1 : 1'-Dichloro-2 : 2'-diamino-3 : 3'-dinaphthyl was obtained as a white flocculent precipitate, which coagulated somewhat on standing and became biscuit coloured, when warm aqueous sodium carbonate was stirred into a warm aqueous solution of the above dihydrochloride; it was filtered off, washed, dried, and crystallised from benzene-light petroleum (1 : 1) in small colourless needles, m. p. 121–122° (Found : N, 8.1; Cl, 19.8. $C_{20}H_{14}N_2Cl_2$ requires N, 7.9; Cl, 20.1%), which soon became discoloured in air and was moderately soluble in ethyl alcohol; the alcoholic solution, however, rapidly oxidised and became reddish-violet, a red film forming on the wall of the glass container.

Preparation of 1-Bromo-2-naphthylamine.—A solution of β -naphthylamine (28 g.) in glacial acetic acid (200 c.c.) containing acetic anhydride (25 c.c.) was heated on the boiling water-bath for 20 minutes to complete the acetylation, and then treated dropwise with the theoretical amount of bromine (32 g.) during continuous stirring. The resulting 1-bromoaceto-2-naphthalide was precipitated by dilution with water in quantitative yield, the precipitate dissolved in alcohol (250 c.c.), hydrochloric acid (30 c.c., *d* 1.18) added, and the mixture boiled for 6 hours to complete the hydrolysis; 1-bromo-2-naphthylamine was then precipitated by addition of 20% aqueous sodium hydroxide, purified by crystallisation from light petroleum, and obtained in colourless needles, m. p. 63° (Cosiner, *Ber.*, 1881, 14, 59, gives m. p. 63°) (Found : Br, 35.8. Calc. for $C_{10}H_7NBr$: Br, 36.0%).

1-Bromo-2-naphthaleneazo- β -naphthol, obtained by diazotisation of the above amine and coupling with alkaline β -naphthol in the usual way, crystallised from toluene in dark red parallelepipeds, m. p. 169–170° (Found : N, 7.5; Br, 21.0. $C_{20}H_{13}ON_2Br$ requires N, 7.4; Br, 21.2%), which gave with concentrated sulphuric acid a bright red-violet colour turning to crimson on dilution with water.

1-Bromo-2-naphthaleneazo- β -naphthylamine, obtained by diazotisation of the above amine in aqueous hydrochloric acid and coupling with an alcoholic solution of β -naphthylamine in the presence of acetic acid and sodium acetate (cf. Hodgson and Foster, *J.*, 1941, 755), crystallised from toluene in scarlet plates, m. p. 174–175° (Found : N, 11.3; Br, 20.8. $C_{20}H_{14}N_2Br$ requires N, 11.2; Br, 21.0%), which

gave with concentrated sulphuric acid a blue colour turning to red and then to orange-yellow on addition of water.

1:1'-Dibromo-2:2'-azonaphthalene.—A mixture of finely divided 1-bromo-2-naphthylamine (5 g.) in hydrochloric acid (25 c.c., *d* 1.18) and water (50 c.c.) was diazotised by addition of a solution of sodium nitrite (2 g.) in water (10 c.c.) with stirring at 0°, the resulting yellow solution filtered, treated rapidly under vigorous stirring with crystallised sodium acetate (40 g.) dissolved in the minimum amount of water to remove mineral acid, and then immediately followed by a solution of crystallised sodium sulphite (10 g.) in water (50 c.c.). A light brown precipitate immediately separated (5.7 g.), and after the mixture had been stirred for 30 minutes at room temperature, when no further reaction of the precipitate with alkaline β -naphthol was detected (absence of diazo-sulphite, cf. Hodgson and Marsden, *J.*, 1943, 470), it was heated to 60° and filtered. The precipitate of 1:1'-dibromo-2:2'-azonaphthalene crystallised from benzene in yellow plates, m. p. 193–195° (Found: N, 6.6; Br, 36.2. $C_{10}H_6Br_2N_2$ requires N, 6.4; Br, 36.4%), which gave with concentrated sulphuric acid a Bordeaux-red solution turning to scarlet on addition of water.

When the solution of 1-bromonaphthalenediazonium chloride above was treated with sodium acetate only, 1-bromo-2-naphthaleneazo- β -naphthol separated on keeping; it crystallised from toluene in red parallelepipeds, m. p. and mixed m. p. with authentic specimen 168–170° (Found: N, 7.5; Br, 21.0%). If an inadequate amount of sodium acetate is added before the sodium sulphite, the resulting 1:1'-dibromo-2:2'-azonaphthalene is mixed with the azo- β -naphthol dye above.

1:1'-Dibromo-2:2'-diamino-3:3'-dinaphthyl.—A suspension of 1:1'-dibromo-2:2'-azonaphthalene (5 g.) in ethyl alcohol (50 c.c.) was heated on the boiling water-bath during the gradual addition with vigorous shaking of a solution of crystallised stannous chloride (10 g.) in hydrochloric acid (25 c.c., *d* 1.18), and the boiling continued (30 minutes) until most of the suspended matter had passed into a nearly colourless solution. The mixture was filtered hot, cooled, hydrochloric acid (20 c.c., *d* 1.18) added, the precipitate (*a*) filtered off, and the solution kept; crystals (*b*) of 1:1'-dibromo-2:2'-diamino-3:3'-dinaphthyl dihydrochloride then separated. Crystals (*b*) were filtered off and washed with ether (Found: Ionic Cl, 13.6. $C_{20}H_{14}N_2Br_2 \cdot 2HCl$ requires Cl, 13.8%). Precipitate (*a*) and crystals (*b*) were repeatedly stirred with hydrochloric acid (5 c.c., *d* 1.18) and water (10 c.c.), aqueous sodium nitrite was added until a positive reaction for free nitrous acid was obtained, the mixtures were filtered, and the resulting solutions of 1:1'-dibromo-3:3'-dinaphthyl-2:2'-tetrazonium chlorides were stirred into alkaline β -naphthol; in each case 1:1'-dibromo-3:3'-dinaphthyl-2:2'-bisazo- β -naphthol separated; this compound crystallised from toluene in red micro-plates, m. p. 315° (Found: N, 7.6; Br, 21.1. $C_{40}H_{24}O_2N_4Br_2$ requires N, 7.4; Br, 21.3%), which give a brilliant blue-violet colour with concentrated sulphuric acid.

The dihydrochloride [crystals (*b*) above] was cautiously decomposed with sodium carbonate or ammonia at about 60°, the resulting base crystallised from toluene–light petroleum in minute colourless needles, m. p. 117° (Found: N, 6.5; Br, 36.0. $C_{24}H_{14}N_2Br_2$ requires N, 6.3; Br, 36.2%).

260. *The Replacement of the Diazonium by the Nitro-group. Part III. Decompositions by Cupro-cupri Sulphite.*

By HERBERT H. HODGSON, A. P. MAHADEVAN, and EDWARD R. WARD.

Solid aryldiazonium sulphates are first prepared and their aqueous solutions decomposed by cupro-cupri sulphite suspended in saturated aqueous sodium nitrite, yields up to 65% of nitro-compound being obtained. The precipitate obtained by addition of aqueous sodium sulphite to aqueous copper sulphate appears to be more efficient than the red-violet variety hitherto used. The method is useful for the preparation of rare dinitronaphthalenes of which six examples are given.

THE solid diazonium sulphates obtained by the general method of Hodgson and Mahadevan (this vol., p. 325) are readily decomposed when added either in aqueous solution or in solid form to a saturated solution of sodium nitrite containing cupro-cupri sulphite in suspension (cf. Hantzsch and Blagden, *Ber.*, 1900, 33, 2544; Contardi, *Annali Chim. Appl.*, 1923, 7, 13) to give excellent yields of the corresponding nitro-compounds. In particular, the method has proved to be exceedingly serviceable for obtaining the rarer dinitronaphthalenes in excellent yield and purity, and has also worked satisfactorily with benzidine, 3:3'-dinitrobenzidine, and 3:5-dinitro-*p*-toluidine. The cupro-cupri sulphite used was prepared by the addition of aqueous sodium sulphite to an equivalent amount of aqueous copper sulphate, and the greenish yellow-brown gelatinous precipitate, when washed free from excess of either component, was stirred as a slurry into the saturated aqueous sodium nitrite. So prepared, this variety of cupro-cupri sulphite appeared to be more efficient than the red-violet crystalline precipitate obtained by the addition of aqueous ammonium sulphite saturated with sulphur dioxide to warm aqueous copper sulphate and raising the temperature to 90° for 10 minutes (Mellor, "A Comprehensive Treatise on Inorganic and Theoretical Chemistry", Vol. X, pp. 273–277).

The preparation of some solid diazonium sulphates (e.g., that from 3-nitro-*p*-toluidine) involves the use of minimum amounts of acetic and sulphuric acids, and for this purpose the inverted diazotisation procedure of Hodgson and Walker (cf. Hodgson and Turner, *J.*, 1943, 86) has been used, *viz.*, a solution of the amine in the minimum amount of concentrated sulphuric acid is treated with solid sodium nitrite and the mixture stirred into glacial acetic acid; with 3-nitro- and 3 : 5-dinitro-*p*-toluidine, the temperature could safely be allowed to reach 40° during the addition of the sodium nitrite without loss of yield of the resulting diazonium salt.

Usually, the solid diazonium sulphate, after precipitation by ether from the diazotisation medium, is dissolved in water at 0° before the cupro-cupri sulphite treatment, but it is essential first to remove admixed acid from it by washing with alcohol or ether or both. When these precautions are observed, 2-nitro-1- and 1-nitro-2-naphthylamine, which require the glacial acetic-sulphuric acid method (Hodgson and Walker, *J.*, 1933, 1620) for their diazotisation, afford the respective diazonium sulphates, the former of which readily dissolves in cold water; both form solutions which remain stable for periods of time amply sufficient for the subsequent manipulation. If, instead of first isolating the solid diazonium sulphates, the solutions of these diazonium salts as prepared by the Hodgson and Walker method (*loc. cit.*) are diluted with water and then neutralised before the cupro-cupri sulphite treatment, diazo-oxide formation occurs rapidly and no dinitronaphthalene can be obtained (cf. Veselý and Dvůrák, *Bull. Soc. chim.*, 1923, 33, 319, who failed to obtain 1 : 2-dinitronaphthalene from 1-nitro-2-naphthylamine from this cause).

The co-precipitation of sodium sulphate in almost anhydrous form with the solid diazonium sulphate probably accounts for the separation of the latter in a satisfactory crystalline state free from the stickiness usually encountered in the ordinary mode of diazonium salt isolation, since any water present will be bound by the sodium sulphate.

Addition of solid diazonium sulphate to the decomposition medium is not usually satisfactory, owing to formation of tar, probably because of local overheating during decomposition, while the tendency for hydroxylic by-products (phenols or naphthols as indicated by dissolution in alkalis), or small amounts of azo-compounds (as indicated by colour reactions) is enhanced.

It has been found that aryldiazonium cobaltinitrites (cf. Hodgson and Marsden, *J.*, 1944, 22) can be satisfactorily decomposed by adding them in aqueous suspension to the aqueous cupro-cupri sulphite-sodium nitrite mixture. Incidentally, steric hindrance appears to retard the formation of diazonium cobaltinitrites, for whereas tetrazotised 4 : 4'-dichloro-3 : 3'-diaminodiphenyl eventually affords an 85—90% yield of its tetrazonium cobaltinitrite, the formation is slow compared with that of tetrazotised benzidine.

It is of interest that the colours of 2-nitronaphthalene-1-diazonium sulphate and of 1-nitro-2-diazonium sulphate are yellow-orange and red-orange like those of the parent 2-nitro-1- and 1-nitro-2-naphthylamines.

Contardi and Mor (*Rend. Ist. Lomb. Sci. Lett.*, 1924, 57, 646; *Annali Chim. Appl.*, *loc. cit.*), from a study of the replacement of the diazonium by the nitro-group for more than 40 different amines, conclude that the introduction of the nitro-group is facilitated when nitro-groups or halogens are present in the nucleus of the amine, and this is in accord with the viewpoint of Hodgson, Leigh, and Turner (*J.*, 1942, 744) who postulated the ease of replacement of the diazonium group to depend on the positivity of the carbon atom to which the diazonium group is attached, *viz.*, the greater the positivity, the readier the replacement by halogens or the nitro-group, and the less the positivity, the greater the proneness to attack by anionoid water with replacement of the diazonium by the hydroxyl group and formation of phenols or naphthols. The reactivity of cupri-salts for replacement of diazonium by nitro-groups as found by Contardi *et al.*, and also by Hodgson and Marsden (*loc. cit.*) for the decomposition of aryldiazonium cobaltinitrites, is evidence which supports the interpretation of the Sandmeyer reaction given by Hodgson, Birtwell, and Walker (*J.*, 1941, 770; 1942, 720).

EXPERIMENTAL.

General Decomposition Procedure as indicated by the Preparation of 1 : 4-Dinitronaphthalene.—Powdered sodium nitrite (10 g.) was stirred into sulphuric acid (50 c.c., *d* 1.84), and the mixture treated gradually below 20° (external cooling) with a solution of 4-nitro-1-naphthylamine (10 g.) in glacial acetic acid (100 c.c.), and subsequently stirred for 20 minutes. Ether (700 c.c.) was next stirred into the solution at 0°, the mixture kept for 1 hour, the crystalline precipitate (by scratching) of 4-nitronaphthalene-1-diazonium sulphate filtered off, washed free from acid with ether, and dissolved in water (100 c.c.), and the solution stirred slowly into the mixture of cupro-cupri sulphite prepared as follows. An aqueous solution of crystallised sodium sulphite (50 g.) was stirred into one of crystallised copper sulphate (50 g.), and the greenish yellow-brown precipitate filtered off, washed with water, ground into a slurry with water, and then stirred into a mixture of sodium nitrite (100 g.) in water (400

c.c.). Decomposition was very rapid (cf. Hantzsch and Blagden, *loc. cit.*), and foam was broken periodically by addition of small amounts of ether; after 1 hour's stirring, when most of the inorganic matter has passed into the dark green solution, the precipitate of crude 1 : 4-dinitronaphthalene was filtered off, washed in the sequence, water, dilute sodium hydroxide, and water, dried, and crystallised from aqueous methyl alcohol from which it separated in pale yellow needles, m. p. 133.5° (Hodgson and Hathway, *J.*, 1945, 453, give m. p. 134°) (Found : N, 13.0. Calc. for $C_{10}H_6O_2N_2$: N, 12.8%); or, it can be purified by steam distillation, which for this compound is a rather slow process. Yield of pure 1 : 4-dinitronaphthalene, 7.5 g. (ca. 65%). Usually, where a readily volatile nitro-compound is formed, the steam method of removal is the more convenient.

Estimation of Yield of Diazonium Sulphate.—The solution of the diazonium sulphate in water was made up to a definite volume, an aliquot portion stirred into the alkaline β -naphthol, the precipitated arylazo- β -naphthol removed, washed, dried, and weighed, and the corresponding amount of aryl- or naphthyl-diazonium sulphate calculated.

Preparation of 3 : 3' : 4 : 4'-Tetranitrodiphenyl.—3 : 3'-Dinitrobenzidine (5 g.) was dissolved in sulphuric acid (25 c.c., *d* 1.84), powdered sodium nitrite (5 g.) added gradually below 40°, and the mixture stirred below 20° into glacial acetic acid (50 c.c.); after 30 minutes, ether (200 c.c.) was added at 0°, the mixture kept for 1 hour, and the precipitated solid tetrazonium sulphate filtered off and dealt with as by the general method. The crude 3 : 3' : 4 : 4'-tetranitrodiphenyl was filtered off, washed with water, dilute sodium hydroxide, and finally with water, dried, extracted with boiling toluene (250 c.c.), and the extract concentrated to 25 c.c.; 3 : 3' : 4 : 4'-tetranitrodiphenyl crystallised out, m. p. 188–190°, and separated subsequently from boiling 80% acetic acid in clusters of yellow needles, m. p. 191–193° (Ullmann and Bielecki, *Ber.*, 1901, **34**, 2129, give m. p. 186°) (Found : N, 16.9. Calc. for $C_{12}H_6O_8N_4$: N, 16.8%).

Preparation of 3 : 4 : 5-Trinitrotoluene.—Solid sodium nitrite (5 g.) was stirred into sulphuric acid (25 c.c., *d* 1.84), and 3 : 5-dinitro-*p*-toluidine (5 g.) was stirred below 40° into this mixture, which was then added gradually below 20° to glacial acetic acid (50 c.c.). After 30 minutes, ether (200 c.c.) was added at 0°, and the precipitated diazonium sulphate dealt with as above. After decomposition, the crude 3 : 4 : 5-trinitrotoluene was extracted thrice with boiling toluene (150 c.c. in all), and the extract concentrated to 15 c.c.; magnificent monoclinic needles of an almost pure product separated (1.3 g., m. p. 135°) (Körner and Contardi, *Atti R. Accad. Lincei*, 1915, [5], **24**, 892, give m. p. 137.5°) (Found : N, 18.7. Calc. for $C_7H_5O_6N_3$: N, 18.5%).

261. The Reaction between Acetone and Ammonia : The Formation of Pyrimidine Compounds Analogous to the Aldoxans of Späth.

By R. B. BRADBURY, N. C. HANCOX, and H. H. HATT.

The reaction of acetone with ammonia can be conducted to give 90% yields of the monohydrate of 2 : 2 : 4 : 4 : 6-pentamethyl-2 : 3 : 4 : 5-tetrahydropyrimidine, which is readily dehydrated to the anhydrous base. By reduction with sodium in alcohol it gives the corresponding hexahydropyrimidine, and with aluminium amalgam an open chain primary-secondary diamine, $C_6H_{12}N_2$. The hexahydropyrimidine is hydrolysed with extreme ease to 2 : 4-diamino-2-methylpentane and acetone.

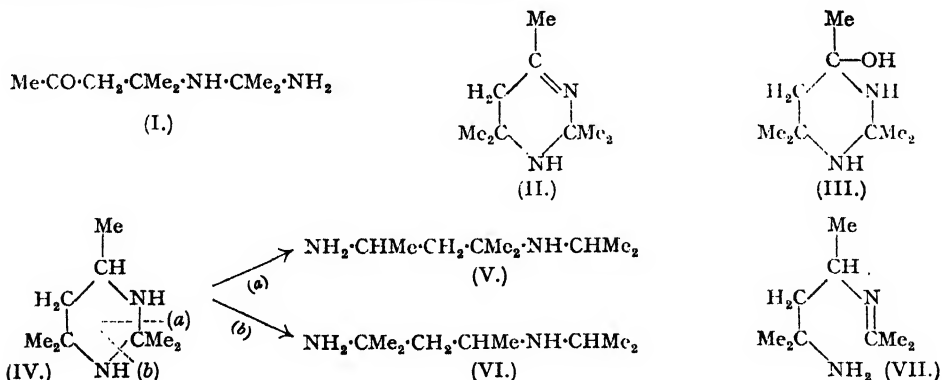

The mechanism of the formation of (II) is discussed in the light of its synthesis from mesityl oxide, acetone, and ammonia, and its quantitative hydrolysis to diacetoneamine.

Mesityl oxide and ammonia can be condensed to produce a substituted tetrahydropyrimidine analogous in structure to paralldol.

DIACETONAMINE and triacetonamine can both be obtained from the reaction of acetone with ammonia followed by acidification of the reaction products, and Heintz (*Annalen*, 1874, **174**, 133) first showed that triacetonamine was produced if the reaction mixture was heated, but that at room temperature diacetonamine was the chief product. The preparation of these compounds has since been improved by the use of calcium chloride to hasten the absorption of ammonia and to assist in the removal of water (Everest, *J.*, 1919, **115**, 588; Francis, *J.*, 1927, 2897). Further Suzuki and Horie (*Bull. Inst. Phys. Chem. Res. Japan*, 1932, **11**, 383) have found that the formation of diacetonamine was catalysed by ammonium salts, especially the nitrate and nitrite. Other compounds have been obtained from this reaction. Hock and Stuhlmann (*Ber.*, 1928, **61**, 470) by working at low temperatures isolated a compound C_9H_9ON which, as it decomposed at room temperatures into acetone and ammonia, they regarded as the initial product of the reaction analogous to aldehyde-ammonia. Patterson and McMillan (*J.*, 1921, **119**, 267) found that after a protracted reaction period a compound $C_9H_{20}ON_2$ could be obtained by cooling, to which they assigned structure (I). It has not hitherto been further investigated.

We have now found that, by the use of ammonium chloride and calcium chloride as catalysts, this compound is formed in 90% yield from acetone in 24 hours. From examination of its properties we conclude that it is a hydrate of 2 : 2 : 4 : 4 : 6-pentamethyl-2 : 3 : 4 : 5-tetrahydropyrimidine (II) to which it can be readily dehydrated over sodium hydroxide or sulphuric acid, or by distillation alone or with benzene as entrainer. The anhydrous base readily absorbs water to re-form the hydrate, and the facility of these changes is evidence for the hydrate structure assigned rather than the possible alternative (III). It seems possible that (II) may be identical with the compound $C_9H_{18}N_2$ named "acetonin" by Städeler (*Annalen*, 1859, **111**, 305; Mulder, *ibid.*, 1873, **168**, 229).

The base (II) is readily hydrolysed by boiling water to mesityl oxide, acetone, and ammonia, and by oxalic acid to ammonium and diacetonamine hydrogen oxalates and acetone. The observed molecular refraction (47·8) of the anhydrous base agrees well with the value calculated for structure (II) (47·84). Further support to this structure is given by the observation that both (II) and its hydrate are reduced by sodium and alcohol to 2 : 2 : 4 : 4 : 6-pentamethylhexahydropyrimidine (IV) and that a diamine of structure (V) or (VI) is produced by the action of aluminium amalgam on (II), its hydrate, or (IV).

The pentamethylhexahydropyrimidine (IV) is hydrolysed more readily than the parent hexahydropyrimidine, first described by Titherley and Branch (*J.*, 1913, **103**, 330), yielding 2 : 4-diamino-2-methylpentane and acetone rapidly with dilute acids and slowly with water alone. Although it is readily converted into open chain compounds, there is no evidence for the co-existence of the Schiff's base (VII), for, unlike hexahydropyrimidine, (IV) distils without the formation of a resinous polymer and the observed molecular refraction (48·7) agrees closely with that calculated for (IV) (48·77).

Ease of ring fission in the methyl-substituted hydropyrimidines doubtless accounts in part for failure to prepare acyl derivatives, which the presence of imino- and hydroxyl groups in (II), (III), and (IV) suggests as possible. Titherley and Branch (*loc. cit.*) obtained the dibenzoyl derivative of hexahydropyrimidine by normal Schotten-Baumann procedure, but from (II) and its hydrate we obtained only *N*-benzoyldiacetonamine and from (IV) only 2 : 4-dibenzamido-2-

methylpentane. 4 : 4 : 6-Trimethylhexahydropyrimidine has been synthesised and shows intermediate properties, giving a little of its *dibenzoyl* derivative together with much 2 : 4-dibenzamido-2-methylpentane. Failure to acylate can be viewed as evidence for the hydrate structure rather than (III), for the imino-group in (II) is sterically almost identically placed with the imino-group of triacetoneamine, which forms a hydrate and a nitroso-derivative, but so far has not been benzoylated. Actually (II) reacts with nitrous acid and gives a compound of the expected composition, $C_6H_{17}ON_3$, but the yield is small and the properties are abnormal.

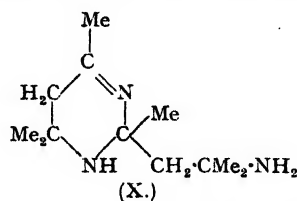

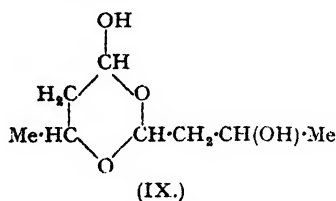

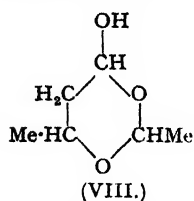

The hydrate of (II) can be synthesised from mesityl oxide, acetone, and ammonia, thus reversing the hydrolysis with acids and suggesting that formation from acetone proceeds by way of diacetoneamine and not through the hypothetical intermediate, $CMe_2(NH_2) \cdot CMe_2 \cdot OH$, proposed by Patterson and McMillan. The preparation of diacetoneamine from acetone and ammonia by the method of Everest therefore involves the formation of the hydrate, followed by its hydrolysis with oxalic acid, the scheme being :

Presumably (II) is also an intermediate in the formation of triacetoneamine.

The strong catalytic action of ammonium salts in the formation of (II) can be attributed to their acidic character in a mixture of acetone and ammonia. In support of this view, trimethylammonium chloride, which can still donate a proton, exhibits a like powerful catalytic action, whereas tetramethylammonium chloride, being unable to react in this way, has an action even weaker than calcium chloride. These catalytic effects must apply mainly to the initial formation of diacetoneamine, for the hydrate of (II) is formed readily from diacetoneamine, acetone, and ammonia in absence of a catalyst.

An analogy is apparent between the suggested mechanism for the reaction between acetone and ammonia and that given by Späth for the formation of aldoxan (VIII) by condensation of acetaldehyde (*Ber.*, 1943, 76, 57). The reaction between mesityl oxide and ammonia provides a further analogy. When the ammonia used is in excess of that needed to form diacetoneamine, a compound of the formula $C_{12}H_{25}N_3$ forms slowly. To this is assigned structure (X), closely analogous to the structure (IX) determined by Späth for paralldol. Like the substituted

tetrahydropyrimidine (II), this 2 : 4 : 4 : 6-tetramethyl-2-(2-aminoisobutyl)-2 : 3 : 4 : 5-tetrahydropyrimidine is readily reduced to the corresponding substituted hexahydropyrimidine. It forms no hydrate, but, like (II), is unstable in the presence of acids, which cause reversal of the above synthesis and give ammonium and diacetoneamine hydrogen oxalates as the chief products of decomposition.

Diaceetonamine is conveniently prepared from the hydrate of (II), a yield of 93% being obtained by boiling with alcoholic oxalic acid. This represents a yield of 56% based on the acetone used to make the hydrate and compares favourably with the 37–42% reported by Everest (*loc. cit.*), in which allowance was made for recovered acetone, and with the 70–75% yields from mesityl oxide (*Org. Synth.*, VI, 28; Smith and Adkins, *J. Amer. Chem. Soc.*, 1938, 60, 407). The synthesis of 2 : 4-diamino-2-methylpentane from acetone through the hydrate of (II) and (IV) comprises three steps all with yields exceeding 80%, and is preferable to the preparation from acetone proceeding through mesityl oxide, diacetoneamine, and its oxime.

EXPERIMENTAL.

(All melting points are corrected.)

2 : 2 : 4 : 4 : 6-Pentamethyl-2 : 3 : 4 : 5-tetrahydropyrimidine Hydrate.—(a) Acetone (290 g., 5 mol.), calcium chloride ("A.R. dried", 40 g.), and ammonium chloride (10 g.) were cooled in an autoclave to -40° , and liquid ammonia (110 g., 6.5 mol.) was added. After 24 hours' stirring at room temperature, the solid product was melted by gentle warming (40°), and the top layer separated, allowed to solidify,

and dried on porous plates (yield, 252 g.; 88%). This material is almost pure, but the small amounts of ammonium and calcium chlorides present can be removed by crystallisation from ether.

The amounts of ammonia, ammonium chloride, and calcium chloride stated above are the least for a good yield, and the use of larger amounts does not perceptibly affect the yield. When the reaction time is prolonged to 3 days the yield is increased by 1–2%.

With acetone and ammonia alone the reaction mixture remains liquid for months, although some hydrate is formed and crystallises out on cooling to -40° . Thus after 7 days a 17% yield is obtained. In presence of ammonium chloride the hydrate forms rapidly, but the solid reaction product does not separate into two layers when melted, and removal of ammonium chloride requires extraction with ether. With calcium chloride alone the yield is smaller even with a longer reaction period. The product, however, forms two liquids; the lower, containing the calcium chloride and water, is easily removed, and the upper when cooled to -40° , deposits the hydrate. The presence of small amounts of lime in the calcium chloride does not affect the yield. The presence of water is beneficial; thus fused calcium chloride alone and with half its weight of water gave yields of 55 and 65% respectively.

The table summarises the results of experiments in which 290 g. (5 mols.) of acetone and 110 g. (6.5 mols.) of ammonia were used. The reaction took place at room temperatures and the amount of catalyst used was always equivalent to 10 g. of ammonium chloride.

* Added as a 55% aqueous solution.

(b) Mesityl oxide (120 g., 1.2 mol.) and ammonia (26 g., 1.5 mol.) were placed in an autoclave cooled to -40° and stirred for 3 days at room temperature. The mixture was again cooled, acetone (71 g., 1.2 mol.) and ammonia (40 g., 2.4 mol.) were added and the stirring was continued for 4 days. The solid hydrate of (II) was purified by crystallisation from ether (yield, 139 g.; 66%).

The hydrate when freshly crystallised from ether forms colourless crystals, m. p. $43-44^{\circ}$ [Found: C, 62.4; H, 11.5; N, 16.3; H₂O (by Dean-Stark), 10.5; equiv. (titration), 87. C₉H₁₂N₂·H₂O requires C, 62.7; H, 11.7; N, 16.3; H₂O, 10.5%; equiv., 86]. In air it slowly becomes yellow and decomposes, liberating ammonia, but it can be kept for a considerable time in a stoppered vessel in a refrigerator. It is extremely volatile and sublimes to give large, well-formed crystals of hexagonal habit. It is soluble in cold water (70 g. per 100 ml.), in cold ether (19 g. per 100 ml.), and in most organic solvents.

The oxalate was prepared from equimolecular quantities of the hydrate (II) and anhydrous oxalic acid in ether (Found: C, 44.5; H, 7.1; N, 8.0. C₉H₂₀ON₂·2H₂C₂O₄ requires C, 44.3; H, 6.8; N, 8.0%).

When to the hydrate (II) and an equivalent amount of aqueous sodium nitrite at 0° , two equivalents of 2N-hydrochloric acid were added, reaction occurred with deposition of a colourless crystalline substance during 3 hours (yield, 10–15%), m. p. $168-170^{\circ}$ (decomp.) (from acetone). The low yield, high m. p., and decomposition with dilute mineral acid without liberation of nitrous acid conflict with the supposition that it is the nitroso-derivative of (II), although the analytical data are in agreement. Molecular weight determinations gave double the expected values [Found: C, 59.2; H, 8.8; N, 22.8; M (in nitrobenzene), 371. C₉H₁₇ON₂ requires C, 59.0; H, 9.3; N, 23.0%; M, 183].

Diacetonamine Hydrogen Oxalate.—The crude hydrate of (II) (269 g.) prepared from acetone (290 g.) was dissolved in alcohol (300 ml.). An aliquot (5 ml.) was titrated with oxalic acid to determine the amount required (twice that needed for neutralisation: 365 g.). In the titration it is necessary to add about 3/4ths of the estimated amount of acid and then to warm to 80° for a few minutes to complete the hydrolysis of the hydrate. Titration at room temperature as directed by Everest gives low results and leads to the use of insufficient oxalic acid. The oxalic acid was dissolved in alcohol (2000 ml.), stirred vigorously, and the solution of the hydrate added in $\frac{1}{2}$ hour at 30° or less. After a further $\frac{1}{2}$ hour, 100 ml. of the solvent were removed and the ammonium hydrogen oxalate was filtered from the hot solution and extracted thrice with 300 ml. portions of boiling alcohol. The combined filtrates were cooled rapidly, and after 3 hours the diacetonamine hydrogen oxalate was collected and dried (m. p. $123-125^{\circ}$). The mother liquors, on evaporation, yielded a further 20 g. Yield, 309 g.; 56% based on the acetone taken. The maximum yield on this basis is 66.7%.

2 : 2 : 4 : 4 : 6-Pentamethyl-2 : 3 : 4 : 5-tetrahydropyrimidine (II).—Distillation of the hydrate under reduced pressure or dehydration using benzene as an entrainer, gives a liquid from which the base (II) is obtained by fractionation under reduced pressure (yield, 80%), b. p., 171° (decomp.)/774 mm., $55^{\circ}/10$ mm., $85^{\circ}/50$ mm.; d_{40}^{20} 0.8769; n_D^{20} 1.4561; $[R_L]_D$ 47.8 (Calc., 47.84) (Found: C, 70.3; H, 11.3; N, 18.5; equiv., 77. C₉H₁₈N₂ requires C, 70.1; H, 11.7; N, 18.2%; equiv., 77). The liquid is pale yellow and of ammoniacal odour. Addition of water to (II) gave the hydrate in 72% yield. There is some decomposition during the formation of (II), the water removed is strongly ammoniacal, and materials boiling higher than (II) are formed.

Both bases are readily decomposed in aqueous solution. The hydrate (1.72 g.) when boiled with an aqueous solution of oxalic acid (2.52 g.), the water removed on a steam-bath under slightly reduced pressure, and the dry residue extracted with absolute alcohol left ammonium hydrogen oxalate (1.03 g.; theory, 1.07 g.). The alcoholic solution on evaporation gave crude diacetonamine hydrogen oxalate, m. p., 124° , after crystallisation. In another experiment 1.72 g. were boiled with excess of aqueous oxalic acid and the acetone distilling was absorbed in water and estimated by the method of Messenger (Found: 0.57 g. Calc.: 0.58 g.). Attempts were made to benzoylate the hydrate by normal

Schotten-Baumann procedure, in dry pyridine, and in ether in presence of potassium carbonate. The only products identified were benzamide and *N*-benzoyldiacetonamine [m. p. (from alcohol) and mixed m. p. 99–100°].

2 : 2 : 4 : 4 : 6-Pentamethylhexahydropyrimidine (IV).—The hydrate (86 g.) was reduced with sodium (40 g.) in alcohol (250 ml.) and the product was first distilled with the alcohol and then separated by fractional distillation. The pure product (64 g., 82%) was colourless fuming liquid of sweet, slightly ammoniacal odour. It absorbs carbon dioxide from air and is hygroscopic; b. p., 56.5°/10 mm., 90.5°/50 mm., 172–175° (decomp.)/765 mm.; d_{25}^{25} 0.8653, n_D^{25} 1.4517; $[R_L]_D$ 48.7 [Calc. for (IV), 48.77; for (VII), 49.86] (Found: C, 69.3; H, 12.8; N, 18.2; equiv., 77. $C_8H_{20}N_2$ requires C, 69.3; H, 12.8; N, 18.0%; equiv., 78). Reduction of (II) also yields (IV), but preparation from the hydrate is preferable. Hydrolysis of (IV) with hot water is rapid and in an hour 80% of the calculated amount of acetone was liberated.

Conversion of (IV) into 2 : 4-Diamino-2-methylpentane (XI).—(IV) (54 g.) was added slowly to 2*N*-hydrochloric acid (380 ml.) at 0°, and after a day at room temperature the mixture was heated to remove acetone. Sufficient solid sodium hydroxide was added to give a 40% aqueous solution, the diamine layer was separated, and the aqueous liquors were extracted with ether. The diamine was dried over potassium hydroxide and barium oxide. Fractional distillation gave a colourless liquid (yield, 33.5 g.; 83%), b. p. 45–46°/10 mm.; d_{25}^{25} 0.8312; n_D^{25} 1.4386; $[R_L]_D$ 36.8 (Calc., 36.75) (Found: C, 62.6; H, 13.5; N, 23.1. $C_6H_{14}N_2$ requires C, 62.1; H, 13.8; N, 24.1%). (XI) was also prepared from diacetanamine by the method of Harries and Adamiantz (*Ber.*, 1901, 34, 301); b. p. 42–46/10 mm.; n_D^{25} 1.439; d_{25}^{25} 0.836.

The diacetyl derivative obtained from (XI) and either acetic anhydride or keten formed colourless crystals from chloroform, m. p., 163° (Found: C, 60.0; H, 10.0; N, 14.2. $C_{10}H_{20}O_4N_2$ requires C, 60.0; H, 10.0; N, 14.0%). The dibenzoyl derivative obtained by the Schotten-Baumann procedure from (XI) formed colourless rosettes from alcohol, m. p., 153° (Found: C, 74.2; H, 7.4; N, 8.7. $C_{20}H_{24}O_4N_2$ requires C, 74.1; H, 7.4; N, 8.6%); it showed no depression of melting point with the derivative prepared from the specimen of (XI) synthesised from diacetanamine. This same dibenzoyl derivative is slowly formed when (IV) is benzoylated.

2 : 4-Diamino-2-methylpentane (XI), chloro-2 : 4-dinitrobenzene, sodium acetate, and alcohol were refluxed for 1 hour. The *bis*-2 : 4-dinitrophenyl derivative formed yellow crystals from *o*-dichlorobenzene, m. p., 235° (Found: C, 48.3; H, 4.4; N, 18.9. $C_{18}H_{20}O_4N_4$ requires C, 48.2; H, 4.5; N, 18.7%). With like experimental conditions (IV) gave this same compound.

2-Keto-4 : 4 : 6-trimethylhexahydropyrimidine.—Equimolecular amounts of 2 : 4-diamino-2-methylpentane and urea were heated at 150° for 1 hour. The product separated from acetone as white crystals, m. p. 205–206° (Found: C, 59.5; H, 9.7; N, 19.9. $C_7H_{14}ON_2$ requires C, 59.2; H, 9.9; N, 19.7%).

4 : 4 : 6-Trimethylhexahydropyrimidine (XII).—The method used by Titherley and Branch (*J.*, 1913, 103, 334) for hexahydropyrimidine was adopted, and 2 : 4-diamino-2-methylpentane (XI) (2.09 g.) was neutralised with 0.2*N*-hydrochloric acid, an equal weight of (XI) added, followed by 36% aqueous formaldehyde (3.5 ml.) in 3 hours. After a further 2 hours, potassium hydroxide (60 g.) was added, the product extracted with ether, and the solution dried (BaO) and distilled. Yield, 3.3 g.; b. p. 55–57°/10 mm.; n_D^{25} 1.457 (Found: C, 65.7; H, 12.8; N, 21.7; equiv., 132. $C_7H_{14}N_2$ requires C, 65.7; H, 12.5; N, 21.9%; equiv. (monoacid), 128).

Trimethylhexahydropyrimidine (XII), by Schotten-Baumann procedure, gave its own *NN'*-dibenzoyl derivative, together with 2 : 4-dibenzamido-2-methylpentane. The former being the more soluble, only a partial separation was made by fractional crystallisation from alcohol, and the final separation was made by hand picking. This dibenzoyl derivative forms needles, m. p. 156° (Found: C, 75.0; H, 6.9; N, 8.3. $C_{21}H_{24}O_4N_2$ requires C, 74.8; H, 7.1; N, 8.3%).

2 (or 4)-Amino-4 (or 2)-isopropylamino-2-methylpentane (V) or (VI).—This was obtained by reduction of (II), its hydrate, or (IV) with an equal weight of aluminium amalgam in moist ether. The reaction proceeded slowly and was complete after 2 days; the ethereal liquors were then filtered off, and the oxide sludge was washed with ether. When distilling the ethereal liquors the alcohol introduced with the amalgam distilled as a fore-fraction containing much diamine. Yields of pure diamine were 60–70% when this fore-fraction was neglected; with recovery from it the yields rose to 85%. Dried over sodium, (VI) forms a colourless hygroscopic liquid, b. p. 178°/760 mm. (no decomp.), 65–67°/10 mm., 104°/65 mm.; d_{25}^{25} 0.8130; n_D^{25} 1.432 (Found: C, 68.4; H, 14.0; N, 17.7; equiv., 81. $C_9H_{22}N_2$ requires C, 68.4; H, 13.9; N, 17.7%; equiv., 79).

The dihydrochloride, prepared in dry ether and crystallised from amyl alcohol, had m. p. 250° (decomp.) (Found: Cl, 30.5. $C_9H_{22}N_2 \cdot 2HCl$ requires 30.7%). The dibenzoyl derivative was prepared by the Schotten-Baumann method; crystals from alcohol, m. p. 133° (Found: C, 75.2; H, 8.25; N, 7.8. $C_{23}H_{26}O_4N_2$ requires C, 75.4; H, 8.2; N, 7.6%).

Sufficient chloro-2 : 4-dinitrobenzene was used with sodium acetate in alcohol to substitute both amino-groups, but only one reacted. The 2 : 4-dinitrophenyl derivative crystallised from alcohol in orange needles, m. p. 91° (Found: C, 55.6; H, 7.4; N, 17.7. $C_{18}H_{20}O_4N_4$ requires C, 55.6; H, 7.4; N, 17.3%).

2 : 4 : 4 : 6-Tetramethyl-2-(2-aminoisobutyl)-2 : 3 : 4 : 5-tetrahydropyrimidine (X).—Mesityl oxide (120 g.) and liquid ammonia (49 g.) were cooled in an autoclave to –40° and then stirred for 24 hours at room temperature. The autoclave was then cooled again and a further quantity of mesityl oxide (120 g.) and ammonia (26 g.) added. After 6 days at room temperature, the product was removed and cooled to –40°. The white crystalline solid that separated (58 g.) crystallised from ether in white flakes, m. p. 61–62° (Found: C, 68.0; H, 11.5; N, 19.9; equiv., 71; *M* (in nitrobenzene), 218. $C_{15}H_{22}N_2$ requires C, 68.2; H, 11.8; N, 19.9%; equiv., 70.3; *M*, 211).

This compound (X) reacts rapidly with a cold solution of oxalic acid in alcohol, a precipitate of ammonium hydrogen oxalate appearing shortly after the reagents are mixed. From (X) (2.11 g.) and oxalic acid hydrate (3.78 g.) in alcohol (10 ml.) after $\frac{1}{2}$ hour at the b. p., filtration gave ammonium hydrogen oxalate (1.8 g.) and concentration of the filtrate diacetanamine hydrogen oxalate (0.87 g.).

The latter melted at 124–125° after crystallisation (Found: C, 43.0; H, 7.8. Calc. for $C_8H_{17}O_6N$: C, 43.0; H, 7.6%). There were 2.1 g. of uncrystallisable residues.

2:4:4:6-Tetramethyl-2-(2-aminoisobutyl)hexahydropyrimidine.—Reduction of (X) (21 g.) in alcohol (100 ml.) with sodium (10 g.) followed by the addition of water (50 ml.) gave the product as an oil, which was dried and fractionally distilled (yield, 12–14 g.). It was a colourless liquid, b. p. 122–125°/10 mm.; d_{20}^{25} 0.8668; n_D^{25} 1.458 (Found: C, 67.4; H, 13.0; N, 20.1; equiv., 72. $C_{13}H_{27}N_3$ requires C, 67.6; H, 12.7; N, 19.7%; equiv., 71).

We wish to thank Mr. D. J. Clark, M.Sc., of these laboratories, for the micro-analyses.

262. The Structure of Glycogen. Ratio of Non-terminal to Terminal Glucose Residues.

By T. G. HALSALL, E. L. HIRST, and J. K. N. JONES.

An assay of the proportion of terminal groups present in various glycogens has been made by measuring the amount of formic acid liberated on oxidation of the polysaccharide by potassium periodate. All the glycogens examined gave results indicating that approximately 12 glucose residues were present per end group, except that certain samples of rabbit-liver glycogen contained approximately 18 residues per end group. The results are in agreement with determinations of the percentage of end groups arrived at by estimation of the tetramethyl glucose produced on hydrolysis of the methylated glycogen.

THE proportion of terminal groups present in samples of glycogen isolated from various sources has been determined previously by methylation of the polysaccharide followed by the quantitative determination of the amount of tetramethyl methyl-*d*-glucoside in the products of methanolysis of the methylated polysaccharide, and in this way it was found that for most samples the ratio of terminal to non-terminal glucose residues was approximately 1 to 12. Nevertheless, in certain samples of rabbit-liver glycogen the ratio was nearer 1 to 18. No completely satisfactory explanation of this variation has yet been put forward, and further investigation was clearly needed. The examination of a large number of samples by the classical methylation technique is a lengthy operation, but starches and glycogens respond readily to the periodic acid oxidation process in which, under carefully standardised conditions, formic acid is liberated quantitatively from the terminal residues of each side chain, and it was decided, therefore, to examine various samples of glycogen by this method (cf. Brown, Dunstan, Halsall, Hirst, and Jones, *Nature*, 1945, 156, 785; *idem*, *J.*, in the press). In some instances comparative experiments were made by the methylation method, using newly developed semi-micro-methods for the determination of the tetramethyl methylglucoside which arises from each end group (Bell, *J.*, 1944, 473; Jones, *J.*, 1944, 333; Brown and Jones, in the press).

Through the kindness of Dr. D. J. Bell of Cambridge University, we were able to investigate numerous samples of glycogens which he had isolated from various sources. These included glycogen from *Ascaris lumbricoides*, *Mytilus edulis*, human muscle, rabbit liver, rabbit muscle (fasted), and horse muscle. Some of these had already been assayed by him using the methylation procedure. A check was thus provided of the results derived by determination of the formic acid produced after oxidation of the glycogen with potassium periodate. Figures in excellent agreement with those obtained by the use of the methylation procedure were observed. Dr. F. Smith very kindly placed at our disposal samples of guinea-pig-liver glycogen and rabbit-liver glycogen which had been assayed by the methylation technique at Birmingham University.

The proportion of end groups in rabbit-liver glycogen was first determined by Haworth and Percival (*J.*, 1932, 2277) who reported the figure of 1 for every 12 glucose residues. Examination of another sample of rabbit-liver glycogen by Haworth, Hirst, and Isherwood (*J.*, 1937, 577) showed, however, that this glycogen contained approximately 18 glucose residues per end group. This result was confirmed by Bell (*Biochem. J.*, 1936, 30, 1612) and by Bacon, Baldwin, and Bell (*ibid.*, 1944, 38, 198) who demonstrated that the ratio of terminal to non-terminal residues in rabbit-liver glycogen may be either 12 to 1 or 18 to 1 approximately, the value observed being apparently dependent upon the carbohydrate diet of the rabbit. We have now confirmed by the periodate oxidation method the higher figure for the sample of rabbit-liver glycogen examined by Haworth, Hirst, and Isherwood, and have obtained also a ratio of 18 to 1 approximately, by both methods of assay, for another sample of rabbit-liver glycogen prepared

by Messrs. Hopkin & Williams Ltd. On the other hand, the sample of rabbit-liver glycogen which had been found by Bell to give the value 12 gave a low value by the periodate method also. Further investigation is clearly required to ascertain the precise reasons for these unpredictable variations which appear to occur only in rabbit-liver glycogen. In all other cases, including those cited in the table and the numerous samples of fish-liver and fish-muscle glycogen examined by Smith (*J.*, 1939, 1915), the value obtained has been 12 approximately.

EXPERIMENTAL

Potassium Periodate Oxidation of Glycogens. General Procedure.—The glycogen (*ca.* 500 mg.) was placed in a 500 ml. stoppered bottle which had been cleaned with chromic acid and steamed out. A known volume of water was added, followed by potassium chloride (5 g.) and a known excess of an aqueous solution of sodium metaperiodate. The oxidations were carried out at 15° with continuous shaking and in dim light (sunlight must be avoided). Portions of the solution (20 ml.) were withdrawn at intervals, excess of ethylene glycol was added, and the formic acid present was estimated by titration with 0.1*N*-barium hydroxide using a micro-burette and methyl-red as indicator. The resulting titres, after correction when necessary to allow for the slight acidity or alkalinity of the glycogen, were plotted against time to make sure that the normal type of reaction was proceeding, and the acid titre corresponding to 150 hours was used in the calculations, this being the time required for the liberation of 1 mol. of formic acid from β -methyl-*D*-maltoide under these conditions (Halsall, Hirst, and Jones, *J.*, *loc. cit.*). From this titre the size of the repeating unit was calculated. The results are given in the table.

Source of glycogen.	Wt. of glycogen (mg.).	Yield of formic acid (mg.).	Glucose residues per end group.	
			(a) By periodate method.	(b) By methylation method.
1. <i>Ascaris lumbricoides</i>	567	13.5	12	13—14 (a)
2. <i>Mytilus edulis</i>	510	14.1	10	11 (b)
3. Human muscle	518.8	12.9	11	—
4. Rabbit (fasted) muscle	510.5	11.0	13	—
5. Horse muscle	400.4	8.1	14	12 (c)
6. Rabbit liver	365.5	7.2	14	12 (d)
7. Rabbit liver	509	9.0	16	18 (e)
8. Rabbit liver	871	13.8	18	18 (f)
9. Rabbit liver	216	4.2	14	12 (g)
10. Guinea-pig liver	174.5	3.9	13	12 (g)

Glycogens 1—6 were prepared by Dr. D. J. Bell.

Glycogen 7 was a sample of the material used by Haworth, Hirst, and Isherwood (*loc. cit.*).

Glycogen 8 was prepared by Messrs. Hopkin & Williams, Ltd.

Glycogens 9 and 10 were prepared by Dr. F. Smith.

(a) Bell, *J.*, 1944, 474.

(b) This figure was obtained for another sample examined by Meyer, *Naturwiss.*, 1941, 29, 287.

(c) Bell, *Biochem. J.*, 1935, 29, 2031.

(d) Bell, *Biochem. J.*, 1937, 31, 1683.

(e) Haworth, Hirst, and Isherwood (*loc. cit.*).

(f) Present paper.

(g) F. Smith (private communication).

Size of Repeating Unit of Rabbit-liver Glycogen (No. 8 in Table), by the Methylation Method.—The glycogen was methylated with methyl sulphate and sodium hydroxide according to the method of Hirst and Young (*J.*, 1939, 1471). The methylated glycogen [759.5 mg.; $[\alpha]_D^{25} + 206^\circ$ in chloroform (*c.* 8.5); OMe, 45.1%] was hydrolysed with methyl-alcoholic hydrogen chloride (1.5%; 100 ml.) and the amount of 2:3:4:6-tetramethyl methylglucoside in the resulting mixture of glucosides was estimated by the partition method of Brown and Jones (this vol., p. 1344). Yield of 2:3:4:6-tetramethyl methylglucoside, 50.3 mg.; $n_D^{18} 1.4445$; $[\alpha]_D^{25} + 66^\circ$ in water (*c.* 2.3); corresponding to the presence of 18—19 glucose residues per end group.

We wish to thank Mr. L. Hough for assistance in the experimental work, and one of us (T. G. H.) wishes to thank the British Cotton Industry Research Association for the award of a Shirley Research Fellowship.

THE UNIVERSITY, MANCHESTER.

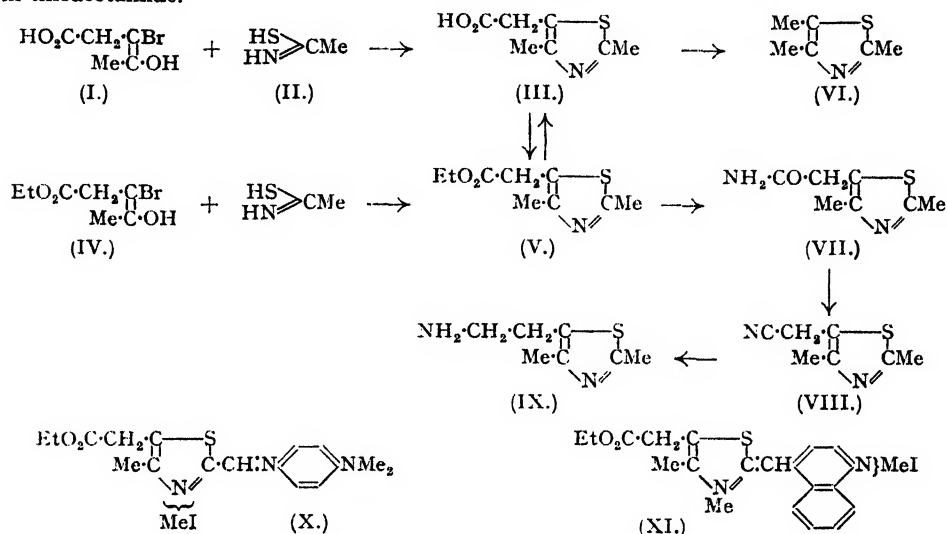

[Received, December 23rd, 1946.]

263. The Conversion of Sucrose into Thiazole Derivatives. Part II. 2:4-Dimethylthiazole Derivatives and 2:4:5-Trimethylthiazole.

By HILDA GREGORY and L. F. WIGGINS.

Condensation of β -bromolævulinic acid and its ethyl ester with thioacetamide yields 2:4-dimethylthiazole-5-acetic acid and ethyl 2:4-dimethylthiazole-5-acetate respectively. Several derivatives of the latter product are described, and decarboxylation of 2:4-dimethylthiazole-5-acetic acid affords a convenient method for the preparation of 2:4:5-trimethylthiazole.

SUCROSE can be readily transformed into lævulic acid, and in Part I (this vol., p. 590) we described several sulphanilamidothiazoles, which were obtained through the condensation of β -bromolævulic acid and its ethyl ester with thiourea. Continuing this theme, we have now investigated the condensation of β -bromolævulic acid (I) with thioacetamide (II), whereby 2:4-dimethylthiazole-5-acetic acid hydrobromide is obtained; this is readily converted into 2:4-dimethylthiazole-5-acetic acid (III). The latter, on esterification, gave ethyl 2:4-dimethylthiazole-5-acetate (V), identical with the product of the condensation of ethyl β -bromolævulate (IV) with thioacetamide.

Decarboxylation of 2:4-dimethylthiazole-5-acetic acid was effected smoothly to give an 80% yield of 2:4:5-trimethylthiazole (VI). Hitherto, this trimethylthiazole has only been prepared by the condensation of thioacetamide with methyl 1-chloroethyl ketone (Roubleff, *Annalen*, 1890, 259, 258).

Treatment of the thiazole ester with concentrated aqueous ammonia gave the corresponding amide (VII) which was readily dehydrated with phosphorus oxychloride to 2:4-dimethyl-5-cyanomethylthiazole (VIII). The latter, on catalytic hydrogenation over Raney nickel, was converted into 2:4-dimethyl-5-2'-aminoethylthiazole (IX) which, however, was unstable and could only be isolated as the *dipicrate*. In view of the previous work of Hinegardner and Johnson (*J. Amer. Chem. Soc.*, 1930, 52, 3724), this compound should exhibit some physiological activity as a sympathomimetic agent.

It has been shown previously by Mills and Smith (*J.*, 1922, 121 2724) that the activity of the substituent methyl group in the thiazole ring depends upon its position. Thus, whereas 4-phenyl-2-methylthiazole will condense readily with benzaldehyde and phthalic anhydride, and its quaternary ammonium salts couple with *p*-dimethylaminobenzaldehyde, its isomer, 2-phenyl-4-methylthiazole, undergoes none of these reactions. In this work we found that ethyl 2:4-dimethylthiazole-5-acetate methiodide underwent reaction with only 1 mole of *p*-nitrosodimethylaniline to form 4-methyl-5-carbethoxymethylthiazole-2-aldehyde *p*-dimethylaminoanil methiodide (X) which was a brownish-green crystalline compound with a bluish-green metallic reflex, giving rise to deep purple aqueous solutions. Similarly, ethyl 2:4-dimethylthiazole-5-acetate methiodide condensed with 1 mole of quinoline methiodide to give a deep red crystalline compound which, by analogy to 4-phenyl-3-methyl-2-thiazolonyl-4-quinolymethane methiodide of Mills and Smith (*loc. cit.*), must be 3:4-dimethyl-5-carbethoxymethyl-2-thiazolonyl-4-quinolymethane methiodide (XI).

EXPERIMENTAL.

Ethyl 2:4-Dimethylthiazole-5-acetate.—To ethyl β -bromolævulate (20.8 g.) dissolved in ethyl alcohol (20 c.c.), thioacetamide (7.0 g.) was slowly added in small portions; an exothermic reaction occurred with formation of a yellow solution. After 12 hours at room temperature, the alcohol was removed and the thick yellow syrup thus obtained dissolved in water, a few drops of hydrochloric acid (5*N*) were added, and the solution was extracted with ether to remove any unchanged starting materials. Ammonia (5*N*) was added to the aqueous solution at 0° until the solution was slightly alkaline (litmus);

1402 The Conversion of Sucrose into Thiazole Derivatives. Part II.

a yellow oil then separated. The crude product was extracted with ether, and the ethereal layer was washed with water and dried (MgSO_4), and the ether removed. The residual liquid was distilled in a vacuum; ethyl 2 : 4-dimethylthiazole-5-acetate was thus obtained as a pale yellow liquid, b. p. $142^\circ/15$ mm., $212^\circ/756$ mm., n_D^{20} 1.4942. Yield, 11.6 g. (82.5%) (Found : C, 53.9; H, 6.1; N, 7.2; OEt, 23.1. $\text{C}_9\text{H}_{13}\text{O}_2\text{NS}$ requires C, 54.2; H, 6.5; N, 7.0; OEt, 22.6%). The picrate was obtained as a yellow, crystalline solid, m. p. 168° (Found : C, 42.4; H, 3.4; N, 13.1. $\text{C}_{18}\text{H}_{16}\text{O}_6\text{N}_4\text{S}$ requires C, 42.1; H, 3.7; N, 13.1%).

Condensation of β -Bromolævulic Acid with Thioacetamide.—Thioacetamide (1.0 g.) was added in portions to β -bromolævulic acid (2.25 g.) at 80° . After a few minutes, an exothermic reaction occurred, and when the mixture had cooled to room temperature, a partly solid product was obtained. This was pressed on a porous pile, and colourless crystals isolated, which were recrystallised from acetone-ethyl alcohol-light petroleum (b. p. 40 – 60°). After two recrystallisations, pure 2 : 4-dimethylthiazole-5-acetic acid hydrobromide was obtained as colourless crystals, m. p. 183° . Yield, 1.78 g. (61.2%) (Found : C, 33.7; H, 4.3. $\text{C}_9\text{H}_{10}\text{O}_2\text{NBrS}$ requires C, 33.4; H, 4.0%).

The free base was obtained from the hydrobromide (1.5 g.) by dissolving it in water (6 c.c.) and heating under reflux for 15 minutes. The strongly acid solution was cooled, and a concentrated aqueous solution of potassium hydroxide added carefully, until, when the solution was still acid to litmus, crystals separated. These were filtered off and recrystallised from hot water; m. p. 185° . Yield, 0.93 g. (91.4%).

Esterification of 2 : 4-Dimethylthiazole-5-acetic Acid.—The acid (2.0 g.) was heated under reflux with 2% ethyl-alcoholic hydrogen chloride (50 c.c.) for 6 hours. The resulting solution was neutralised with barium carbonate, the barium salts were filtered off, and the alcoholic solution was evaporated to dryness under reduced pressure. The residue was extracted with ether, and the ethereal extract evaporated to a brown liquid which was subsequently distilled; b. p. $212^\circ/745$ mm., n_D^{20} 1.4943 (Found : OEt, 22.9. Calc. for $\text{C}_9\text{H}_{13}\text{O}_2\text{NS}$: OEt, 22.6%). Yield of ethyl 2 : 4-dimethylthiazole-5-acetate, 1.46 g. (62.7%).

2 : 4 : 5-Trimethylthiazole.—2 : 4-Dimethylthiazole-5-acetic acid (0.8 g.) was heated on an oil-bath in a distillation flask. At 190° (bath temp.) the crystals melted; at 235° (bath temp.) carbon dioxide was evolved and a colourless, pungent smelling liquid distilled, b. p. 164 – 166° (vapour temp.), n_D^{20} 1.5060. Yield of 2 : 4 : 5-trimethylthiazole, 0.49 g. (82.5%). On treatment with one mol. of picric acid, yellow needles of 2 : 4 : 5-trimethylthiazole picrate were obtained, m. p. 133 – 134° (Found : C, 40.4; H, 3.7. Calc. for $\text{C}_{12}\text{H}_{15}\text{O}_7\text{N}_3\text{S}$: C, 40.4; H, 3.4%). Roubleff (*loc. cit.*) gives m. p. 133° .

2 : 4-Dimethylthiazole-5-acetamide.—Ethyl 2 : 4-dimethylthiazole-5-acetate (1.0 g.) was suspended in concentrated ammonia solution (d 0.88; 5 c.c.), and the mixture shaken for 2 hours; a clear yellow solution was then obtained. After several hours at 0° , colourless needles separated. More crystals were obtained by concentration of the mother liquors. The total crude product recrystallised from ethyl alcohol-ether in feathery, colourless needles of 2 : 4-dimethylthiazole-5-acetamide, m. p. 173° . Yield, 0.72 g. (84.3%) (Found : C, 49.4; H, 5.5; N, 17.1. $\text{C}_7\text{H}_{10}\text{ON}_2\text{S}$ requires C, 49.4; H, 5.9; N, 16.5%). On treatment with picric acid, long needles of the picrate were obtained, m. p. 185° (Found : C, 39.4; H, 3.5; N, 17.4. $\text{C}_{13}\text{H}_{13}\text{O}_6\text{N}_3\text{S}$ requires C, 39.1; H, 3.3; N, 17.5%).

2 : 4-Dimethyl-5-cyanomethylthiazole.—2 : 4-Dimethylthiazole-5-acetamide (1.3 g.) was heated with phosphorus oxychloride (freshly distilled; 5 c.c.) on an oil-bath for 45 minutes at 105 – 115° . The phosphorus oxychloride was then removed on a water-bath at 50° under reduced pressure. To the dark syrupy residue, crushed ice was added, then solid sodium carbonate until the solution was alkaline (litmus). The dark brown solution was then exhaustively extracted with ether, the ethereal extract dried (MgSO_4), and the ether removed by evaporation. The crystalline residue was recrystallised from hot water to give needles of 2 : 4-dimethyl-5-cyanomethylthiazole, m. p. 87° . Yield, 1.0 g. (86%) (Found : C, 54.0; H, 4.9; N, 17.8. $\text{C}_7\text{H}_8\text{N}_2\text{S}$ requires C, 55.3; H, 5.2; N, 18.1%). The picrate was obtained as a yellow crystalline solid, m. p. 125° (Found : C, 40.9; H, 3.2. $\text{C}_{13}\text{H}_{11}\text{O}_7\text{N}_3\text{S}$ requires C, 40.9; H, 2.9%).

Reduction of 2 : 4-Dimethyl-5-cyanomethylthiazole.—2 : 4-Dimethyl-5-cyanomethyl thiazole (0.95 g.) was dissolved in methyl alcohol (40 c.c.) and hydrogenated over Raney nickel at room temperature. When approximately the theoretical amount of hydrogen had been absorbed and no further absorption occurred, the catalyst was filtered off and the methyl alcohol evaporated under reduced pressure in an atmosphere of nitrogen. The product decomposed on keeping but was characterised as the dipicrate. A solution of the syrup (0.2 g.) in alcohol was added to a hot concentrated aqueous solution of picric acid (0.6 g.). On cooling, an oil separated, which eventually solidified and recrystallised from hot water in yellow crystals, m. p. 169° . It was 2 : 4-dimethyl-5-2'-aminomethylthiazole dipicrate (Found : C, 37.3; H, 3.0; N, 17.9. $\text{C}_{15}\text{H}_{18}\text{O}_{14}\text{N}_6\text{S}$ requires C, 37.1; H, 2.9; N, 18.2%).

Condensation of Ethyl 2 : 4-Dimethylthiazole-5-acetate Methiodide with *p*-Nitrosodimethylaniline.—Ethyl 2 : 4-dimethylthiazole-5-acetate (1.0 g.) was kept with methyl iodide (100% excess) at room temperature for 24 hours. The methyl iodide was then evaporated under reduced pressure. A yellow oil was obtained which slowly crystallised; it recrystallised from alcohol in colourless prisms, m. p. 133° , which decomposed too rapidly for analytical figures to be obtained.

To an alcoholic solution of ethyl 2 : 4-dimethylthiazole-5-acetate methiodide (crude oil; 1.0 g.) was added an alcoholic solution of *p*-nitrosodimethylaniline (0.5 g.), whereby a bright green solution was obtained. Piperidine (2 drops) was added; the colour changed to reddish brown, and the solution was heated under reflux for 15 minutes; a purple colouration had then developed. On cooling, crystals separated and were filtered off (0.3 g.). The solution was again heated for a further 2 hours, and on cooling, more crystals were obtained (0.2 g.). The crude product was recrystallised from aqueous methyl alcohol, and 4-methyl-5-carboxymethylthiazole-2-aldehyde *p*-dimethylaminoanil methiodide was obtained as a brownish-green crystalline compound with a bluish-green metallic reflex, m. p. 208° . In dilute aqueous or alcoholic solution the crystals gave a deep purple colouration, which was easily discharged by acids and regenerated by alkali (Found : C, 45.9; H, 5.5. $\text{C}_{18}\text{H}_{24}\text{O}_2\text{N}_4\text{S}$ requires C, 45.7; H, 5.1%).

Condensation of Ethyl 2:4-Dimethylthiazole-5-acetate Methiodide with Quinoline Methiodide.—To ethyl 2:4-dimethylthiazole-5-acetate methiodide (crude oil; 1.0 g.) dissolved in ethyl alcohol (10 c.c.) was added an alcoholic solution of quinoline methiodide (1.7 g.; 100% excess) and sodium hydroxide (0.17 g.). The solution was heated under reflux for 30 minutes; a vivid red colouration had then developed. On cooling, a semi-solid product separated, which was recrystallised from methyl alcohol to give 3:4-dimethyl-5-carbomethoxymethyl-2-thiazolonyl-4-quinolylmethane methiodide as dark red crystals with a bright green, metallic reflex, m. p. 200°. Yield, 0.35 g. (Found: C, 50.3; H, 5.1; N, 6.2. $C_{20}H_{23}O_2N_2S$ requires C, 49.8; H, 4.8; N, 5.8%).

The authors wish to express their thanks to Professors W. N. Haworth, F.R.S., and J. L. Simonsen, F.R.S., for their interest, and to the Colonial Products Research Council for financial support.

264. Anhydrides of Polyhydric Alcohols. Part VII.

1:4-3:6-Dianhydro-d- and -l-Iditol.

By L. F. WIGGINS.

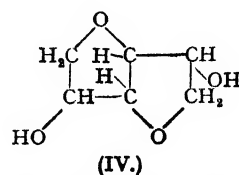

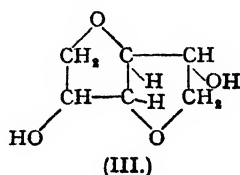

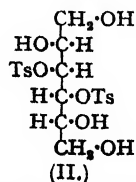

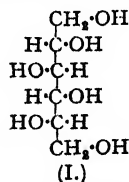

l-Iditol readily undergoes anhydride formation on being heated in the presence of hydrochloric acid, giving 1:4-3:6-dianhydro-*l*-iditol the structure of which is proved by a constitutional synthesis of its enantiomorph.

THE action of acidic reagents on both mannitol and sorbitol gives rise to the dianhydrides of these polyhydric alcohols by internal loss of two molecules of water. Dianhydromannitol, first obtained by Fauconier (*Compt. rend.*, 1882, 95, 991), was shown to possess the constitution of 1:4-3:6-dianhydromannitol by Wiggins in Part I of this series (*J.*, 1945, 4) and by Hockett, Fletcher, Sheffield, Goepf, and Soltzberg (*J. Amer. Chem. Soc.*, 1946, 68, 930). Dianhydrosorbitol, prepared in a similar way to its mannitol analogue, was shown by synthetical methods (Wiggins and Montgomery, *Nature*, 1946, 157, 372; *J.*, 1946, 390) also to have the 1:4-3:6-ring structure. Hockett, Fletcher, Sheffield, and Goepf (*J. Amer. Chem. Soc.*, 1946, 68, 927) have arrived at the same conclusions by different methods.

l-Iditol (I) also undergoes a similar dehydration on being heated in the presence of acids and gives a dianhydride, in the form of a *hemihydrate* which, like the corresponding compounds of mannitol and sorbitol, is stable to treatment with sodium methoxide at 120° under pressure. The *bismethanesulphonyl* and the *dibenzoyl* derivative were readily obtained from it.

By analogy with the dianhydrides of mannitol and sorbitol it would be expected that this compound would also have the hydrofuranol type of ring structure shown in (III). After the completion of this work, Fletcher and Goepf (*J. Amer. Chem. Soc.*, 1945, 67, 1042; 1946, 68, 939) reported that 1:4-3:6-dianhydrosorbitol and dianhydromannitol on dehydrogenation with Raney nickel followed by hydrogenation are both partly converted into dianhydroiditol, and on the assumption that the rings are stable under these conditions, have declared the establishment of the 1:4-3:6-ring structure for all three hexitol dianhydrides. The present paper is concerned with a proof of constitution of the dianhydroiditol along quite different lines. A preliminary note of this appeared in *Nature* (1946, 157, 372).

If mannitol could be tosylated at C_3 and C_4 to give 3:4-ditosyl mannitol (II), this compound on removal of the tosyl groups with sodium methoxide could form only two dianhydrides, (a) 1:3-4:6-dianhydrohexitol, and (b) 1:4-3:6-dianhydrohexitol. Moreover, since it is established in the sugar series that, when hydrolytic removal of tosyl groups is accompanied by anhydro-ring formation, Walden inversion always accompanies the hydrolysis (see Peat, *Ann. Reports*, 1939, 36, 258), it follows that both (a) and (b) would have the configuration of *d*-iditol.

A suitable derivative substituted at C_3 and C_4 with tosyl residues is 3:4-ditosyl 1:2-5:6-diacetone mannitol (Brigl and Gruner, *Ber.*, 1934, 67, 1969). This compound, on partial hydrolysis

followed by acetylation, gave liquid 3:4-ditosyl 1:2:5:6-tetra-acetyl mannitol which on treatment with sodium methoxide gave a crystalline dianhydrohexitol which gave crystalline bis-methanesulphonyl and dibenzoyl derivatives. These had the same melting points as and specific rotation equal, but opposite in sign, to the corresponding derivatives obtained from the product of the anhydroidisation of *l*-iditol. Therefore the two sets of compounds are enantiomorphous, and dianhydro-*d*-iditol and bismethanesulphonyl and dibenzoyl dianhydro-*d*-iditol must have been obtained from mannitol.

The precise constitution of dianhydroiditol is limited to the possibilities (a) and (b) above. Since (a) involves four-membered rings which are extremely unlikely of formation when five-membered rings are possible, and since in (a) the two free hydroxyl groups would approach near enough to be joined in acetal formation by a benzylidene residue, and because dianhydro-iditol does not form such a derivative, structure (b) must be regarded as the correct one. Dianhydro-*d*-iditol is formulated by (III), a representation differing from that of 1:4-3:6-dianhydro-*d*-mannitol (IV) only in the orientation of the two rings.

EXPERIMENTAL.

1-Iditol.—This was prepared from *l*-sorbose by catalytic hydrogenation and separated from the accompanying *l*-sorbitol by fractional crystallisation of the acetyl derivatives (Jones and Wiggins, *J.*, 1944, 363).

Action of Hydrochloric Acid on 1-Iditol.—Crystalline *l*-iditol (5 g.) was boiled under reflux for 50 hours with fuming hydrochloric acid (50 c.c.). The dark brown solution was evaporated to a syrup which was distilled at 150–155° (bath temp.)/0.05 mm. The distillate (3.1 g.) crystallised completely on cooling. It recrystallised in prisms from ethyl acetate (2.3 g.), m. p. 43–45°, $[\alpha]_D^{25} + 18.4^\circ$ (c, 2.389 in water), and was 1:4-3:6-dianhydro-*l*-iditol hemihydrate (Found: C, 46.7, 46.1; H, 7.0, 7.3. $C_8H_{10}O_4 \cdot \frac{1}{2}H_2O$ requires C, 46.5; H, 7.1%).

Treatment of Dianhydro-*l*-iditol with Sodium Methoxide.—The dianhydroiditol (1.7 g.) was heated in a sealed tube with 5% methyl-alcoholic sodium methoxide at 120° for 24 hours. Thereafter, the solution was diluted with water, neutralised with sulphuric acid, and evaporated to dryness, and the residue was extracted with ethyl acetate. The extract was evaporated and the syrupy product distilled at 160°/0.02 mm. The distillate, which completely crystallised, was unchanged 1:4-3:6-dianhydro-*l*-iditol (1.55 g.); it recrystallised from ethyl acetate as the hemihydrate, m. p. 43–45° alone or in admixture with the starting material.

Attempted Condensation of Dianhydro-*l*-iditol with Benzaldehyde.—The dianhydride (0.55 g.) was shaken with freshly distilled benzaldehyde (10 c.c.) and zinc chloride (0.5 g.) for 48 hours. The resulting suspension was poured into water-ligroin which completely dissolved it. Sodium carbonate (0.5 g.), dissolved in water, was added and the mixture distilled under reduced pressure, with addition of water until all the benzaldehyde was removed. After being evaporated to dryness the residue was extracted with ethyl acetate, and the extract evaporated. From ethyl acetate there crystallised unchanged dianhydro-*l*-iditol hemihydrate (0.4 g.), m. p. 43–45° alone or in admixture with the starting material.

2:5-Bismethanesulphonyl 1:4-3:6-Dianhydro-*l*-iditol.—The dianhydride (0.2 g.), dissolved in dry pyridine (5 c.c.), was treated with methanesulphonyl chloride (0.4 g.) at room temperature. The mixture was kept for 24 hours and then poured into ice-water. The crystalline precipitate was collected; the compound recrystallised from alcohol in long needles, m. p. 155–156°, $[\alpha]_D^{25} + 41.9^\circ$ (c, 1.145 in acetone) (Found: C, 32.2; H, 4.9. $C_8H_{14}O_8S_2$ requires C, 31.8; H, 4.6%).

2:5-Dibenzoyl Dianhydro-*l*-iditol.—The dianhydride (0.1 g.) was dissolved in 5*N*-sodium hydroxide (3 c.c.), and benzoyl chloride (0.3 g. added). After vigorous shaking for $\frac{1}{2}$ hour, the solid which had separated was collected and washed with water; the compound recrystallised from alcohol in plates (0.13 g.), m. p. 110–111°, $[\alpha]_D^{25} + 139.1^\circ$ (c, 1.04 in chloroform) (Found: C, 67.7; H, 4.9. $C_{20}H_{18}O_8$ requires C, 67.8; H, 5.1%).

3:4-Ditosyl Tetra-acetyl Mannitol.—3:4-Ditosyl 1:2-5:6-diacetone mannitol (10 g.) (prepared by the method of Brigl and Gruner, *loc. cit.*) was hydrolysed by heating it for 3 hours at 70° with 70% acetic acid (100 c.c.). The acetic acid was removed under reduced pressure. The resulting syrup was acetylated by boiling with acetic anhydride (26 c.c.) and sodium acetate (10 g.). The mixture was poured into water and the product neutralised with sodium bicarbonate and extracted with chloroform. The extract was dried ($MgSO_4$) and evaporated. The compound was a syrup (7.5 g.) which could not be induced to crystallise; $[\alpha]_D^{25} - 0.8^\circ$ (c, 10.23 in chloroform) (Found: S, 9.6. $C_{28}H_{44}O_{14}S_2$ requires S, 9.7%).

Treatment of 3:4-Ditosyl Tetra-acetyl Mannitol with Sodium Methoxide.—The syrup (7.5 g.) was dissolved in chloroform (100 c.c.), and sodium methoxide (4 g.), dissolved in dry methyl alcohol (40 c.c.), added at 0°. The mixture was allowed to warm up to room temperature and to remain thereat for 4 hours. The mixture was extracted with water and separated from the chloroform layer. The aqueous extract was neutralised with *N*-sulphuric acid and the solution evaporated to dryness. The residue was extracted with ethyl acetate, and on evaporation of this solvent a syrup (0.9 g.) was obtained. This distilled at 160° (bath temp.)/0.08 mm. and showed $n_D^{20} 1.4925$, $[\alpha]_D^{25} - 16.7^\circ$ (c, 5.27 in water) (Found: C, 48.8; H, 6.8. $C_8H_{10}O_4$ requires C, 49.3; H, 6.8%). The product crystallised but it was not possible to recrystallise it.

2:5-Dibenzoyl 1:4-3:6-Dianhydro-*d*-iditol.—The above distillate (0.8 g.) was dissolved in 5*N*-sodium hydroxide; benzoyl chloride (2 c.c.) was added, and the mixture shaken vigorously for $\frac{1}{2}$ hour. The dibenzoyl derivative was collected, washed with water, and recrystallised from alcohol. Yield, 0.94 g.; m. p. 110–111°; $[\alpha]_D^{25} - 138.6^\circ$ (c, 3.475 in chloroform) (Found: C, 68.0; H, 5.2. $C_{20}H_{18}O_8$ requires C, 67.8; H, 5.1%).

2 : 5-Bismethanesulphonyl 1 : 4-3 : 6-Dianhydro-d-*iditol*.—Dianhydro-*d*-*iditol* (0.3 g.) was dissolved in dry pyridine (6 c.c.) and methanesulphonyl chloride (0.8 g.) added at 0°. The mixture was kept at room temperature for 74 hours and was then poured into ice-water, and the solid which had separated was collected and washed with water; the compound recrystallised from alcohol in the form of needles. Yield, 0.25 g.; m. p. 156°; $[\alpha]_D^{25} - 41.2^\circ$ (c, 1.41 in acetone) (Found: C, 32.1; H, 4.3. $C_8H_{14}O_8S_2$ requires C, 31.8; H, 4.6%).

Fletcher and Goepf (*loc. cit.*) give, for anhydrous dianhydro-*l*-*iditol*, m. p. 63.7—64.5°, $[\alpha]_D + 20.8^\circ$ (in water), and for the dibenzoate, m. p. 111—111.3°, $[\alpha]_D + 141.9^\circ$ (in chloroform).

The author is grateful to Sir Norman Haworth, F.R.S., for his interest in this work, and to the Colonial Products Research Council for financial aid.

[Received, December 24th, 1946.]

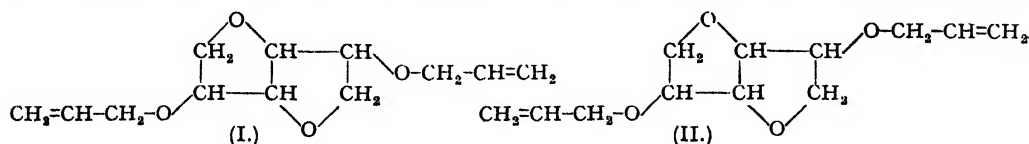

265. Anhydrides of Polyhydric Alcohols. Part VIII. Some Alkenyl Ethers of 1 : 4-3 : 6-Dianhydromannitol and 1 : 4-3 : 6-Dianhydrosorbitol.

By HILDA GREGORY and L. F. WIGGINS.

Diallyl and dimethallyl ethers of the 1 : 4-3 : 6-dianhydrides of mannitol and sorbitol have been prepared. They polymerise slowly in a stream of oxygen, the allyl at a greater rate than the methallyl ethers.

IN continuation of our studies of 1 : 4-3 : 6-dianhydro-mannitol and -sorbitol described in Parts I and IV—VII of this series, we have sought to obtain unsaturated ethers of these compounds. In a previous communication (Haworth, Gregory, and Wiggins, *J.*, 1946, 488) we have described unsaturated acyl derivatives of these dianhydrides, namely the diacrylyl and dimethacrylyl esters, which were found to polymerise very rapidly to glass-like resins; saturated ether derivatives have also been reported (Haworth and Wiggins; Patent Application 1945).

The allyl ethers of certain carbohydrates have recently been obtained by Nichols and Yanovsky and their associates; these include allyl sucrose (Nichols and Yanovsky, *J. Amer. Chem. Soc.*, 1945, **67**, 47), tetra-allyl α -methylglucoside (*idem, ibid.*, 1944, **66**, 1625), and allyl starch (Nichols, Hamilton, Smith, and Yanovsky, *Ind. Eng. Chem.*, 1945, **37**, 206). By treating 1 : 4-3 : 6-dianhydro-mannitol and -sorbitol with allyl bromide and concentrated sodium hydroxide solution according to the procedure of Nichols and Yanovsky, we have obtained 2 : 5-diallyl 1 : 4-3 : 6-dianhydromannitol (I) and 2 : 5-diallyl 1 : 4-3 : 6-dianhydrosorbitol (II), complete allylation being accomplished in one treatment, giving 70% yields of the

products. Both compounds were yellow liquids, quite stable to distillation. Although they polymerised slowly in a stream of oxygen, no appreciable effect was observed on heating them in the presence of benzoyl peroxide, a fact previously noted by Nichols and Yanovsky for tetra-allyl α -methylglucoside. The rates of polymerisation of the dianhydrohexitol derivatives at 97° have been followed viscometrically in an Ostwald viscometer modified as shown in Fig. 1, so that oxygen could be bubbled through the substance and the viscosity measured in the same apparatus.

Preliminary experiments showed that the rate of polymerisation depended upon the rate of flow of oxygen through the apparatus, hence the flow of gas was kept constant throughout the polymerisation. It was found that the rate of polymerisation as measured by the viscosity for both the mannitol and the sorbitol derivatives (see Fig. 2) followed closely the behaviour of tetra-allyl α -methylglucoside, described by Nichols and Yanovsky (*loc. cit.*). Fig. 2 shows that the polymerisation of the mannitol derivative was very slightly faster than that of its sorbitol analogue. Both liquids became darker at the beginning of the heating, but became progressively lighter in colour as the polymerisation continued. The viscosity increased slowly for about 180 minutes, followed by a rapid increase to the gelation point, at which the substances were almost colourless. Both end-products were soft and rubbery, completely infusible and insoluble.

On treatment of dianhydromannitol with methallyl chloride and concentrated sodium hydroxide solution at ordinary pressures, 2 : 5-dimethallyl 1 : 4-3 : 6-dianhydromannitol was obtained in poor yield, owing probably to loss of reagent and incompleteness of reaction. Some improvement was effected by carrying out the reaction in an autoclave fitted with a stirring device, and by this method 2 : 5-dimethallyl-1 : 4-3 : 6-dianhydrosorbitol was obtained. Both of the methallyl derivatives were yellow liquids which polymerised slowly on being heated in a stream of oxygen. Neither, however, gelatinised, or reached a state of acetone insolubility, as distinct from the behaviour of the corresponding allyl derivatives. The rates of polymerisation (see Fig. 2) when investigated under the same conditions as described previously were also markedly slower than those of the allyl ethers; even after 24 hours at 97° in a stream of oxygen at 10 l./hour, no gel formation had occurred and the viscous liquid remained acetone soluble.

FIG. 2.

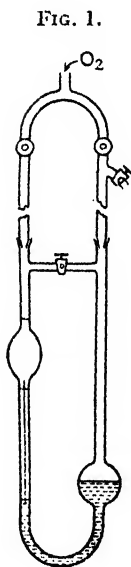

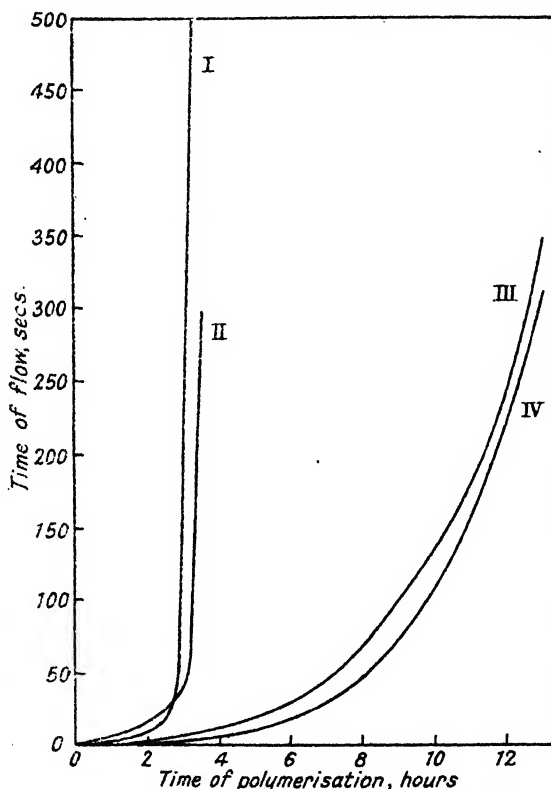

FIG. 1.

- I. 2 : 5-Diallyl 1 : 4-3 : 6-dianhydromannitol.
 II. 2 : 5-Diallyl 1 : 4-3 : 6-dianhydrosorbitol.
 III. 2 : 5-Dimethallyl 1 : 4-3 : 6-dianhydrosorbitol.
 IV. 2 : 5-Dimethallyl 1 : 4-3 : 6-dianhydromannitol.

The difference in the rates of polymerisation of the allyl and methallyl ethers and the difference in properties of the final product must be due to the presence of the methyl group. Therefore, since the methallyl ethers polymerise more slowly and to a lesser degree than the allyl ethers, the methyl group must exhibit an inhibitory effect upon polymerisation. This tendency has been observed previously in many cases. For instance, whereas styrene will undergo addition polymerisation very rapidly, to form long-chain macromolecules, α -methylstyrene will only form an octamer (Staudinger and Breusch, *Ber.*, 1929, 62, 442), and β -methylstyrene, dimeric molecules (Errera, *Gazzetta*, 1884, 14, 504).

EXPERIMENTAL.

2 : 5-Diallyl 1 : 4-3 : 6-Dianhydrosorbitol.—Dianhydrosorbitol (50 g.) was suspended in allyl bromide (85 c.c.) in a three-necked bolthead flask, fitted with a dropping funnel, condenser, and mechanical

stirring device. The well-stirred reaction mixture was maintained at 70°. Sodium hydroxide solution (53 c.c. of a 52% solution, w/v) was added slowly during 1.25 hours, and stirring continued for a further 1.75 hours. Water (100 c.c.) was then added, and any unsaturated volatile compounds present were removed by steam distillation. The mixture was then extracted with ether, the ethereal extract washed with water and dried (MgSO_4), and the ether removed, leaving a light brown, mobile liquid. This was fractionally distilled under reduced pressure in an atmosphere of carbon dioxide. The bulk distilled at 157–161°/20 mm. One further distillation gave pure *diallyl dianhydrosorbitol* as a colourless liquid in 70.3% yield, b. p. 185°/40 mm., n_D^{20} 1.4812, $[\alpha]_D^{20} + 93.4^\circ$ (c, 1.756 in chloroform) (Found: C, 63.4; H, 7.7. $\text{C}_{12}\text{H}_{18}\text{O}_4$ requires C, 63.6; H, 8.0%).

The rate of polymerisation of 2:5-diallyl dianhydrosorbitol was followed viscometrically. The results below give the time of flow in seconds for the corresponding time of polymerisation in minutes (in parentheses): 1.9 (0); 2.4 (20); 2.8 (45); 18 (130); 37.0 (166); 118.0 (196); 160 (205); 245.0 (210); ∞ (216). During the last reading the material gelled in the tube. These results are shown graphically in Fig. 2.

2:5-Diallyl 1:4:3:6-Dianhydromannitol.—This was prepared on the same scale and in the same way as its sorbitol analogue. The compound was obtained as a colourless, mobile liquid, b. p. 173°/10 mm., n_D^{20} 1.4847, $[\alpha]_D^{20} + 160.3^\circ$ (c, 1.51 in chloroform) (Found: C, 63.2; H, 8.3. $\text{C}_{12}\text{H}_{18}\text{O}_4$ requires C, 63.6; H, 8.0%).

The rate of polymerisation of 2:5-diallyl dianhydromannitol was investigated viscometrically. The following results give the time of flow in seconds for the corresponding time of polymerisation in minutes (in parentheses): 1.4 (0); 1.8 (20); 2.4 (80); 5.6 (105); 15.1 (135); 32.4 (155); 82.0 (170); 120.0 (180); 495.2 (185); ∞ (193). These results are shown graphically in Fig. 2.

2:5-Dimethylallyl 1:4:3:6-Dianhydromannitol.—A mixture of 1:4:3:6-dianhydromannitol (20.0 g.), methallyl chloride (100 c.c.), and sodium hydroxide (22 c.c. of a 52% solution, w/v) was heated on a boiling water-bath for 10 hours. The mixture was kept well stirred throughout the reaction to prevent the conversion of methallyl chloride into isobutaldehyde as a result of the development of local acidity. The mixture was then cooled, water (200 c.c.) was added, and the two layers were separated. The upper layer was dried (CaCl_2) and distilled on a boiling water-bath under reduced pressure to remove the more volatile components. The residual oil was fractionally distilled under reduced pressure in an atmosphere of carbon dioxide. The bulk distilled at 132–135°/10 mm. as a pale yellow liquid which darkened on standing. One further distillation under the same conditions gave 2:5-dimethylallyl 1:4:3:6-dianhydromannitol (4.62 g.), b. p. 135°/10 mm., n_D^{20} 1.4979, $[\alpha]_D^{20} + 71.4^\circ$ (c, 1.168 in chloroform) (Found: C, 66.0; H, 8.3. $\text{C}_{14}\text{H}_{22}\text{O}_4$ requires C, 66.1; H, 8.6%). The rate of polymerisation of 2:5-dimethylallyl 1:4:3:6-dianhydromannitol was investigated viscometrically. The following results give the time of flow in seconds for the corresponding time of polymerisation in minutes (in parentheses): 2.5 (0); 3.0 (60); 4.0 (120); 2 (150); 5.8 (195); 8.0 (240); 11.2 (300); 18.0 (360); 27.8 (420); 35.0 (450); 52.2 (480); 1400 (990). Further readings could not be taken owing to the high viscosity of the liquid. These results are shown graphically in Fig. 2.

2:5-Dimethylallyl 1:4:3:6-Dianhydrosorbitol.—Dianhydrosorbitol (20 g.), methallyl chloride (100 g.), sodium hydroxide solution (22 c.c. of a 50% solution, w/v), and acetone (100 c.c.) were heated in a stainless steel autoclave, fitted with a stirring device, for 10 hours at 120°. The contents of the autoclave were then diluted with water (200 c.c.) and the mixture was steam distilled to remove acetone, methallyl chloride, and any methallyl alcohol and dimethylallyl ether produced during the reaction. The remaining liquid was then cooled and extracted with ether, the ethereal extract was washed with water and dried (MgSO_4), and the ether was removed. The residual brown mobile liquid was fractionally distilled under reduced pressure in an atmosphere of carbon dioxide, whereby a pale yellow liquid was obtained, b. p. 150–160°/15 mm. The distillate was then redistilled using the same precautions; dimethylallyl dianhydrosorbitol (6.4 g.) was obtained, b. p. 157°/15 mm., n_D^{20} 1.4843, $[\alpha]_D^{20} + 37.1^\circ$ (c, 1.40 in chloroform) (Found: C, 66.0; H, 8.7. $\text{C}_{14}\text{H}_{22}\text{O}_4$ requires C, 66.1; H, 8.66%).

The rate of polymerisation of 2:5-dimethylallyl dianhydrosorbitol was followed viscometrically. The results below give the time of flow in seconds for the corresponding time of polymerisation in minutes (in parentheses): 1.9 (0); 2.6 (60); 14.4 (255); 20.5 (295); 26.6 (330); 30.0 (360); 36.4 (390); 44.0 (420); 52.0 (440); 64.5 (475); 85.0 (515); 88.6 (540); 123.0 (570); 133.0 (600); 195.0 (675); 315.0 (750); 581.0 (810); 1423 (970). Further readings could not be taken in this apparatus owing to the high viscosity of the liquid. The results are shown graphically in Fig. 2.

The authors wish to express their thanks to Sir Norman Haworth, F.R.S., and Dr. J. L. Simonsen, F.R.S., for their interest, and to the Colonial Products Research Council for financial assistance.

266. The Preparation of 1:8-Naphthyridines from 2:6-Diaminopyridine.

By V. PETROW, E. L. REWALD, and B. STURGEON.

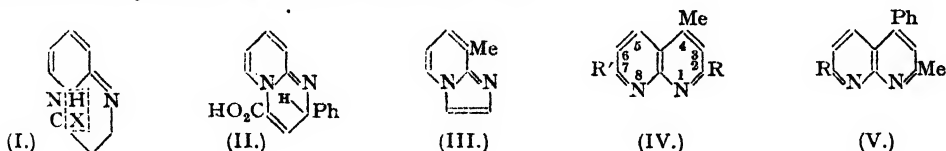

7-Amino-2-hydroxy-4-methyl-1:8-naphthyridine (IV; $\text{R} = \text{OH}$, $\text{R}' = \text{NH}_2$), prepared by condensation of ethyl acetoacetate or ethyl β -aminocrotonate with 2:6-diaminopyridine, has been converted into 2-chloro-7-acetamido-4-methyl-1:8-naphthyridine (IV; $\text{R} = \text{Cl}$, $\text{R}' = \text{NHAc}$), and hence into 2-anilino-, 2-p-chloroanilino-, 2-piperidino-, and 2-phenoxy-7-amino-4-methyl-1:8-naphthyridine.

Condensation of benzoylacetone with 2:6-diaminopyridine gives 7-amino-4-phenyl-2-methyl-1:8-naphthyridine (V; R = NH₂), converted into 7-hydroxy-, 7-chloro-, and hence into 7-anilino-, 7-piperidino-, and 7-phenoxy-4-phenyl-2-methyl-1:8-naphthyridine. (V; R = NHAc) gives the 1(N)-monoquaternary salt.

Our interest in the naphthyridines arose from the chance observation that certain members of the series possessed valuable biological properties (see Petrow, *J.*, 1946, 200), and a comprehensive survey of the field is now in progress in these Laboratories. The present communication describes some new derivatives of 1:8-naphthyridine. Biological data will be reported elsewhere.

Although 2-aminopyridine would appear to form the obvious starting point for the synthesis of 1:8-naphthyridines, they have not hitherto been prepared from this base. Earlier claims to this effect by Reissert (*Ber.*, 1895, 28, 119) and R  th (*Annalen*, 1931, 486, 284; see also E.P.P. 319,974, 339,932 and G.P.P. 526,630, 522,272) have been conclusively disproved by Bose and Sen (*J.*, 1931, 2840), Seide and Chelinzwen (*J. Gen. Chem. Russia*, 1937, 7, 2314), Sp  th and Kuffner (*Ber.*, 1938, 71, 1657), and Petrow (*J.*, 1945, 928). It would appear that 2-aminopyridine reacts preferentially in the imino-form [partial formula (I)] to give the pyrimidine ring system such as (II) in cases of ring closure. Reactions with ethyl acetoacetate (Crippa and Scevola, *Gazzetta*, 1937, 67, 330), ethyl benzoylacetate (Seide, *Ber.*, 1925, 58, 352; cf. Palazzo and Tamburini, *Atti R. Accad. Lincei*, 1911, 20, I, 37), ethyl malonate (Tschitschibabin, *Ber.*, 1924, 57, 1169), and ethylene oxide (Kunzjanz, *Ber.*, 1935, 68, 397) have been shown to fall into this category. The recent claim of Mazza and Migliardi (*Atti R. Accad. Sci. Torino*, 1940, 75, I, 438; see also Migliardi, *ibid.*, p. 548) that reaction of 2-aminopyridine with benzaldehyde and pyruvic acid leads to a 4-carboxy-2-phenyl-1:8-naphthyridine cannot be accepted. There seems little doubt that their product should be correctly formulated as the pyrimidine derivative (II). R  th (*Ber.*, 1925, 58, 347; cf. Tschitschibabin, *ibid.*, p. 1704) has described the formation of a "1:2-dihydro-1:8-naphthyridine" in low yield from the products of reaction of 2-amino-3-methylpyridine with bromoacetal at 250  . This claim, too, must be accepted with caution, as it seems unreasonable to assume the stability of a 1:2-dihydro-structure under the conditions of the experiment. In our view, this reaction leads to the 8-methylpyrimidazole (III). The facile formation of ring systems of this type has been demonstrated by Schmidt and Bangler (*Ber.*, 1926, 59, 1360), Tschitschibabin (*loc. cit.*), and Allen *et al.* (*J. Amer. Chem. Soc.*, 1944, 66, 1805). 2-Aminopyridine behaves as a cyclic amidine in these reactions, and on electro-chemical grounds alone its conversion into a 1:8-naphthyridine appears highly improbable.

2:6-Diaminopyridine, in striking contrast to 2-aminopyridine, forms the most accessible starting material for the synthesis of 1:8-naphthyridines, owing probably to the presence of two amino-groupings in the molecule either of which can take part in the prototropic change involved in imine-formation. By direct condensation of the base with ethyl acetoacetate, Seide (*Ber.*, 1926, 59, 2465) obtained 7-amino-2-hydroxy-4-methyl-1:8-naphthyridine (IV; R = OH, R' = NH₂) in good yield. The reaction has been extended to ethyl benzoylacetate (Mangini and Colonna, *Gazzetta*, 1942, 72, 183), acetylacetone (Mangini, *Chem. Zentr.*, 1940, II, 2613; Ochiai and Miyaki, *Ber.*, 1941, 74, 1115), and ethoxymethylene diethylmalonate (Adams *et al.*, *J. Amer. Chem. Soc.*, 1946, 68, 1317).

We now find that 7-amino-2-hydroxy-4-methyl-1:8-naphthyridine (IV; R = OH, R' = NH₂) (Seide, *loc. cit.*) passes smoothly under the action of acetic anhydride into 7-acetamido-2-hydroxy-4-methyl-1:8-naphthyridine (Mangini and Colonna, *loc. cit.*). The acetamidogrouping in this compound proved stable to phosphorus oxychloride, giving 2-chloro-7-acetamido-4-methyl-1:8-naphthyridine (IV; R = Cl, R' = NHAc), occasionally mixed with some 2-chloro-7-amino-4-methyl-1:8-naphthyridine. Treatment of (IV; R = Cl, R' = NHAc) with phenol at 180   gave 7-acetamido-2-phenoxy-4-methyl-1:8-naphthyridine, hydrolysed to the corresponding amino-derivative. 7-Amino-2-anilino-, 7-amino-2-p-chloroanilino-, and 7-amino-2-piperidino-4-methyl-1:8-naphthyridine were similarly prepared.

Condensation of 2:6-diaminopyridine with benzoylacetone in the presence of zinc chloride

gave 7-amino-4-phenyl-2-methyl-1 : 8-naphthyridine (V; R = NH₂), characterised by preparation of the *picrate*. The derived acetamido-compound (V; R = NHAc) was converted *via* the methosulphate into 7-acetamido-4-phenyl-2-methyl-1 : 8-naphthyridine-1-methiodide, and hence into the corresponding methochloride. The constitution assigned to the monomethiodide followed from the formation of a highly coloured dye on heating the compound with *p*-dimethylaminobenzaldehyde in alcoholic solution containing a trace of piperidine. This colour change is almost certainly due to the formation of the corresponding 2-*p*-dimethylamino-styryl derivative, but attempts to isolate it in a state of analytical purity were unsuccessful. Treatment of (V; R = NH₂) with nitrous acid gave 7-hydroxy-4-phenyl-2-methyl-1 : 8-naphthyridine (V; R = OH), from which 7-chloro-, and hence 7-phenoxy-, 7-anilino-, and 7-piperidino-4-phenyl-2-methyl-1 : 8-naphthyridine were readily prepared. Attempts to condense (V; R = NH₂) with *p*-acetamidobenzenesulphonyl chloride were unsuccessful.

We have *inter alia* examined the condensation of ethyl β -aminocrotonate with 2 : 6-diaminopyridine in the hope of obtaining the isomeric 7-amino-4-hydroxy-2-methyl-1 : 8-naphthyridine, but the only product isolated as (IV; R = OH, R' = NH₂) in somewhat better yield. The corresponding nitrile, β -aminocrotononitrile, it may be added, reacts with arylamines with exceptional facility to give the β -aryliminobutyronitriles by loss of the elements of ammonia (Meyer, *J. pr. Chem.*, 1908, 78, 499). Its behaviour with the aminopyridines will form the subject of a later communication.

EXPERIMENTAL.

(M. p.s are corrected. Microanalyses are by Drs. Weiler and Strauss, Oxford.)

2-Chloro-7-acetamido-4-methyl-1 : 8-naphthyridine (IV; R = Cl, R' = NHAc).—7-Acetamido-2-hydroxy-4-methyl-1 : 8-naphthyridine was prepared by heating finely powdered (IV; R = OH, R' = NH₂) (Seide, *Ber.*, 1926, 59, 2465) (2 g.) with acetic anhydride (30 ml.) under reflux for 30 mins. The heavy yellow solid changed to a flocculent white suspension. When cold, the product was collected and recrystallised from a large volume of glacial acetic acid (charcoal), giving white crystals, m. p. >310° (Found: C, 60.8; H, 5.2; N, 19.0. Calc. for C₁₁H₁₁O₂N₃ C, 60.8; H, 5.1; N, 19.3%). Yield 2.2 g. (89%) (Mangini and Colonna, *loc. cit.*, give m. p. <285°). The acetamido-compound (10 g.) was heated with phosphorus oxychloride (100 ml.) for 30 minutes under reflux. The product was decomposed with ice-water and made alkaline with sodium hydroxide, and the precipitated solids were recrystallised from spirit. 2-Chloro-7-acetamido-4-methyl-1 : 8-naphthyridine formed felted white needles (7.5 g.; 69%), m. p. 240° (Found: C, 55.9; H, 3.8; N, 17.8; Cl, 15.6. C₁₁H₁₀ON₂Cl requires C, 56.1; H, 4.2; N, 17.8; Cl, 15.1%).

If the temperature rose somewhat during the decomposition of the phosphorus oxychloride reaction mixture, 2-chloro-7-amino-4-methyl-1 : 8-naphthyridine, white needles, m. p. 258–259°, from alcohol (Found: Cl, 21.3. C₉H₇N₃Cl requires Cl, 21.7%), was also obtained, readily separated from the acetamido-compound by fractionation from alcohol in which it was less soluble. On acetylation it gave the acetamido-derivative, m. p. 240° (above).

7-Acetamido-2-phenoxy-4-methyl-1 : 8-naphthyridine.—2-Chloro-7-acetamido-4-methyl-1 : 8-naphthyridine (1 g.) was heated with phenol (3 g.) at 180° for 1 hour. The cooled melt was treated with excess of sodium hydroxide solution, and the insoluble fraction collected and heated with acetic anhydride on the water-bath. 7-Acetamido-2-phenoxy-4-methyl-1 : 8-naphthyridine, separated on cooling as long needles from aqueous alcohol, m. p. 205° (Found: C, 69.3; H, 5.2; N, 14.1. C₁₇H₁₅O₂N₃ requires C, 69.6; H, 5.1; N, 14.3%). Hydrolysis with alcoholic hydrochloric acid gave 7-amino-2-phenoxy-4-methyl-1 : 8-naphthyridine, needles from benzene, m. p. 216–217° (Found: C, 71.6; H, 5.3; N, 16.7. C₁₅H₁₃ON₃ requires C, 71.8; H, 5.2; N, 16.7%).

7-Amino-2-anilino-4-methyl-1 : 8-naphthyridine (IV; R = NHPh, R' = NH₂).—2-Chloro-7-acetamido-4-methyl-1 : 8-naphthyridine (4 g.) was heated with aniline (10 ml.) under reflux for 3 hours. Excess of aniline was removed in steam, and the solids were collected and heated under reflux with 2*N*-hydrochloric acid for 1 hour. The mixture was made alkaline with sodium hydroxide and the product purified from spirit. 7-Amino-2-anilino-4-methyl-1 : 8-naphthyridine formed yellow crystals, m. p. 269–270° (Found: C, 71.6; H, 5.4; N, 23.0. C₁₅H₁₄N₄ requires C, 72.0; H, 5.6; N, 22.4%).

7-Amino-2-*p*-chloroanilino-4-methyl-1 : 8-naphthyridine.—2-Chloro-7-acetamido-4-methyl-1 : 8-naphthyridine (2.5 g.) and *p*-chloroaniline (2.5 g.) were heated under reflux in nitrobenzene (25 ml.). Vigorous reaction occurred in a few minutes and the mixture set to a semi-solid. Heating at 200° was continued for one hour. The yellow-brown solids were collected and crystallised from alcohol-light petroleum. 7-Amino-2-*p*-chloroanilino-4-methyl-1 : 8-naphthyridine formed ivory needles (1 g.; 33%), m. p. 224–225° (Found: C, 63.1; H, 4.9; N, 19.5; Cl, 12.5. C₁₄H₁₃N₄Cl requires C, 63.3; H, 4.6; N, 19.7; Cl, 12.5%). The hydrochloride formed yellow needles from alcohol-light petroleum, m. p. >300° (Found: Cl, 22.8. C₁₄H₁₃N₄Cl₂ requires Cl, 22.9%).

7-Amino-2-piperidino-4-methyl-1 : 8-naphthyridine.—(IV; R = Cl, R' = NHAc) (1 g.) was heated with piperidine (5 ml.) at 180° for 8 hours in a sealed tube. Excess of piperidine was removed on the water-bath. The crystalline product, after hydrolysis with concentrated hydrochloric acid (10 ml.) and alcohol (25 ml.) for 1 hour, followed by basification with sodium hydroxide, gave 7-amino-2-piperidino-4-methyl-1 : 8-naphthyridine, ivory crystals from light petroleum, m. p. 221.5–222.5° (Found: C, 69.0; H, 7.2; N, 22.7. C₁₄H₁₅N₄ requires C, 69.4; H, 7.4; N, 23.1%).

7-Amino-4-phenyl-2-methyl-1 : 8-naphthyridine (V; R = NH₂).—2 : 6-Diaminopyridine (20 g.), benzoylacetone (30 g.), and powdered anhydrous zinc chloride (12 g.) were heated in an oil-bath. Reaction

commenced at 135°, after which the temperature was slowly raised to 175° over 3½ hours. Solution in alcohol (200 ml.) followed by gradual precipitation with water (300 ml.) gave a granular product, further purified by solution in 2*N*-hydrochloric acid (charcoal) and precipitation with sodium hydroxide. For purification, the crude naphthylidine (8 g.) and acetic anhydride (80 ml.) were heated under reflux for 30 minutes. 7-Acetyl-4-phenyl-2-methyl-1:8-naphthylidine, needles from benzene (30%), m. p. 207–208° (Found: C, 73.4; H, 5.4; N, 15.0. $C_{17}H_{15}ON_2$ requires C, 73.6; H, 5.4; N, 15.2%), separated on cooling. Hydrolysis with boiling 15% hydrochloric acid for 30 minutes gave 7-amino-4-phenyl-2-methyl-1:8-naphthylidine, pale yellow octahedra from nitrobenzene, m. p. 247.5–248.5° (Found: C, 76.4; H, 5.6; N, 18.1. $C_{18}H_{17}N_3$ requires C, 76.6; H, 5.5; N, 17.9%), characterised as the *picrate*, fine yellow needles from a large volume of alcohol, m. p. 284° (decomp.) (Found: N, 18.1. $C_{18}H_{13}N_3 \cdot C_6H_3O_7N_3$ requires N, 18.1%).

7-Acetyl-4-phenyl-2-methyl-1:8-naphthylidine-1-(*N*)-methiodide, prepared via the methosulphate, formed silky yellow needles (75%) from alcohol, m. p. 244–245° (Found: I, 31.2. $C_{18}H_{15}ON_2I$ requires I, 30.4%). The methochloride formed pale green platelets from alcohol-ether, m. p. 235–236° (Found: Cl, 11.1. $C_{18}H_{15}ON_2Cl$ requires Cl, 10.8%).

7-Hydroxy-4-phenyl-2-methyl-1:8-naphthylidine (V; R = OH).—The amino-compound (V; R = NH_2) (10 g.) in water (250 ml.) and concentrated hydrochloric acid (5 ml.), mechanically stirred at 0°, was treated simultaneously during 30 minutes with sodium nitrite (4.5 g. in 20 ml. water) and hydrochloric acid (10 ml. in 30 ml. water). After 2 hours the mixture was heated on the water-bath until evolution of nitrogen had ceased. The product was precipitated with ammonium hydroxide (d 0.88), giving 7-hydroxy-4-phenyl-2-methyl-1:8-naphthylidine, needles from alcohol, m. p. 252–253° (Found: C, 76.3; H, 5.2; N, 11.6. $C_{18}H_{17}ON_2$ requires C, 76.2; H, 5.1; N, 11.9%). The compound dissolves in sodium hydroxide solution.

7-Chloro-4-phenyl-2-methyl-1:8-naphthylidine (V; R = Cl).—The hydroxy-compound (V; R = OH) (2 g.) and phosphorus oxychloride (15 ml.) were heated under reflux at 140–150° for 30 minutes. The product, isolated in the usual way, gave 7-chloro-4-phenyl-2-methyl-1:8-naphthylidine (70%), felted needles from aqueous methanol (charcoal), m. p. 161° (Found: Cl, 14.4. $C_{18}H_{15}N_2Cl$ requires Cl, 14.0%).

7-Phenoxy-4-phenyl-2-methyl-1:8-naphthylidine separated from benzene–light petroleum in needles (80%), m. p. 156–157.5° (Found: C, 80.6; H, 5.3; N, 8.9. $C_{21}H_{19}ON_2$ requires C, 80.7; H, 5.2; N, 8.9%).

7-Anilino-4-phenyl-2-methyl-1:8-naphthylidine formed pale yellow needles from a large volume of alcohol, m. p. 286–287° (Found: C, 80.4; H, 5.6; N, 13.3. $C_{21}H_{17}N_3$ requires C, 81.0; H, 5.5; N, 13.5%).

7-Piperidino-4-phenyl-2-methyl-1:8-naphthylidine, isolated as the *picrate*, long yellow needles from alcohol, m. p. 220–221° (decomp. at 238°) (Found: N, 15.7. $C_{20}H_{21}N_3 \cdot C_6H_3O_7N_3$ requires N, 15.8%), formed pale yellow plates from benzene–light petroleum, m. p. 131–132° (Found: C, 79.0; H, 7.0; N, 14.0. $C_{20}H_{21}N_3$ requires C, 79.2; H, 6.9; N, 13.9%).

7-Amino-2-hydroxy-4-methyl-1:8-naphthylidine (IV; R = OH, R' = NH_2).—2:6-Diaminopyridine (5 g.) and ethyl β-aminocrotonate (6 g.) were heated at 180–200° for 2 hours, after which the temperature was raised to 220° during 45 minutes, the mixture then solidifying. The grey-green mass was extracted with alcohol, giving (IV; R = OH, R' = NH_2), m. p. >360°, identified by acetylation and chlorination to (IV; R = Cl, R' = $NHAc$), m. p. 240°, alone or in admixture with an authentic specimen (above), further converted into (IV; R = *OPh*, R' = NH_2), m. p. 214–215°, alone or in admixture with an authentic specimen.

The authors thank the Therapeutic Research Corporation of Great Britain Limited for grants and for certain facilities.

QUEEN MARY COLLEGE (UNIVERSITY OF LONDON), E.1.

[Received, December 31st, 1946.]

267. Contributions to the Chemistry of Phenanthridine. Part I. The Conversion of 9-(3'-Pyridyl)phenanthridines into their Quaternary Salts and the Preparation of Some Derivatives of Potential Biological Interest.

By V. PETROW and W. R. WRAGG.

9-(3'-Pyridyl)- (II; R = R' = H), 3-nitro-9-(3'-pyridyl)- (II; R = NO_2 , R' = H), and 7-nitro-9-(3'-pyridyl)-phenanthridine (II; R = H, R' = NO_2) have been obtained from the appropriate 2-nicotinamidodiphenyls. Conversion of the first two compounds into their mono-quaternary salts led to the formation of the py-N-methylmethosulphates, the constitution of which followed from their oxidation to the corresponding N-methylpyridones.* As expected, the monomethiodide derived from 9-(6'-keto-1'-methyl-1':6'-dihydro-3'-pyridyl)phenanthridine (IV; R = H) possessed the anticipated properties of a phenanthridyl-N-methiodide.

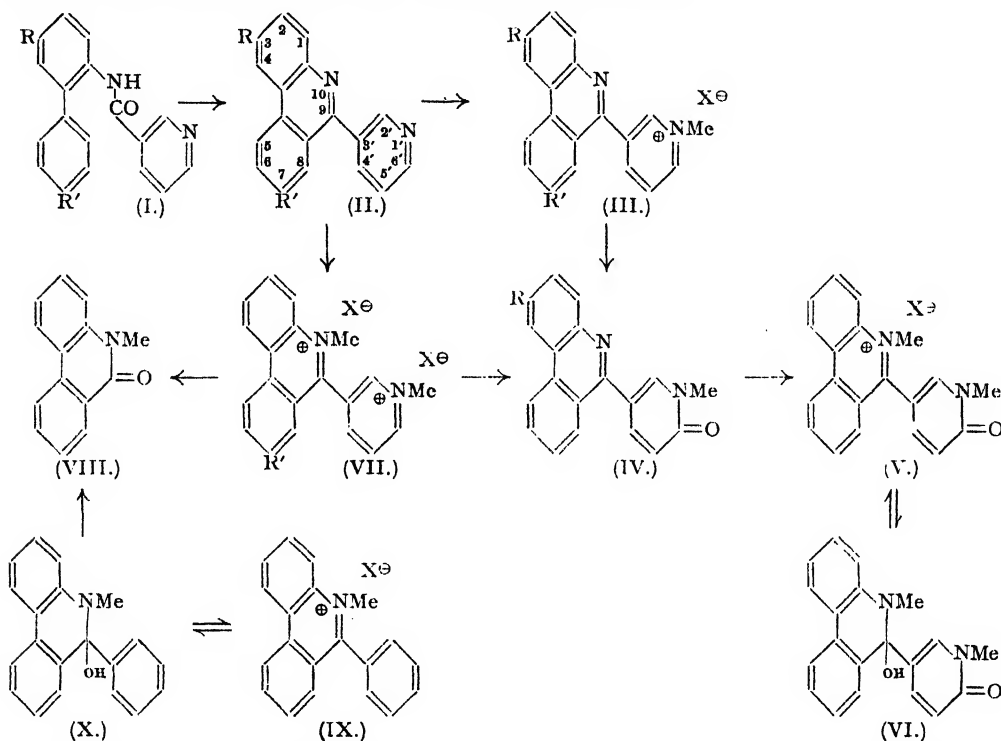

Treatment of 9-(3'-pyridyl)phenanthridine 1':10-dimethiodide (VII; R' = H, X = I) with excess of aqueous sodium hydroxide followed by potassium ferricyanide at room temperature gave (IV; R = H). Reaction with boiling alcoholic sodium hydroxide, however, resulted in

* These N-methylpyridones may clearly be either 2'- or 6'-pyridones. The question is irrelevant to the present investigation and the orientation of a 6'-pyridone has been assumed throughout.

loss of the pyridyl-1'-methiodide grouping and the production of 10-methyl-9-phenanthridone (VIII), also obtained by the action of alcoholic alkaline ferricyanide on 9-phenylphenanthridine 10-methylmethosulphate (IX; X = MeSO₃).

Reduction of the two nitro-9-(3'-pyridyl)phenanthridines (II; R = NO₂, R' = H, and R = H, R' = NO₂) and their py-N-methylmethosulphates gave the corresponding amino-compounds.

FOLLOWING recent work on the relationship between structure and biological activity in the phenanthridine series (Petrov, *J.*, 1945, 18; Walls, *ibid.*, p. 294), we have now synthesised some 9-(3'-pyridyl)phenanthridines. We required these for examination as trypanocides, and also, from their formal analogy to the pyridyl quinolines of Coates, Cook, Heilbron, Hey, Lambert, and Lewis (*J.*, 1943, 401), for study as spasmolytics.

Condensation of nicotinyl chloride hydrochloride with 2-aminodiphenyl in boiling chlorobenzene solution led to the formation of 2-nicotinamidodiphenyl (I; R = R' = H) in 78% yield. 5-Nitro- (I; R = NO₂, R' = H), and 4'-nitro-2-nicotinamidodiphenyl (I; R = H, R' = NO₂) were similarly prepared from the appropriate diphenyls. Ring closure of these compounds failed to take place on heating them with phosphorus oxychloride alone, but was readily accomplished by using phosphorus oxychloride in nitrobenzene solution (B.P. 520, 273; cf. Walls, *loc. cit.*) giving 9-(3'-pyridyl)- (II; R = R' = H) and 3-nitro-9-(3'-pyridyl)-phenanthridine (II; R = NO₂, R' = H) in excellent yields. When 4'-nitro-2-nicotinamidodiphenyl (I; R = H, R' = NO₂) was employed, however, ring closure appeared incomplete after 24 hours' heating, and the yield of 7-nitro-9-(3'-pyridyl)phenanthridine (II; R = H, R' = NO₂) was only 37%. This result is a further illustration of the polar influence of the 4'-nitro-grouping in depressing the mobility of the 2'-hydrogen atom involved in ring closure (cf. Morgan and Walls, *J.*, 1938, 390; Petrov, *loc. cit.*).

Conversion of (II; R = R' = H) into the mono-quaternary salt may clearly involve either the pyridyl or phenanthridyl basic centres. We have decided in favour of the former alternative on the following evidence. Reaction of 9-phenylphenanthridine, a compound structurally related to (II; R = R' = H) but possessing only the phenanthridyl basic centre, with methyl sulphate, led to the formation of 9-phenylphenanthridine 10-methylmethosulphate (IX; X = MeSO₃), converted by one molar equivalent of sodium hydroxide into the pseudo-base (X). Although this reaction may also yield the methohydroxide, it has been assumed by earlier

workers that the product obtained is actually the pseudo-base where experimental evidence favours such a conclusion; pseudo-bases differ from the corresponding quaternary hydroxides in that they are relatively insoluble in water and soluble in non-hydroxylic solvents (*e.g.*, light petroleum). The pseudo-base reverted on treatment with 1.15 molar equivalents of hydrochloric acid to the quaternary salt, converted by potassium iodide into the normal *methiodide*. These model transformations serve to characterise systems such as (IX). The reactions of the monoquaternary salts obtained from (II) with, in the first place, alkali, and secondly potassium ferricyanide-sodium hydroxide, however, followed a different pattern which could be interpreted only by assuming that it was the pyridyl nitrogen which was involved in salt formation. Thus both 9-(3'-pyridyl)phenanthridine 1'-methiodide (III; R = R' = H, X = I) and 3-nitro-9-(3'-pyridyl)phenanthridine 1'-methylmethosulphate (III; R = NO₂, R' = H, X = MeSO₄) failed to give sparingly soluble pseudo-bases when treated with one molar proportion of aqueous sodium hydroxide. (III; R = R' = H; X = I) was unchanged by heating with excess dilute sodium hydroxide for one minute. Treatment of a warm aqueous solution of (III; R = NO₂, R' = H, X = MeSO₄) with a large excess of sodium hydroxide precipitated a red amorphous material, probably the pseudo-base, which on vacuum sublimation gave a very small yield of 3-nitro-9-(6'-keto-1'-methyl-1': 6'-dihydro-3'-pyridyl)phenanthridine (IV; R = NO₂), also obtained in good yield from (III; R = NO₂, R' = H, X = MeSO₄) by hot alkaline ferricyanide oxidation, and characterised as its *hydrochloride*. Attempts to oxidise 9-(3'-pyridyl)phenanthridine 1'-methiodide (III; R = R' = H, X = I) with potassium ferricyanide-sodium hydroxide at room temperature led to the separation of the very sparingly soluble *ferricyanide*. When the reaction was carried out at 80° (cf. Diesbach and Aeschbach, *Helv. Chim. Acta*, 1945, **28**, 1392) in the presence of benzene, oxidation occurred to give 9-(6'-keto-1'-methyl-1': 6'-dihydro-3'-pyridyl)phenanthridine (IV; R = H), characterised by conversion into the *hydrochloride* and the *thiopyridone* derivative.

Conversion of (IV; R = H) into the quaternary salt led to the formation of 9-(6'-keto-1'-methyl-1': 6'-dihydro-3'-pyridyl)phenanthridine 10-methiodide (V; X = I), a compound which now exhibited the typical reactions of the 9-phenyl-10-methylphenanthridinium system (IX). Thus with 1.05 molar equivalent of sodium hydroxide it passed into the *pseudo-base* (VI), converted by 1.1 molar equivalent of hydrochloric acid into the methochloride, which was transformed into the methiodide (V; X = I) with potassium iodide. Attempts to oxidise (V; X = I) with aqueous alkaline ferricyanide at 80° in the presence of benzene were unsuccessful, only the pseudo-base (VI) being isolated.

The conversion of 9-(3'-pyridyl)phenanthridine 1': 10-dimethiodide (VII; R' = H, X = I) into (VI) would complete the series of reactions (II) to (VI) by two separate routes and supply further experimental evidence confirming these formulations. On treatment of (VII; R' = H, X = I) with 50% alcoholic alkaline ferricyanide, however, 10-methyl-9-phenanthridone (VIII) was obtained in place of the expected (VI), the quaternary pyridyl group having been removed. The same product was also formed by employing 9-phenylphenanthridine-10-methylmethosulphate (IX; X = MeSO₄) in place of (VII; R' = H, X = I). Attempts to oxidise (V; X = I) with 50% alcoholic alkaline ferricyanide, however, gave (VI) and not the phenanthridone (VIII). Further work showed that (VII; R' = H, X = I) could be converted into (VIII) by simply refluxing it with 50% alcoholic dilute sodium hydroxide. Treatment of (VII; R' = H, X = I) dissolved in a large excess of cold 2N-sodium hydroxide with potassium ferricyanide in very dilute solution, resulted in the loss of the quaternary group attached to the phenanthridyl nitrogen, the product isolated being (IV; R = H). Pictet and Patry (*Ber.*, 1893, **26**, 1966) have described the alkaline ferricyanide oxidation of phenanthridine 10-methiodide to 10-methyl-9-phenanthridone (VIII), and have also shown (*Ber.*, 1902, **35**, 2534) that steam distillation of phenanthridine 10-methoxyhydroxide yields 10-methyl-9:10-dihydrophenanthridine and (VIII). Morgan and Walls (*J.*, 1938, 391) have obtained (VIII) by heating 9-dimethylaminophenanthridine 10-methiodide with water. The formation of (VIII) from (VII; R' = H; X = I) and (IX; X = I) represents an extension of these observations, in that the elimination of a 9-aryl substituent is involved. This may take place by an oxidation of the tertiary C₉ alcohol (*e.g.*, X), or in the case of (VII; R' = H; X = I) which yields (VIII) by simple treatment with alkali, by direct transference of hydrogen from the C₉ hydroxyl group to the quaternary pyridyl group.

3- (III; R = NH₂, R' = H, X = Cl) and 7-Amino-9-(3'-pyridyl)phenanthridine 1'-methochloride (III; R = H, R' = NH₂, X = Cl) were best prepared from the corresponding *methiodides*. These were obtained by reducing the appropriate nitro-9-(3'-pyridyl)phenanthridine 1'-monomethylmethosulphate with reduced iron in acidified aqueous solution followed

by treatment of the reduction liquor with potassium iodide. Catalytic methods led to nuclear reduction.

3- (II; $R = NH_2$, $R' = H$) and 7-Amino-9-(3'-pyridyl)phenanthridine (II; $R = H$, $R' = NH_2$), obtained from the corresponding nitro-compounds by reduction with stannous chloride, were characterised by preparation of the acetyl derivatives. These gelatinous compounds were obtained crystalline only after sublimation in a high vacuum. 7-Amino-9-(3'-pyridyl)phenanthridine (II; $R = H$, $R' = NH_2$) was also obtained in 31% yield by catalytic reduction of the corresponding nitro-compound in glacial acetic acid with Adams's platinum oxide catalyst. When 2N-hydrochloric acid was substituted as solvent, however, simultaneous nuclear reduction invariably took place. As expected, attempts at the further reduction of the 7-amino-compound (II; $R = H$, $R' = NH_2$) in methanol or glacial acetic acid were unsuccessful, whereas nuclear reduction again occurred in 2N-hydrochloric acid.

The spasmolytic activities of (II; $R = R' = H$), (II; $R = NH_2$, $R' = H$), and (II; $R = H$, $R' = NH_2$) have been very kindly determined for us by Mr. R. Thorp (Wellcome Physiological Research Laboratories, Beckenham, Kent). The L.D.₅₀ of all three compounds, determined by intravenous injection in mice, was approximately 0.06 mg./g. Upon the isolated rabbit intestinal segment, a dilution of 1 : 100,000 of all three substances was about as effective as 1 : 50,000,000 of "trasentin" in relaxing the spasm caused by a 1 : 3,000,000 dilution of carbinoyl choline. Their spasmolytic activity was thus not of a high order.

The results of trypanocidal tests on (III; $R = NH_2$, $R' = H$, $X = Cl$) and (III; $R = H$, $R' = NH_2$, $X = Cl$) have already been reported (Wien, *Brit. J. Pharmacol.*, 1946, 1, 65). At the time these were carried out we had not reached a decision as to the structure of the mono-quaternary salts, to which Dr. Wien provisionally ascribed the phenanthridyl *N*-methochloride formulation.

EXPERIMENTAL.

Semimicro-analyses are by Mr. S. Bance, B.Sc., A.R.I.C., Research Laboratories, May and Baker, Ltd. Melting points are corrected.

2-Nicotinamidodiphenyl (I; $R = R' = H$).—Nicotinic acid (90 g.) was heated under reflux for 1 hour with thionyl chloride (250 c.c.), the mixture taken to dryness under reduced pressure on the water-bath, and the residue dissolved during 20 minutes in boiling chlorobenzene (1 l.). On addition of 2-aminodiphenyl (120 g.) in warm chlorobenzene (200 c.c.) a vigorous reaction occurred with evolution of hydrogen chloride and separation of a red oil which solidified. The solid product was collected, washed with ether, and crystallised from solution in methanol (1 l.) by addition of excess of aqueous ammonia. 2-Nicotinamidodiphenyl formed colourless octahedra from aqueous methanol (157 g.; 78%); m. p. 173—174° (Found: C, 78.8; H, 5.1; N, 10.4. $C_{18}H_{14}ON_2$ requires C, 78.8; H, 5.1; N, 10.2%).

5-Nitro-2-nicotinamidodiphenyl (I; $R = NO_2$, $R' = H$).—Nicotiny chloride hydrochloride (from 5 g. acid) dissolved in boiling chlorobenzene (35 c.c.), was treated with 5-nitro-2-aminodiphenyl (7 g.) for 5 minutes under reflux. After addition of pyridine (10 c.c.) and heating for 5 minutes, the mixture was cooled and the product precipitated with light petroleum (50 c.c.). The free base was obtained by crystallisation from alcohol (150 c.c.)—2N-ammonia (excess). 5-Nitro-2-nicotinamidodiphenyl formed long cream prisms from aqueous alcohol (8.6 g.; 83%); m. p. 160—161° (Found: C, 67.9; H, 4.2; N, 13.3. $C_{18}H_{13}O_2N_3$ requires C, 67.7; H, 4.0; N, 13.2%).

4'-Nitro-2-nicotinamidodiphenyl (I; $R = H$, $R' = NO_2$).—Nicotiny chloride hydrochloride (from 25 g. acid) in boiling chlorobenzene (200 c.c.) was treated with 4'-nitro-2-aminodiphenyl (35 g.) for 30 minutes under reflux. After addition of pyridine (30 c.c.) and a further 15 minutes heating, the product was precipitated with an equal volume of light petroleum (b. p. 100—120°). By solution in pyridine (400 c.c.; charcoal) and precipitation with excess of 2N-ammonia, 4'-nitro-2-nicotinamidodiphenyl was obtained, separating from pyridine—light petroleum (1 : 1) in small cream irregular prisms (40 g.; 77%); m. p. 226—227° (Found: C, 67.7; H, 4.0; N, 13.4. $C_{18}H_{13}O_2N_3$ requires C, 67.7; H, 4.0; N, 13.2%). Attempted preparations of this compound in pyridine at 100° instead of in boiling chlorobenzene yielded a product which could not readily be purified.

9-(3'-Pyridyl)phenanthridine (II; $R = R' = H$).—Phosphorus oxychloride (30 c.c.), 2-nicotinamidodiphenyl (20 g.), and nitrobenzene (200 c.c.) were heated under reflux for 20 hours. The mixture was basified with concentrated ammonia at 0° and the nitrobenzene removed in steam. The solids were collected and dissolved in concentrated hydrochloric acid (200 c.c.; charcoal), and the base was precipitated with ammonia at 0°. 9-(3'-Pyridyl)phenanthridine formed colourless needles from light petroleum (b. p. 80—100°) (13.5 g.; 72%); m. p. 125—127° (Found: C, 84.0; H, 4.7; N, 11.2. $C_{18}H_{13}N_3$ requires C, 84.4; H, 4.7; N, 10.9%). With methyl sulphate (0.95 mol.) in boiling benzene for $\frac{1}{2}$ hour it gave the 1'-methylmethosulphate, converted in aqueous solution into the 1'-methiodide (III; $R = R' = H$, $X = I$), yellow elongated plates from methanol of indefinite m. p. 259—269° (Found: N, 7.2; I, 32.0. $C_{18}H_{12}N_3CH_2I$ requires N, 7.0; I, 32.0%). The 1'-methoferricyanide, obtained by treating a warm aqueous solution of the 1'-methylmethosulphate with potassium ferricyanide, crystallised from aqueous methanol in irregular yellow plates, decomposing above 180° (Found: N, 16.2; Fe, 5.4. $(C_{18}H_{12}N_3)_3Fe(CN)_6$ requires N, 16.4; Fe, 5.4%). Reaction of (II; $R = R' = H$; 5.1 g.) with methyl sulphate (7.6 c.c.; 4 mols.) in dry nitrobenzene (400 c.c.) at 170—180° for 30 minutes gave the 1' : 10-dimethyldimethosulphate. Removal of nitrobenzene in steam, followed by addition of potassium iodide (20 g.) to the residual aqueous liquor (250 c.c.), gave the corresponding 1' : 10-dimethiodide (VII; $R' = H$, $X = I$). This salt formed golden irregular plates (8.8 g.; 82%)

from water; m. p. 237—242° with effervescence (preheated bath at 200°), resolidifying and melting again at 270—275° (Found: N, 5.2; I, 46.8. $C_{18}H_{13}N_3 \cdot 2CH_3I$ requires N, 5.2; I, 47.0%).

3-Nitro-9-(3'-pyridyl)phenanthridine (II; R = NO_2 , R' = H).—Phosphorus oxychloride (200 c.c.), 5-nitro-2-nicotinamidodiphenyl (90 g.), and nitrobenzene (1.6 l.) were refluxed for 20 hours. The brown product which separated on cooling was boiled with pyridine (1 l.)—2N-ammonia (600 c.c.). **3-Nitro-9-(3'-pyridyl)phenanthridine** separated from pyridine in faintly yellow felted needles (80 g.; 94%); m. p. 250—252° (Found: C, 71.9; H, 3.8; N, 14.0. $C_{18}H_{11}O_3N_3$ requires C, 71.7; H, 3.7; N, 13.9%). The base (15 g.) was treated in nitrobenzene (400 c.c.) with methyl sulphate (4.5 c.c.; 0.95 mol.) at 170°, followed by precipitation with ether (300 c.c.). The **1'-methylmethosulphate** (86% yield) formed bulky colourless needles from methanol-ether; m. p. 210—212° (preheated bath) [Found N, 9.7; S, 7.5. $C_{18}H_{11}O_3N_3 \cdot (CH_3)_2SO_4$ requires N, 9.9; S, 7.5%].

7-Nitro-9-(3'-pyridyl)phenanthridine (II; R = H, R' = NO_2), prepared (37% yield) in a similar manner to (II; R = NO_2 , R' = H) separated in felted buff needles from pyridine; m. p. 292—293° (Found: C, 71.8; H, 3.7; N, 14.0. $C_{18}H_{11}O_3N_3$ requires C, 71.7; H, 3.7; N, 13.9%). Reaction of (II; R = H, R' = NO_2) in nitrobenzene at 170° with methyl sulphate (0.9 mol.) gave the **1'-methylmethosulphate** (III; R = H, R' = NO_2 , X = $MeSO_4$), small irregular plates from methanol-ether (78% yield); m. p. 251—253° (with previous softening) [Found: N, 9.8; S, 7.6. $C_{18}H_{11}O_3N_3 \cdot (CH_3)_2SO_4$ requires N, 9.9; S, 7.5%]. When the methyl sulphate was increased to 3 mols. the **1':10-dimethyl-dimethosulphate** (VII; R' = NO_2 , X = $MeSO_4$) was obtained, small cream plates from methanol-ether; m. p. 256—258° (with previous softening) [Found: N, 7.5; S, 11.7. $C_{18}H_{11}O_3N_3 \cdot 2(CH_3)_2SO_4$ requires N, 7.6; S, 11.6%]. The **1'-methopicate** formed bright yellow irregular needles from acetone; m. p. 300—302° (Found: N, 15.4. $C_{18}H_{11}O_3N_3 \cdot C_7H_5O_2N_2$ requires N, 15.6%).

Model Experiments with Quaternary Salts of 9-Phenylphenanthridine.—Reaction of 9-phenylphenanthridine (Morgan and Walls, J., 1931, 2451) in benzene with methyl sulphate (2 mols.) gave the **10-methylmethosulphate** (IX; X = $MeSO_4$), which separated from alcohol-ether in colourless prisms, m. p. 222—224° [Found: N, 4.0; S, 8.4. $C_{19}H_{13}N_3 \cdot (CH_3)_2SO_4$ requires N, 3.7; S, 8.4%]. The **10-methiodide** (IX; X = I) crystallised from water as well-defined bright yellow prisms which decomposed sharply at temperatures between 235 and 260°, depending on the rate of heating (Found: N, 3.7; I, 32.1. $C_{19}H_{13}N_3 \cdot CH_3I$ requires N, 3.6; I, 32.0%). The *pseudo-base* (X), precipitated from an aqueous solution of the 10-methylmethosulphate (IX; X = $MeSO_4$) by 1 mol. of N-sodium hydroxide, was extracted with ethyl acetate. It crystallised from light petroleum (b. p. 80—100°) in colourless prisms, m. p. 132—136° (Found: C, 83.8; H, 6.0; N, 5.0. $C_{20}H_{17}ON$ requires C, 83.6; H, 5.9; N, 4.9%). The *pseudo-base* (0.025 g.) dissolved in water (2 c.c.) containing N/10-hydrochloric acid (1 c.c.; 1.15 mol.), was treated with potassium iodide (0.3 g.), giving 9-phenylphenanthridine 10-methiodide (IX; X = I) identical with an authentic specimen.

9-(6'-Keto-1'-methyl-1':6'-dihydro-3'-pyridyl)phenanthridine (IV; R = H).—The yellow suspension obtained by treating a warm solution of 9-(3'-pyridyl)phenanthridine 1'-methiodide (8 g.) in water (400 c.c.) with potassium ferricyanide (20 g. in 50 c.c. water) was made alkaline by addition of 2N-sodium hydroxide (50 c.c.) and then vigorously stirred on the steam-bath for 40 minutes. Benzene (1 l.) was added to take up the product as it was formed. The red benzene layer was separated, washed with water (50 c.c.), and concentrated to 100 c.c. under reduced pressure. Addition of light petroleum precipitated **9-(6'-keto-1'-methyl-1':6'-dihydro-3'-pyridyl)phenanthridine** (4.1 g.; 70%), small buff prisms from chloroform-acetone; m. p. 211—212° (Found: C, 79.7; H, 5.0; N, 9.8. $C_{18}H_{11}ON_3$ requires C, 79.7; H, 4.9; N, 9.8%). A 57% yield of (IV; R = H) was also obtained by adding 2N-sodium hydroxide (2 c.c.) in one portion to a solution of 9-(3'-pyridyl)phenanthridine 1'-methiodide (0.4 g.) and potassium ferricyanide (1.6 g.) in 50% ethanol (40 c.c.), and refluxing the mixture for 30 minutes. The product was isolated by removing the ethanol under reduced pressure and extracting the residual suspension with benzene. Although (IV; R = H) was largely insoluble in boiling 2N-hydrochloric acid (0.13 g. in 4 c.c.), the *hydrochloride* was obtained by diluting a solution in warm concentrated hydrochloric acid (0.3 g. in 3 c.c.) with water (25 c.c.). Fawn hydrated needles separated which decomposed evolving hydrochloric acid gas above 205° (Found: C, 66.6; H, 5.3; N, 8.3; Cl, 10.3. $C_{18}H_{11}ON_3 \cdot HCl \cdot H_2O$ requires C, 66.9; H, 5.0; N, 8.2; Cl, 10.4%). The *thiopyridone* derivative was obtained by refluxing the pyridone (IV; R = H; 0.57 g.) in chlorobenzene (20 c.c.) with finely powdered phosphorus pentasulphide (1.4 g.) for 1 hour. The hot reaction mixture was filtered and the insoluble material triturated with 2N-sodium hydroxide (40 c.c.). The brown insoluble residue (0.3 g.) was collected. It crystallised from alcohol (15 c.c.) in fawn prisms (0.1 g.), m. p. 182—197° (Found: N, 9.4; S, 10.8. $C_{18}H_{11}N_3S$ requires N, 9.3; S, 10.6%).

3-Nitro-9-(6'-keto-1'-methyl-1':6'-dihydro-3'-pyridyl)phenanthridine (IV; R = NO_2).—2N-Sodium hydroxide (20 c.c.) was added to the yellow suspension obtained when 3-nitro-9-(3'-pyridyl)phenanthridine 1'-methylmethosulphate (1 g.) in water (250 c.c.) at 60° was treated with potassium ferricyanide (3 g.). The mixture was then rapidly heated to boiling. After 15 minutes the suspension was cooled. The solid product, washed free from alkali, crystallised from pyridine (25 c.c.)—methanol (50 c.c.) as well-defined light brown needles (0.5 g.; 65%); m. p. 304—305° (Found: C, 68.8; H, 4.2; N, 12.8. $C_{19}H_{13}O_3N_3$ requires C, 68.9; H, 4.0; N, 12.7%). Sublimation of the red amorphous precipitate (2.2 g.) obtained by precipitating a warm aqueous solution (40 c.c.) of 3-nitro-9-(3'-pyridyl)phenanthridine 1'-methylmethosulphate (3.2 g.) with sodium hydroxide (15 c.c. of 50% w/v. solution), at 280°/0.02 mm. yielded a yellow crystalline sublimate (0.1 g.). After crystallisation from pyridine—light petroleum, (IV; R = NO_2) was obtained, m. p. 304—305°, not depressed in admixture with an authentic sample (Found: C, 68.9; H, 4.3; N, 12.6%). Although (IV; R = NO_2) was insoluble in boiling N-hydrochloric acid (0.1 g. in 4 c.c.), the *hydrochloride* was prepared by diluting a solution in hot concentrated hydrochloric acid. The salt separated in well-defined brown prisms which evolved hydrogen chloride above 140° and melted at 303—305° (Found: N, 11.2; Cl, 9.8. $C_{19}H_{13}O_3N_3 \cdot HCl$ requires N, 11.4; Cl, 9.7%). A mixed melting point of this hydrochloride and the corresponding base showed no depression.

9-(6'-Keto-1'-methyl-1':6'-dihydro-3'-pyridyl)phenanthridine 10-Methiodide (V; X = I).—9-(6'-Keto-1'-methyl-1':6'-dihydro-3'-pyridyl)phenanthridine (4.2 g.) was treated in xylene (150 c.c.) with

methyl sulphate (6 c.c.; 4 mols.) for 30 minutes. The gum which separated on cooling was dissolved in hot water (100 c.c.). Addition of potassium iodide (9 g.) gave the *methiodide*, golden prisms from water (2.9 g.); m. p. 240–243° (decomp.) (Found: N, 6.6; I, 29.7. $C_{18}H_{13}ON_3CH_3I$ requires N, 6.5; I, 29.7%). The *methiodide* (0.4 g.) in ethanol (5 c.c.) was treated with *N*-sodium hydroxide (1 c.c.; 1.05 mol.). On dilution with water the *pseudo-base* (VI) was precipitated, forming irregular colourless prisms from aqueous alcohol (0.24 g.; 80%); m. p. 194–196° (Found: C, 75.3; H, 5.96; N, 8.9. $C_{20}H_{15}O_2N_3$ requires C, 75.5; H, 5.7; N, 8.8%). The *pseudo-base* (0.029 g.) dissolved in water (6 c.c.) containing *N*/10-hydrochloric acid (1 c.c.; 1.1 mol.) was treated with potassium iodide (0.3 g.), giving 9-(6'-keto-1'-methyl-1': 6'-dihydro-3'-pyridyl)phenanthridine 10-methiodide (V; X = I) identical with an authentic specimen.

Attempted Oxidations of 9-(3'-Pyridyl)phenanthridine 1': 10-Dimethiodide (VII; R' = H, X = I).—(a) 2*N*-Sodium hydroxide (2 c.c.) was added to a boiling solution of 9-(3'-pyridyl)phenanthridine 1': 10-dimethiodide (0.54 g.) and potassium ferricyanide (1.6 g.) in 50% ethanol (40 c.c.). After 30 minutes the alcohol was removed and the insoluble precipitate crystallised from light petroleum (b. p. 80–100°); colourless needles of 10-methyl-9-phenanthridone (VIII) separated (0.12 g.; 57%); m. p. 108–110° (Pictet and Patry, *Ber.*, 1893, **26**, 1966, give m. p. 108°) (Found: N, 6.8. Calc. for $C_{18}H_{11}ON$: N, 6.7%). If the potassium ferricyanide were omitted in the above preparation the yield of (VIII) fell to 24%. When 9-phenylphenanthridine 10-methylmethosulphate was substituted for (VII; R' = H; X = I) in the above alcoholic alkaline ferricyanide oxidation a 23% yield of (VIII) was obtained (Found: C, 80.5; H, 5.5%). The identity of this product was confirmed by a mixed melting point determination.

(b) Potassium ferricyanide (5.4 g.) was dissolved in a cold solution of the dimethiodide (VII; R' = H, X = I) in 2*N*-sodium hydroxide (40 c.c.) diluted to 1 l. with water. After two days the collected precipitated solids were extracted with ethanol (10 c.c.). The white solid which separated from the filtered extract crystallised from benzene-light petroleum as almost white prisms (0.13 g.; 45%), m. p. 206–210°, identical with 9-(6'-keto-1'-methyl-1': 6'-dihydro-3'-pyridyl)phenanthridine (IV; R = H).

(c) A cold solution of the dimethiodide (VII; R' = H, X = I) in water (500 c.c.) containing potassium ferricyanide (1.0 g.) was treated with *N*-sodium hydroxide (3 c.c.; 3 mol.). 1 c.c. of *N*-sodium hydroxide was added daily for 7 days by which time a stringy white precipitate had separated. This material (0.05 g.) was crystallised from aqueous alcohol and light petroleum giving 10-methyl-9-phenanthridone (VIII), m. p. 109–111°, mixed melting point with an authentic specimen 108–111°.

3-Amino-9-(3'-pyridyl)phenanthridine (II; R = NH₂, R' = H).—3-Nitro-9-(3'-pyridyl)phenanthridine (4 g.) in concentrated hydrochloric acid (100 c.c.) was treated at the boiling point with stannous chloride (9 g.) in concentrated hydrochloric acid (25 c.c.), refluxing being maintained for a further 45 minutes. After being allowed to cool, the yellow stannichloride was collected and dissolved in water (40 c.c.), the base was liberated with 50% sodium hydroxide and extracted with chloroform (250 c.c.). After solution in 2*N*-hydrochloric acid (charcoal) and reprecipitation, it distilled at 230°/0.05 mm. and was crystallised from methanol (40 c.c.) and water (10 c.c.). *3-Amino-9-(3'-pyridyl)phenanthridine monohydrate* formed pale yellow felted needles, m. p. 127–128° (decomp.) (Found: N, 14.7. $C_{18}H_{13}N_3 \cdot H_2O$ requires N, 14.5%). The anhydrous base formed light brown rectangular rods from benzene (1.2 g.; 33%); m. p. 165–166° (Found: C, 79.5; H, 4.6; N, 15.3. $C_{18}H_{13}N_3$ requires C, 79.7; H, 4.8; N, 15.5%). The *acetyl* derivative was prepared by heating the base (0.5 g.) and a little anhydrous sodium acetate in glacial acetic acid (5 c.c.) and acetic anhydride (5 c.c.) for 1½ hours. After sublimation at 260°/10 mm. it formed flat needles (0.3 g.); m. p. 253° (Found: C, 77.1; H, 4.9; N, 13.4. $C_{20}H_{15}ON_3$ requires C, 76.7; H, 4.8; N, 13.4%).

3-Amino-9-(3'-pyridyl)phenanthridine 1'-Methochloride (III; R = NH₂, R' = H, X = Cl).—Reduced iron (5 g.) was added as rapidly as possible to a boiling aqueous solution (40 c.c.) of 3-nitro-9-(3'-pyridyl)phenanthridine 1'-methylmethosulphate (4.27 g.), previously acidified (Congo-red) with 2*N*-sulphuric acid. After 30 minutes the mixture was filtered (charcoal) and treated with potassium iodide (5 g.). After 12 hours at 0° the solids were collected and crystallised from water (50 c.c.) and then from methanol. *3-Amino-9-(3'-pyridyl)phenanthridine 1'-methiodide* (III; R = NH₂, R' = H, X = I) formed light brown irregular plates of indefinite m. p. 180–240° (Found: C, 55.1; H, 4.3; N, 10.4; I, 30.8. $C_{18}H_{13}N_3CH_3I$ requires C, 55.2; H, 3.9; N, 10.2; I, 30.8%). The *methochloride* (III; R = NH₂; R' = H; X = Cl) formed brown rods from ethereal methanol, m. p. 256–257° (Found: N, 13.1; Cl, 11.3. $C_{18}H_{13}N_3CH_2Cl$ requires N, 13.1; Cl, 11.1%). It gave positive primary amine tests.

7-Amino-9-(3'-pyridyl)phenanthridine (II; R = H, R' = NH₂) formed a bright red stannichloride. The base separated from chlorobenzene in yellow rods (64% yield), m. p. 227–229° (Found: C, 79.5; H, 4.6; N, 15.2. $C_{18}H_{13}N_3$ requires C, 79.7; H, 4.8; N, 15.5%). The *acetyl* derivative, after sublimation at 290–300°/0.01 mm., formed felted colourless needles, m. p. 296–298° (Found: C, 76.5; H, 5.0; N, 13.4. $C_{20}H_{15}ON_3$ requires C, 76.7; H, 4.8; N, 13.4%).

7-Amino-9-(3'-pyridyl)phenanthridine 1'-Methochloride (III; R = H, R' = NH₂, X = Cl).—The *methiodide* (III; R = H, R' = NH₂, X = I) separated from water in light brown needles, m. p. 243–244° (decomp.) (Found: C, 55.4; H, 3.9; N, 10.3; I, 30.8. $C_{18}H_{13}N_3CH_3I$ requires C, 55.2; H, 3.9; N, 10.2; I, 30.8%). The *methochloride* crystallised from ethereal methanol in orange plates, m. p. 265–267° (Found: N, 12.8; Cl, 11.2. $C_{18}H_{13}N_3CH_2Cl$ requires N, 13.1; Cl, 11.1%); it gave positive tests for a primary amine.

We thank the Directors of May and Baker, Ltd., for facilities generously placed at the disposal of one of us (W. R. W.).

268. A Re-examination of the Reported *m*-Nitration of Phenols and Phenolic Ethers.

By C. A. BUNTON, G. J. MINKOFF, and R. I. REED.

The products of mononitration of phenol and anisole have been analysed by several independent methods for the presence of *m*-isomerides. The conclusion has been reached that, contrary to the views of earlier investigators, the proportions in which *m*-isomerides are formed in these reactions are less than 0.1%.

ARNALL claimed (*J.*, 1924, 125, 911) that 2.1—3.3% of *m*-nitrophenol is formed when phenol is mononitrated, as it can be, smoothly, by nitric acid in acetic acid. This conclusion is supported by the claim of Griffiths, Walkey, and Watson (*J.*, 1934, 631) that 1.4—2.2% of *m*-nitroanisole is formed in the mononitration of anisole by nitric acid of *d* 1.42, by nitric acid in sulphuric acid, nitric acid in acetic acid, nitric acid in acetic anhydride, and by benzoyl nitrate.

It seems improbable that strongly *op*-orienting groups like -OH and -OR could lead to appreciable *m*-nitration, when the weakly *op*-orienting halogens do not do so. This conclusion is reinforced by the consideration that the *op*-orienting property of -OR groups, as of halogens, in aromatic substitution, is a tautomeric effect, and, unlike the inductive effect, is almost wholly a polarisability, therefore leading exclusively to *op*-substitution (Ingold and Shaw, *J.*, 1927, 2918).

Being engaged in a kinetic study of some of the special features of the mono-nitration of phenol and its derivatives we investigated these outstanding points concerning the orientation of nitration in these compounds.

Arnall and Griffiths, Walkey, and Watson based their conclusions on thermal analyses of the isolated nitration products; such methods may be unreliable unless by-products of mononitration can be removed more completely than can sometimes be established by ordinary analysis, however satisfactory apparently.

We have used three methods, applying one to phenol, one to anisole, and a third to both. These three methods give consistent results, disagreeing with those of the previous workers.

The first method, that of chromatographic adsorption, was applied to the product of the mononitration of phenol by nitric acid in acetic acid. It is possible to resolve mixtures of *o*-, *m*-, and *p*-nitrophenol by this method (cf. Strain, "Chromatographic Adsorption Analysis", Interscience Publishers, Inc., New York, 1942, p. 94); but, in application to the mononitration product of phenol, it was found that repeated adsorption of the various bands failed to reveal any trace of *m*-nitrophenol. This result, by itself, is not conclusive, as the method is difficult to standardise for small quantities of the *m*-compound, especially as the chromatogram is complicated by the presence of small amounts of derivatives of dihydroxydiphenylnitrogen oxide, which are formed during nitration of phenols.

The other method applied to phenol was an extension of Albert and Large's specific test for *m*-diamines (*Nature*, 1938, 142, 435; Albert, *J.*, 1939, 920). They observed that *m*-diamines react with glycerol and oxalic acid in the presence of zinc or calcium chloride to give the fluorescent 2 : 8-diaminoacridine. By addition of stannous chloride to their reagent they extended the test to *m*-nitroamines and *m*-dinitro-compounds.

Our further extension of this test was to convert *m*-nitrophenol into *m*-nitroaniline by heating with aminozinc chloride and ammonium chloride. As the fluorescence of 2 : 8-diaminoacridine is quenched by phenols, any unconverted phenols were removed by extraction of the product from alkaline solution. No fluorescence was observed when this test was applied to the products of nitration of phenol by nitric acid in acetic acid, although when a trace of *m*-nitrophenol was first added to the nitration product a strong fluorescence was observed. Control experiments by this method established that the proportion of *m*-nitration under our conditions was less than 0.1%.

The first method to be applied to the nitration product of anisole was that of thermal analysis; but the fractionating column used in the removal of the non-isomeric by-products of mononitration was probably much more efficient than any at the disposal of earlier workers. We investigated this mononitration under several of the conditions used by Griffiths, Walkey, and Watson, *viz.*, nitration by nitric acid of *d* 1.42, by nitric acid in sulphuric acid, and by nitric acid in acetic acid. Two methods of thermal analysis were applied to each isolated product. One was a determination of the eutectic temperature, as the second arrest-point of the cooling curve. This temperature was always that of the binary mixture of *o*- and *p*-nitroanisoles to within our experimental error (about $\pm 0.1^\circ$). The other method involved

a determination of the clearing point, followed by similar determinations after additions of pure *o*-nitroanisole sufficient, first, to lower the clearing temperature in stages to the eutectic point, and then to raise it beyond that point. In each case, the composition-temperature curve thus traced coincided (to within the accuracy of the clearing point measurements: usually $\pm 0.3^\circ$), with the curve for binary mixtures of *o*- and *p*-nitroanisoles. This curve was first traced by Griffiths, Walkey, and Watson (*loc. cit.*), whose measurements we confirm. These determinations showed that the proportions of *m*-isomeride in our mononitration products could not have been more than a small fraction of 1%.

The second method applied to the mononitration products of anisole was the fluorescence test as described for the nitrophenols. Like *m*-nitrophenol, *m*-nitroanisole is converted into *m*-nitroaniline by heating with aminozinc chloride and ammonium chloride, and the product can be converted into 2:8-diaminoacridine by the method of Albert and Large. This test gave no detectable fluorescence when applied to the nitration products of anisole, although, as with phenol, a readily detectable fluorescence was obtained on the addition of small amounts of *m*-nitroanisole to the nitration product. Control experiments on these lines give an upper limit of 0.1% of *m*-nitration in the mononitration of anisole.

Thus it is proved by three independent methods that the proportions of *m*-isomeride formed in the mononitration of phenol and anisole are lower than we could detect, and very much lower than the proportions previously reported.

EXPERIMENTAL.

Materials.—Phenol was dried and distilled under reduced pressure in an all-glass apparatus. Anisole, alkali-washed and distilled, had b. p. $154-154.5^\circ$. The nitrophenols, from British Drug Houses, Ltd., were not further purified. The *m*- and *p*-nitroanisole, after crystallisation from aqueous alcohol, and the *o*-nitroanisole, prepared from steam-distilled *o*-nitrophenol and distilled, had m.p.s agreeing with those of Griffiths, Walkey, and Watson (here given in parentheses); *o*-, 10.4° (10.45°); *m*-, 35.7° (35.5°); *p*-, 52.1° (52.0°). Acetic acid was purified with chromium trioxide and fractionated. Nitric acid (95%) was distilled successively from 100% sulphuric acid and barium nitrate.

Miscellaneous Methods.—The initial content of the lower oxides of nitrogen in the nitrating mixtures was determined by the chloramine-r method (von Eck, *Pharm. Weekblad*, 1926, **63**, 1117; see also Minkoff, Thesis, London, 1945). The nitration of phenol by nitric acid in acetic acid was carried out with excess of phenol at 20° . The nitration products were poured into excess of alkali, and unchanged phenol was removed by treatment with carbon dioxide and ether. The mixture was just acidified with acetic acid, extracted with ether, and washed. The ether was removed, and the product dried in a vacuum desiccator. The nitrations of anisole by nitric acid (*d* 1.42), by nitric acid in sulphuric acid, and by nitric acid in acetic acid, were carried out essentially as described by Griffiths, Walkey, and Watson (*loc. cit.*). The products were extracted by ether from excess of alkali. Activated alumina was used for chromatographic adsorption; mixtures of ether and benzene were used as solvent, and in order to develop the chromatogram. Nitrophenols and nitroanisoles, either reference specimens or nitration products, were converted into nitroanilines by heating with aminozinc chloride (4 parts) and ammonium chloride (1 part) at 330° for 30 hours (cf. Menz and Muller, *Ber.*, 1886, **19**, 2916). The nitroanilines were then treated by the method of Albert and Large (*loc. cit.*). Cooling curves were determined in double-walled tubes, with stirring. Clearing points were determined in narrow, thin-walled tubes with stirring by a fine glass rod.

Examples of Thermal Analyses for the Nitration of Anisole.—(a) Anisole (0.95 g.-mol.) was treated with nitric acid (*d* 1.42; 1 g.-mol.) at 45° for 5 hours with continuous stirring. The product yielded the following data: Eutectic temperature from cooling curve, -7.0° . Clearing point, $+23.3^\circ$. Deduced composition *o*/(*o* + *p*) = 43.1% (Found: C, 55.9; H, 4.7; N, 9.1. Calc. for $C_7H_7O_3N$: C, 55.0; H, 4.8; N, 9.1%). Purity by $TiCl_3$ equivalent, 99.8%). Mixtures of the product with *o*-nitroanisole gave the following results:

Calc. % <i>o</i> - after addn.	43.1	65.0	69.8	80.0	84.5
Clearing point, calc.	($+23.3^\circ$)	$+0.6^\circ$	-6.3°	-0.6°	$+2.6^\circ$
" " obs.	$+23.3^\circ$	$+0.9^\circ$	-6.1°	-0.4°	$+2.3^\circ$

(b) Anisole (0.45 g.-mol.) was treated with a mixture of nitric acid (*d* 1.42; 0.5 g.-mol.) and sulphuric acid (0.5 g.-mol.) at 45° for 4 hours with continuous stirring. The product yielded the following data: Eutectic temperature from cooling curve, -7.3° . Clearing point, $+26.2^\circ$. Deduced composition, *o*/(*o* + *p*) = 39.8% (Found: C, 55.4; H, 4.5; N, 9.9%. Purity by $TiCl_3$ equivalent, 99.9%).

Calc. % <i>o</i> - after addn.	39.8	66.6	68.1	72.8	77.1

" " obs.	$+26.2^\circ$	-1.9°	-4.3°	-5.5°	-2.1°

(c) Anisole (0.05 g.-mol.) was treated with 200 c.c. of nitric acid (3M) in acetic acid at 20° for 12 hours, the initial concentration of nitrous acid being 0.03M. The product yielded the following data: Eutectic temperature from cooling curve, -7.2° . Clearing point, $+33.0^\circ$. Deduced composition, *o*/(*o* + *p*) = 30.5% (Found: C, 56.0; H, 4.8; N, 9.0%. Purity by $TiCl_3$ equivalent, 100.1%).

Calc. % <i>o</i> - after addn.	30.5	47.4	64.6	71.3	75.1	84.5
Clearing point, calc.	($+33.0^\circ$)	$+20.2^\circ$	$+1.5^\circ$	-6.4°	-3.8°	$+2.0^\circ$
" " obs.	$+33.0^\circ$	$+20.4^\circ$	$+2.0^\circ$	-6.1°	-3.7°	$+2.5^\circ$

(d) Anisole (0.05 g.-mol.) was treated with 200 c.c. of nitric acid (6.3M) in acetic acid at 20° for 15 hours, the initial concentration of nitrous acid being 0.12M. The product yielded the following data: Eutectic temperature from cooling curve, -7.0°. Clearing point, +30.4°. Deduced composition, $o/(o + p) = 34.0\%$ (Found: C, 55.1; H, 4.7; N, 10.0%. Purity by TiCl_3 equivalent, 99.8%).

Calc. % <i>o</i> - after addn.	34.0	44.4	59.6	74.0	87.5
Clearing point, calc.	(+30.4°)	+22.7°	+7.6°	-4.5°	+3.8°
" " obs.	+30.4°	+23.0°	+7.5°	-4.4°	+3.6°

Synthetic mixtures. (i) A mixture of *o*- and *p*-nitroanisole of composition $o/(o + p) = 69.3\%$ gave the following results: Eutectic temperature, -7.2° (Griffiths *et al.* give the same value). Clearing point, -5.8° (interpolated from accepted values, -5.7°). Clearing point after addition of 2.0% of *m*-nitroanisole, -6.7°.

(ii) A mixture of *o*- and *p*-nitroanisole of composition $o/(o + p) = 81.8\%$ gave the following results: Clearing point, +0.9° (interpolated from accepted values, +0.7°). Clearing point after addition of 1.5% of *m*-nitroanisole, +0.6°.

Microanalyses were carried out by Drs. G. Weiler and F. B. Strauss of Oxford.

The authors wish to thank Professor E. D. Hughes and Professor C. K. Ingold for their encouragement and interest in this work.

NOTES.

1:9-Diaminoacridine. By (Miss) E. K. KLEIN and F. N. LAHEY.

WITH the appearance of a paper by Albert, Rubbo, Goldacre, Davey, and Stone (*Brit. J. Exp. Path.*, 1945, 26, 160) and one by Craig (*J.*, 1946, 534), in which reference was made to 1:9-diaminoacridine supplied by one of us, it becomes desirable to record the synthesis of this substance, although the work for which it was prepared has not yet been successfully concluded.

The synthesis was accomplished along standard lines. Condensation of 2-bromo-3-nitrobenzoic acid with *o*-nitroaniline in the presence of sodium carbonate without the use of a solvent gave 2:2'-dinitrodiphenylamine-6-carboxylic acid. The same product was obtained from 3-nitroanthranilic acid, *o*-bromonitrobenzene, and sodium carbonate with nitrobenzene as a solvent. Ring closure of 2:2'-dinitrodiphenylamine-6-carboxylic acid was accomplished with either sulphuric acid or phosphorus oxychloride yielding 1:9-dinitroacridone, which was readily reduced to 1:9-diaminoacridone by stannous chloride and hydrochloric acid or by sodium hydrosulphite. Reduction of 1:9-diaminoacridone with sodium amalgam gave 1:9-diaminoacridine directly, apparently without the intermediate formation of the acridin.

1:9-Diaminoacridine crystallises in yellow needles, m. p. 177°. It gives a colourless hydrochloride and is further characterised by the formation of an acetyl derivative, m. p. 250–251°.

2:2'-Dinitrodiphenylamine-6-carboxylic Acid.—(a) 2-Bromo-3-nitrobenzoic acid (5.0 g.), *o*-nitroaniline (5.0 g.), sodium carbonate (2.0 g.), and a trace of copper powder were thoroughly mixed and heated at 190–210° for 2 hours with stirring. On cooling, benzene was added, and the sodium salts were filtered off and taken up in hot water. On cooling this solution in ice, the sodium salt of 2:2'-dinitrodiphenylamine-6-carboxylic acid separated, and was filtered off and acidified with hydrochloric acid. 2:2'-Dinitrodiphenylamine-6-carboxylic acid crystallised from ethyl alcohol or xylene in yellow crystals, m. p. 246°. Yield, 1.2 g. (Found: N, 13.84. $\text{C}_{13}\text{H}_9\text{O}_6\text{N}_3$ requires N, 13.86%).

(b) A mixture of sodium 3-nitroanthranilate (4.1 g.), *o*-bromonitrobenzene (6.0 g.), sodium carbonate (1.06 g.), a trace of copper powder, and nitrobenzene (30 ml.) was refluxed for 4 hours. It was then poured into benzene and the precipitated sodium salts filtered off. The acid obtained on acidification was recrystallised from ethyl alcohol, and was identical with that recorded above. Yield, 1.6 g.

1:9-Dinitroacridone.—2:2'-Dinitrodiphenylamine-6-carboxylic acid (1.0 g.) and concentrated sulphuric acid (7 ml.) were heated on a steam-bath with stirring for 15 minutes. The dark green solution was then poured on ice. The precipitated 1:9-dinitroacridone was filtered off and heated with sodium carbonate solution and then with water. It crystallised from xylene in fluffy orange crystals, m. p. 257–258°. Yield, 0.7 g. (Found: C, 54.9; H, 2.6. $\text{C}_{13}\text{H}_7\text{O}_4\text{N}_3$ requires C, 54.7; H, 2.5%). The same compound was obtained by using phosphorus oxychloride for ring closure.

2:2'-Dinitrodiphenylamine-6-carboxylic acid (1.0 g.) was refluxed with phosphorus oxychloride (10 ml.) for 1 hour. The excess of phosphorus oxychloride was removed under reduced pressure and the dark residue treated with water and filtered off. The brown solid was boiled for 15 minutes with 5% hydrochloric acid and again filtered. It was then dissolved in boiling *N*/5-potassium hydroxide (50% alcohol). From this solution, 1:9-dinitroacridone was precipitated with dilute hydrochloric acid. Yield, 0.7 g.

1:9-Diaminoacridone.—Stannous chloride (2.5 g.) was dissolved in boiling concentrated hydrochloric acid (9 ml.) and the solution saturated with hydrogen chloride. 1:9-Dinitroacridone (1 g.) was added during 1 hour with stirring, and the boiling continued for half an hour after the addition was complete. The stannic chloride complex (1.8 g.) which settled out was filtered off, washed with ether and dissolved in 50 ml. of hot water. The solution was cooled in ice and a slight excess of ammonia (*d* 0.88) added.

The yellow precipitate was dried and extracted repeatedly with boiling absolute alcohol. Evaporation of the alcohol gave 1:9-diaminoacridone as greenish-yellow needles which did not melt up to 320°. Yield, 0.4 g. (Found: C, 68.7; H, 4.6. $C_{13}H_{11}ON_2$ requires C, 69.3; H, 4.9%).

An easier method of reduction involved the use of sodium hydrosulphite. 1:9-Diaminoacridone (1.0 g.) was suspended in hot aqueous ethyl alcohol and sodium hydrosulphite added with constant stirring until a clear red solution was produced. A little hydrochloric acid was added and the solution boiled for $\frac{1}{2}$ hour. Ammonia precipitated the 1:9-diaminoacridone. Yield, 0.5 g.

1:9-Diaminoacridine.—1:9-Diaminoacridone (0.3 g.) was suspended in 30 ml. of water at 80°. Sodium amalgam (5%; 12.0 g.) was added gradually over 2 hours with stirring, and heating continued for another 2 hours. After cooling, the precipitate was filtered off, washed with water, and crystallised from 30% alcohol. Yield, 0.22 g. 1:9-Diaminoacridine formed golden-yellow crystals, m. p. 177° (Found: C, 74.5; H, 5.3. $C_{13}H_{11}N_2$ requires C, 74.6; H, 5.3%). It gave a colourless solution in hydrochloric acid. Treatment with acetic anhydride and working up in the usual way gave a diacetyl derivative, m. p. 250–251° (Found: N, 14.5. $C_{17}H_{15}O_2N_2$ requires N, 14.2%).—UNIVERSITY OF MELBOURNE. [Received, November 28th, 1946.]

The Preparation and Bacteriostatic Action of Some Aminochalkones and Related Compounds.

By D. H. MARRIAN, P. B. RUSSELL, and A. R. TODD.

KUHN, MÖLLER, WENDT, and BEINERT (*Ber.*, 1942, **75**, 711) prepared a number of analogues of the sulphonamide drugs in which a *p*-aminobenzoyl group was substituted for the *p*-aminobenzenesulphonyl residue and showed that they possessed much weaker bacteriostatic properties than sulphanilamide. Later, however, Kuhn, Möller, and Wendt (*Ber.*, 1943, **76**, 405) showed that 4:4'-diaminobenzil has from two to six times the activity of sulphanilamide against *Staph. aureus*, and has accordingly about 30 times the activity of 4:4'-diaminobenzophenone. As an aspect of certain other investigations in this laboratory it seemed of interest to prepare and test some aminochalkones and related compounds of type (I), partly in view of the above findings and partly because of the presence of the grouping $-C=C-CO-$ in a number of naturally occurring antibiotics.

4:4'-Diaminochalkone (I; R = NH_2 ; R' = *p*- $\text{NH}_2 \cdot \text{C}_6\text{H}_4$) was prepared by reduction of 4-amino-4'-nitrochalkone, itself obtained by hydrolysing *N*: ω -bis-*p*-nitrobenzylidene-*p*-aminoacetophenone (Scholtz and Huber, *Ber.*, 1904, **37**, 390). 4-Aminochalkone (I; R = H; R' = *p*- $\text{NH}_2 \cdot \text{C}_6\text{H}_4$) was prepared by reduction of the corresponding nitrochalkone with iron and acetic acid, and 4'-aminochalkone (I; R = NH_2 ; R' = Ph) by hydrolysis of *N*: ω -dibenzylidene-*p*-aminoacetophenone. *p*-Amino- ω -cinnamylideneacetophenone (I; R = NH_2 ; R' = $\text{CH}:\text{CH} \cdot \text{C}_6\text{H}_5$) and *p*-amino- ω -furfurylideneacetophenone (I; R = NH_2 ; R' = α -furyl) were prepared in similar fashion by hydrolysing the corresponding di-compounds.

The above compounds were tested against *Staph. aureus* and *Strept. haemolyticus* by a serial dilution method in glucose broth and on a synthetic medium. Although all of them showed some activity (cf. Table) it was in no case of a high order. None showed any activity against *Esch. coli* or *Pseudomonas pyocyanea*.

4-Nitro-4'-aminochalkone.—*N*: ω -bis-*p*-nitrobenzylidene-*p*-aminoacetophenone (3 g.; Scholtz and Huber, *loc. cit.*) was dissolved in ethanol (250 c.c.) and the solution acidified with dilute sulphuric acid. The precipitated sulphate was collected and dissolved in water, and the solution was made alkaline with sodium hydroxide. 4-Nitro-4'-aminochalkone (2.5 g.) separated as an orange-red microcrystalline powder; recrystallised from aqueous ethylene glycol monomethyl ether it had m. p. 220–221° (Found: C, 66.6; H, 4.6; N, 10.4. $C_{18}H_{15}O_3N_2$ requires C, 67.0; H, 4.5; N, 10.4%).

4:4'-Diaminochalkone.—4-Nitro-4'-aminochalkone (0.5 g.) was dissolved in acetic acid (6 c.c.) and the hot solution poured into a suspension of iron filings (2 g.) in dilute acetic acid (30 c.c. of 5%). The mixture was refluxed until all the nitro-compound had gone into solution, and then filtered hot. The filtrate, on cooling, deposited 4:4'-diaminochalkone as a crystalline powder. Recrystallised from ethanol the product formed orange needles (0.35 g.), m. p. 183–184° (Found: C, 75.5; H, 6.4; N, 11.5. $C_{18}H_{14}ON_2$ requires C, 75.5; H, 6.2; N, 11.8%); in pyridine solution it showed the blue fluorescence in ultra-violet light characteristic of 4-aminochalkones (Pfeiffer *et al.*, *Annalen*, 1925, **441**, 228), and on treatment with benzaldehyde it gave a dibenzylidene derivative, m. p. 180–181° (Found: N, 7.0. $C_{20}H_{18}ON_2$ requires N, 6.8%).

4'-Aminochalkone.—Prepared by treatment of *N*: ω -dibenzylidene-*p*-aminocetophenone with dilute sulphuric acid, 4-aminochalkone had m. p. 105–106°. Dilthey, Neuhaus, Reis, and Schommer (*J. pr. Chem.*, 1930, **124**, 81) give m. p. 108°.

4-Aminochalkone.—4-Nitrochalkone (Sorge, *Ber.*, 1902, **35**, 1068) (1 g.) was dissolved in hot acetic acid (3 c.c.) and added to a suspension of iron filings (2 g.) in dilute acetic acid (30 c.c. of 5%). The mixture was heated for 2 hours on the steam-bath, filtered, and cooled. The 4-aminochalkone which separated was recrystallised from aqueous ethanol, and thus obtained as deep yellow plates, m. p. 151–152°. Rupe and Porai-Koschitz (*Chem. Zentr.*, 1906, II, 1761), who prepared the substance by a different route, give m. p. 151°.

p-Amino- ω -cinnamylideneacetophenone.—N : ω -Dicinnamylidene-p-aminoacetophenone (Scholtz and Huber, *loc. cit.*) (3.6 g.) was dissolved in a mixture of ethanol (20 c.c.) and dilute sulphuric acid (5 c.c. of 2N), and the solution was heated on the steam-bath for 10 minutes and then cooled. The precipitated sulphate was collected and dissolved in water, and the solution was made alkaline with sodium hydroxide. The free base which separated was recrystallised from aqueous ethanol; it formed long yellow needles (2.1 g.; 83%), m. p. 159–160° (Found: C, 81.6; H, 6.3; N, 5.9. $C_{17}H_{15}ON$ requires C, 81.9; H, 6.2; N, 5.8%).

N : ω -Difurfurylidene-p-aminoacetophenone.—p-Aminoacetophenone (2.7 g.) and furfuraldehyde (3.85 g.) were dissolved in ethanol (25 c.c.), and cooled to 0°, a solution of potassium hydroxide (1.08 g.) in ethanol (20 c.c.) was added, and the mixture was allowed to stand overnight. The crystalline material which separated was recrystallised from ethanol. The compound formed yellow needles (4 g.), m. p. 103–104° (Found: C, 74.6; H, 4.4; N, 5.1. $C_{18}H_{13}O_5N$ requires C, 74.2; H, 4.5; N, 4.8%).

p-Amino- ω -furfurylideneacetophenone.—N : ω -Difurfurylidene-p-aminoacetophenone was hydrolysed with sulphuric acid in the normal manner (see above). Recrystallised from water, the compound formed yellow needles, m. p. 113–114° (Found: C, 72.9; H, 5.3; N, 6.6. $C_{18}H_{11}O_5N$ requires C, 73.2; H, 5.2; N, 6.7%).

The microbiological assays were carried out in the laboratories of Glaxo Laboratories Ltd., to whom our thanks are due. Grants from the Agricultural Research Council are gratefully acknowledged.—UNIVERSITY CHEMICAL LABORATORY, CAMBRIDGE. [Received, December 19th, 1946.]

Some New Condensation Products of Ethyl cyclopentanone-2-carboxylate with Aromatic Amines.

By H. C. BARANY and M. PIANKA.

FOR the formation of substituted anilides of cyclopentanone-2-carboxylic acid a slight modification of the method of Blount, Perkin, and Plant (*J.*, 1929, 1983) was employed. 0.025 Mole of the amine was gradually added to 0.1 mole of boiling keto-ester containing 0.5 c.c. of pyridine. The mixture was boiled for 2 minutes, cooled, and allowed to crystallise. In some cases crystallisation set in only after some days. Crystals were filtered off, washed with cold ethanol, and treated with a 4% sodium hydroxide solution to free them from any anil formed. The solution was filtered and acidified with dilute acetic acid. The precipitate was filtered off, dried, and recrystallised from ethanol or amyl alcohol. The condensation products prepared are shown in the table opposite.

The condensation products were coupled in alkaline solution with phenyldiazonium chloride, yielding dyes insoluble in water, but soluble in lower alcohols, acetone, and ether, and ranging in colour from lemon-yellow to orange-red.

On application of the film strip test (Weissberger and Porter, *J. Amer. Chem. Soc.*, 1943, **65**, 1502), consisting of immersing an exposed strip of photographic film in a 3% sodium carbonate solution of equal weights of the anilide to be tested and *NN*-diethyl-p-phenylenediamine hydrochloride for 5 minutes, rinsing with water, and bleaching out the silver and silver halide, coloured strips ranging from greenish-yellow to light brown were obtained.

Mr. Edgerton and the Directors of Dufay-Chromex Limited are thanked for permission to publish this note and Mr. H. D. Murray and Mr. B. Gluck for suggesting the use of the anilides in colour photography.—RESEARCH LABORATORIES, DUFAY-CHROMEX LIMITED, ELSTREE, HERTS. [Received, December 9th, 1946.]

Some Applications of Surface Chemistry to Problems in Colloid Science.

THE TILDEN LECTURE, DELIVERED BEFORE THE CHEMICAL SOCIETY ON FEBRUARY 6TH, 1947,
AND AT THE UNIVERSITY COLLEGE OF NOTTINGHAM ON MARCH 18TH, 1947.

By A. E. ALEXANDER, B.Sc., M.A., Ph.D.

SURFACE chemistry, or surface physical chemistry as it might more appropriately be termed, is concerned with the study of interfaces, generally those of macroscopic area. The field is now an extensive one and for that reason this lecture will be restricted to the three interfaces air-water, oil-water, and solid-liquid, which are of particular relevance to typical colloidal systems such as foams, emulsions, proteins, pastes, bacteria, etc. One important aspect, namely, reactions at interfaces, was surveyed by Professor Rideal in his recent Liversidge Lecture.¹

In order to appreciate the results an outline of the principal experimental techniques, particularly those of more recent development, is desirable.

The study of insoluble monolayers at the air-water surface, based upon the classical work of Langmuir and of Adam, and later extended by Rideal, Harkins, and many others, undoubtedly forms the basis of our present knowledge of surface phenomena. The principal measured quantities of the monolayer are its surface pressure, Π ($\Pi = \gamma_{\text{water}} - \gamma_{\text{film}}$), its surface potential, ΔV ($\Delta V = V_{\text{water}} - V_{\text{film}}$), and its mechanical properties (viscosity and elasticity), all measured as a function of the molecular area (A).

Several techniques for the automatic recording of Π - A and ΔV - A curves have been devised; ² these are particularly useful for examining phase changes and stability ranges in condensed monolayers. A simple film balance recently described ³ makes the accurate study of Π - A curves readily accessible.

Condensed monolayers on water can frequently be transferred to a solid surface by a simple dipping process, and layers many molecules thick have thus been built up. These "multi-layers," or "built-up films" as they are termed, find a number of applications, particularly where very thin layers of known thickness are required.⁴

Oil-water interfaces are clearly more directly related to emulsion and biological systems than are air-water interfaces, but the study of insoluble monolayers there has proved much less amenable. However, accurate Π - A curves can now be measured by means of a technique based upon the ring method for surface tension.⁵ Some studies of "interfacial potentials" (ΔV) and of the mechanical properties of such films have also been carried out.⁶

With adsorbed films at mobile interfaces recent interest has been largely concerned with the study of rates of adsorption and desorption. Slow changes can readily be followed by any of the standard methods for boundary tension; for rapid adsorptions the oscillating-jet method recently developed and extended to oil-water interfaces,⁷ and a method utilising surface potentials,⁸ are available.

As regards adsorbed films at the solid-liquid interface, mention may be made of a recent simple method for surface-area determination of fine powders. It merely involves using long-chain polar compounds, in organic media, as adsorbates, and determining the concentration before and after adsorption by spreading as a monolayer on a film balance.⁹ The adsorption isotherm and the saturation uptake, giving the specific surface, are obtained in the usual manner, a value of 20 Å.² per long-chain molecule being assumed at the saturation point.

Having outlined the basic techniques, it is now possible to survey those results which bear directly upon a number of problems in colloidal systems.

The first problem considered will be the proteins, or rather certain aspects connected with them. In addition to their obvious biological importance proteins are common stabilising agents for foams and emulsions, an aspect discussed in more detail below.

Despite their solubility in water, proteins can usually be spread quantitatively as homogeneous monolayers at both air-water and oil-water interfaces. Such monolayers have been extensively studied in the hope of throwing some light upon the structure of the native protein molecule, as well as upon the formation and structure of protein membranes. In addition, attempts have been made recently to determine the molecular weight of proteins from Π - A curves of monolayers in the gaseous state.¹⁰ The technique here is not simple, since measurements have to be made at very large areas and therefore at minute surface pressures. As an illustration of the method, egg albumin has given values of 40,000¹⁰ and 44,000,¹¹ close to the

accepted value for this protein in solution. In the case of haemoglobin the "surface molecular weight" of 12,000 at the air-water interface indicates splitting into some five or six fragments (cf. results for haemoglobin at an oil-water interface, mentioned below).

At the air-water interface the monolayers from widely different proteins are remarkably similar as regards their Π - A curves, although their viscosity and elasticity characteristics may vary considerably. Spreading appears to be accompanied by the complete loss of solubility and, in general, of enzymatic and specific immunological properties, indicating very radical and irreversible changes in structure. Such changes are believed to arise from the polypeptide chains in the protein molecule, originally coiled in some way so as to give a corpuscular form, being unrolled and reorientated on the surface by the action of the very asymmetric field at the interface. Other notable features are the ready formation of two-dimensional elastic gels showing marked hysteresis, and the ease of compression to areas (often less than 10 Å.² per residue) which appear too small for a close-packed monolayer. Oil-water interfaces of high interfacial tension show very similar phenomena, but as the tension is reduced the protein molecules appear to suffer less drastic changes (see also below).

Early speculations concerning the molecular structure of protein monolayers were not very conclusive, largely because of insufficient knowledge of the behaviour of linear polymers at interfaces, and of the bonding between the polar groups present, particularly between $>C=O$ and $H-N<$ in the main chain, and groups such as $-COO^-$ and NH_3^+ in the side chains. A recent study¹² of monolayers of synthetic linear polymers of known structure (*e.g.*, poly-acrylates, poly-methacrylates, nylons, etc.) has enabled the contribution from the first of the above factors to be assessed much more precisely. Collapse of such films, and probably therefore of proteins too, leads to the formation of a thickened layer or overfilm rather than to a looping of the chains beneath the surface as previously believed by some workers. It may be mentioned that films built up by the multilayer technique from monolayers of amorphous polymers have been shown by electron diffraction to possess a much higher degree of order than those formed by the more usual methods.¹³

The interaction between the polar groups in proteins, in particular the extent of hydrogen bonding between the $>C=O$ and $H-N<$ groups of adjacent chains, has been investigated by comparing monolayers of simple paraffin-chain compounds containing the $-CO\cdot NH-$ group (*e.g.*, acetamides, ureas) with the analogous esters and ketones, where intermolecular hydrogen bonding is impossible.¹⁴ The replacement of $-O-$ or $-CH_2-$ by $-NH-$ brings about striking changes in monolayer properties, and the conclusion is reached that intermolecular hydrogen bonding is certainly of major importance in protein monolayers. This approach enables reagents known to bring about changes in native proteins (*e.g.*, urea) to be assessed as regards their action upon the keto-imino-hydrogen bonds.

Turning now to two closely related classical colloidal systems, namely, foams and emulsions, the principal problems arising are as follows: the adsorption of the stabilising agent during the dispersion process, the structure of the adsorbed film and its importance in relation to the gross stability, and finally the desorption of stabilising agent as re-aggregation occurs. Surface chemistry has been able to supply considerable information about all of these problems, although it must be confessed that the picture is by no means complete.

The rate of adsorption at an air-water interface, which is usually followed by surface-tension measurements, is found to occur much more slowly than predicted by classical diffusion theory.¹⁵ In the case of soaps and dyes, for example, the ratio of the calculated to the observed rate may be 10^6 or more. The hindrance to diffusion has usually been ascribed to an electrostatic potential barrier at the surface, arising from the presence of the adsorbed layer of long-chain ions, but the fact that similar anomalies arise with un-ionised compounds (*e.g.*, β -phenyl-propionic acid at pH 2) shows that this factor is certainly not the major one. The rate of attainment of equilibrium is accelerated by the presence of other surface-active substances, by insoluble monolayers, and by replacing the air by an oil phase.⁸ Such experiments suggest that the main factor in these slow diffusions arises from the steric hindrance which a long hydrocarbon chain encounters when endeavouring to penetrate a comparatively close-packed monolayer. Anomalously slow adsorption of long-chain polar compounds can also occur from an oil phase to an aqueous interface, a phenomenon closely related to their well-known tendency to aggregate in organic media.¹⁶

Desorption, even with molecules of not particularly complex structure (*e.g.*, β -phenyl-propionic acid), appears to be an equally hindered process, although little has been done on this aspect, particularly at oil-water interfaces. Compression of a film adsorbed at an air-

water interface may even lead to the adsorbate separating out on the surface as a crystalline or liquid aggregate.¹⁷

The structure of the stabilising film in foams and emulsions, in particular whether the thickness is uni- or multi-molecular, can frequently be inferred indirectly from surface studies. In the case of water-soluble compounds (*e.g.*, soaps, and the lower fatty acids or alcohols) an equation of state can be deduced from the study of homologous longer-chain compounds which form insoluble monolayers, and this enables the adsorption, if confined to a monolayer, to be calculated at both oil-water and air-water interfaces.¹⁷ The values thus calculated for the two most accurately studied compounds are seen from the data below to agree closely with the experimental ones obtained by McBain and his co-workers using the microtome method.

Solute.	Calc.	Adsorption.	Exptl.
β -Phenylpropionic acid	8.3×10^{-8} g./cm. ²	7.7×10^{-8} g./cm. ²	
Laurylsulphonic acid	5.7×10^{-10} g.-mol./cm. ²	$5.2-5.7 \times 10^{-10}$ g.-mol./cm. ²	

The conclusion is therefore drawn that in foams, and by analogy also in emulsions (oil-in-water type), stabilised by water-soluble soaps, the interfacial films are no more than unimolecular in thickness, and are in a highly compressed gaseous (and hence fluid) state, with molecular areas of *ca.* 30 Å.² for simple straight paraffin-chain derivatives. Stabilisation arises chiefly from the marked reduction in the surface energy of the system, although other factors, particularly the surface viscosity of the adsorbed film, also play a part. The close connection between the lowering of interfacial tension and emulsion stability is shown particularly by systems stabilised by "interfacial complexes" formed between a water-soluble soap and organic compounds containing hydroxyl or amino-groups (*e.g.*, cholesterol, long-chain amines) dissolved in the oil phase.¹⁸ The study of oil-water insoluble monolayers shows that in the case of stable oil-in-water emulsions the oil phase will be effectively displaced from the interface by the adsorbed monolayer of stabiliser.⁸

With the heavy-metal or oil-soluble soaps (*e.g.*, magnesium oleate) which stabilise the water-in-oil type of emulsion, the monolayers in equilibrium with the solid soap phase are also in a fluid, gaseous state, but the equilibrium spreading pressures are very much less than in the case of water-soluble soaps, which effectively rules out any stabilisation by a monolayer. The spontaneous formation of visible rigid films by reaction between heavy-metal cations and fatty acids at an oil-water interface indicates stabilisation by solid particles, in agreement with the observation that stable water-in-oil emulsions invariably contain solid soap.¹⁹

Protein solutions in contact with air-water and oil-water interfaces readily give rise to tough visible "skins", a phenomenon first recorded by Ascherson over a century ago, and still very imperfectly understood. In the case of an air-water interface this "surface denaturation" continues until all the protein present has been removed as a coagulum practically devoid of surface activity. At oil-water interfaces, the rate and the extent of these surface changes diminish with decreasing interfacial tension.²⁰ For example, if hæmoglobin is desorbed (by changing the pH) from the surface of a fine emulsion stabilised by sodium cetyl sulphate its molecular weight is unaffected but its ultracentrifuge dissymmetry coefficient has increased from 1.16 to 1.33, indicating some, but not complete, unfolding of the molecule.²¹

The behaviour of monolayers of proteins at air-water and oil-water interfaces suggests very strongly that proteins stabilise foams and emulsions by the formation of multimolecular films or skins rather than by a monolayer, these conferring mechanical protection.

The question of elasticity in adsorbed films is important in relation to the question of thermodynamic stability of foams and emulsions. Monolayers only show elasticity when in the condensed state, and from the study of equilibrium spreading pressures of crystals it would appear that all *condensed* monolayers are unstable with respect to their bulk phase. Accordingly, if an *adsorbed* film exhibits elasticity (as with protein or saponin solutions, and with heavy-metal soaps formed by metathesis at an interface), it would seem probable that its structures is multimolecular rather than unimolecular, and that the system is not in thermodynamic equilibrium.

Mention may be made in passing of Hardy's technique for studying foam stability by measuring the life-time of an air bubble liberated beneath an insoluble monolayer. Appreciable stabilisation is only obtained with coherent monolayers (expanded or condensed), and the stability decreases in the highly condensed state where the monolayers become unstable.²²

Passing now to a consideration of pastes (concentrated dispersions of finely divided solids in a liquid continuum), some recent work⁹ has shed much light upon the influence of surface-

active substances upon their macroscopic properties, such as flow behaviour and sedimentation volume. The adsorption upon polar powders such as sodium nitrate, using paraffin-chain compounds with different polar groups, in benzene or organic solution, was found to be in the following order $\cdot\text{NO}_2 > \cdot\text{CO}_2\text{H} > \cdot\text{OH} > \cdot\text{C}=\text{O}$. Parallel measurements of the coefficient of friction between large crystals showed that the friction was lowered in the same order. With increasing adsorption the ease of flow increases and the sedimentation volume decreases. Adsorption in these systems takes place with the polar groups of the adsorbate molecules oriented towards the polar surface of the crystal, and the hydrocarbon chains extending into the organic liquid. This outer surface of hydrocarbon reduces the interaction between the polar crystals and leads to the observed changes in macroscopic properties.

Finally, brief reference may be made to the application of surface studies to problems of a biological nature. Two examples only will be considered here, although others have been studied in this way (e.g., the mechanism of fat absorption).²³

Hexylresorcinol is a well-known anthelmintic for *Ascaris* and other intestinal worms. *In vitro* tests showed its activity to be considerably affected by the presence of bile salts or other soap-like substances, low concentrations generally producing some activation, but very high ones complete inhibition. Measurement of the surface activities of the various mixtures showed that the inhibition arises from the colloidal soap micelles, which form at the higher soap concentrations, competing with the biological surface for the fixed amount of drug.²⁴ The activation produced by low soap concentrations is related to the increased surface activity of the mixture, leading to an increased rate of penetration.

Similar conclusions have been found to apply to the bactericidal action of phenols in the presence of soaps. Rideal-Walker tests, and measurement of the rates of killing, show that the bactericidal activity increases up to the point where soap micelles start to form, and thereafter decreases.²⁵

OBITUARY NOTICE.

EDMUND BRYDGES RUDHALL PRIDEAUX.

1878—1946.

EDMUND BRYDGES RUDHALL PRIDEAUX was born in Barbados and educated at the Auckland Grammar School and Canterbury College, New Zealand University. His education, following the tradition of his family, was mainly classical; although he devoted himself to science he never lost his love of the classics and throughout his life would turn to them for solace and inspiration.

In 1901 he came to London but moved, in 1906, to the Heriot Watt College, Edinburgh, and thence, in 1909, to Liverpool University. Professor Donnan writes: "I had the great pleasure of welcoming Dr. E. B. R. Prideaux when he came to work in the Muspratt Laboratory of Physical and Electro-chemistry after having spent a year or two of research in the laboratory of Sir William Ramsay at University College, London. As a senior research worker of ability and experience he was a great source of strength to us in Liverpool and he made very valuable contributions to the research output of the laboratory. His lectures to the senior students on physico-chemical calculations were highly appreciated. I think I may claim the honour of having directed his attention to the special study of ionic equilibria in solutions and the various types of electrical potential differences associated therewith.

"Dr. Prideaux was a quiet, thoughtful, and scholarly man of science, and I have the happiest recollections of my association with him during those Liverpool years. He was one of a number of excellent men from New Zealand, including Denham, Stubbs, and Farrow, who contributed greatly to the success of the Muspratt Laboratory and the advance of physical chemistry."

In 1913 Prideaux moved to the Battersea Polytechnic and, in the following year, to the University College of Nottingham. His output of research was increasing rapidly but it received a check due to the outbreak of war. Much of his time was spent in assisting the National Shell-filling Factory at Chilwell and in preparative organic chemistry in connection with the production of β -eucaine. With the end of the war came the great influx of ex-service students, and in their interests he spent himself unstintingly.

Professor Kipping writes: "Dr. Prideaux was deeply imbued with the true scientific spirit which alone enabled him to accomplish the work for which he was distinguished in spite of his conscientious and painstaking preoccupation with his academic duties and, often also, with very inadequate apparatus.

"Although quiet and reserved in unfamiliar surroundings, with some of the attributes of a recluse, he was a kind and genial man and an interesting companion with broad and well informed views and decided opinions on many subjects. Some of the less desirable qualities which so often determine worldly success were, however, entirely foreign to his character; he was too altruistic, lacking in self-assertion and prone to neglect opportunities for his own advancement. It was, doubtless, for this reason that he failed to attain the higher rank in his profession to which he was entitled.

"He was not only, during many years, an accomplished member of my staff but also a highly valued friend."

As a research worker Prideaux was remarkable for his versatility; scarcely a single branch of chemistry escaped his attention, and he published some 90 papers in scientific journals apart from articles on scientific and educational topics. After obtaining the M.A. degree of New Zealand University he completed a research on Kauri resin and was awarded the B.Sc. degree. He continued to work on resins at the Imperial Institute in London in 1902, but then, under Ramsay, turned his attention to fluorine. He discovered the compounds BrF_3 , TeF_6 , and SeF_6 . This work gained him the D.Sc. degree of London University. Fluorine continued to interest him throughout his life, and some 12 of his papers are devoted to this element and its compounds with selenium, tellurium, zirconium, and rubidium.

Phosphorus and its compounds also interested Prideaux, and his electronic formulation of phosphorus pentachloride received wide publicity. He published many papers on phosphoric and boric acids and was a pioneer in the use of modern indicators, and of the hydrogen and quinhydrone electrodes, and, in general, in the practical applications of the electrolytic dissociation theory. With A. T. Ward he devised the first "universal" buffer solution.

The dissociation constants of phenols and of alkaloids, the separation and estimation of pyridine and ammonia, the analysis of nitrotoluenes, benzoates, and salicylates, the spectro-

photometric examination of dyes and indicators, photo-synthetic phenomena in sea water, diffusion and membrane potentials, the corrosion of cement; these and other topics are evidence of the catholicity of Prideaux's tastes in research. In collaboration with F. O. Howitt he contributed valuable papers on the electrophoresis and isoelectric points of proteins and the kataphoresis of insulin. His theoretical papers helped the development of views on molecular structure.

Prideaux wrote several books: "The Theory and use of Indicators," "Problems in Physical Chemistry," and "A Survey of English Elementary Education." He was the author of the volume "Phosphorus" in Newton Friend's Text Book of Inorganic Chemistry, and joint author, with Herbert Lambourne, of the volume "Nitrogen," and with F. C. Laxton of "A Laboratory Course in Elementary Chemistry." He was, moreover, one of the pioneers in popular broadcast talks on scientific topics.

In 1908 Prideaux married the elder daughter of Rowland Bramwell, Esq., of Auckland, New Zealand. In 1946 he resigned his post as Reader in Physical and Inorganic Chemistry in the University College of Nottingham and, in recognition of his services, was awarded the title of *Lector Emeritus*. He then settled, with his wife and daughter, in his home at Canford Cliffs, Bournemouth, hoping to carry on his researches unhampered by the academic duties to which so much of his life had been devoted. The repose he had so richly earned by a life of labour was, however, denied him; he died on the 8th of May, 1946. His memory lives in the hearts of the students and friends who knew and valued him.

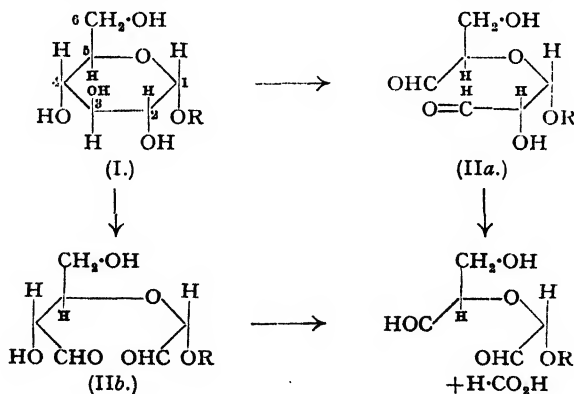

B. D. SHAW.

269. Oxidation of Carbohydrates by the Periodate Ion.

By T. G. HALSALL, E. L. HIRST, and J. K. N. JONES.

The oxidation, with salts of periodic acid, of the methylglycosides of the hexose and pentose sugars and of the disaccharides has been investigated. Sugar derivatives containing hydroxyl groups on each of three adjacent carbon atoms are oxidised with the formation of 1 mol. of formic acid, and conditions have been established for the quantitative estimation of the formic acid. Methyl hexo- and pento-pyranosides and the methyl glycosides of maltose and cellobiose give rise quantitatively to 1 mol. of formic acid, but reducing sugars, methylglycosides of the uronic acids, and methylhexofuranosides yield acidic material equivalent to more than 1 mol. of formic acid per mol. of sugar. The causes of this continued oxidation are discussed.

THE observation by Hudson and Jackson (*J. Amer. Chem. Soc.*, 1936, **58**, 378; 1937, **59**, 994), that the α - and β -methylglucosides yield on oxidation with periodic acid a dialdehyde together with 1 mol. of formic acid, affords a possible method of estimating the number of end groups present in a polysaccharide which has terminal groups of the type (I), provided that the non-terminal groups are such that they do not yield formic acid. Such a method should therefore be applicable to a wide range of polysaccharides, including starch, cellulose, and glycogen, which possess chains of 1:4-linked hexopyranose residues, but hitherto attempts to make use of this procedure have encountered difficulty in that the oxidation is not arrested at

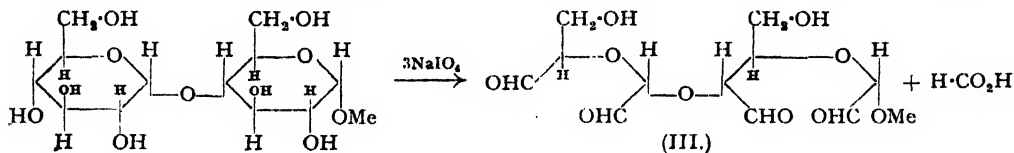

the stage when 1 mol. of formic acid has been liberated from the terminal group (Davidson, *J. Textile Inst.*, 1941, **32**, T, 109). Nevertheless the reaction has been used successfully in other

ways in the study of polysaccharides. For example, the stepwise degradation of laminarin, which consists of 1 : 3-linked residues, has been described by Barry (*Nature*, 1943, 152, 538) and by Dillon (*ibid.*, 1945, 155, 546), and attempts have been made to estimate the formaldehyde produced from the reducing end of the chain in starch dextrins (Caldwell and Hixon, *J. Biol. Chem.*, 1938, 123, 595).

In view of our interest in methods for estimating end groups in polysaccharides we decided to undertake a more detailed survey of the conditions requisite for the prevention of over-oxidation and thus facilitate the development of a method of estimation which would possess many advantages over the present available techniques. This was all the more necessary in that we had found in the course of experiments on plant gums, in which we had hoped to remove certain side chains with the aid of periodic acid, that difficulties due to over oxidation were encountered.

As a preliminary, therefore, to the application of the periodate method of oxidation to the polysaccharides, model experiments were carried out with simple sugars containing groups similar to those present in polysaccharides. These included α -methylglucopyranoside, α -methylgalactopyranoside, α -methylmannopyranoside, α -methyl-*D*-mannofuranoside, β -methyl-maltoside, β -methylcellobioside, β -methyl-*L*-arabopyranoside, α -methyl-*D*-xylopyranoside, amygdalin, mannitol, lactose, lactal, and the methyl ester of α -methyl-*D*-galacturonoside. Control experiments with formic acid, ethylene glycol, and oxalic acid were also carried out.

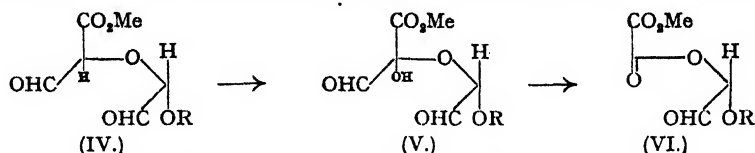

It was our aim to estimate small amounts of formic acid, and this we found practicable only when the excess of periodate had been destroyed by the addition of ethylene glycol with the resultant formation of formaldehyde and sodium iodate, both of which were without action on methyl-red used as indicator for the titration of the formic acid. Sodium periodate slowly destroys formic acid, and the estimated amount of the latter may be low unless precautions are taken. It was found, however, that the oxidation of formic acid is considerably slowed down in the presence of sodium iodate, and, as this substance is always formed by reduction of the periodate, loss of formic acid during the period of oxidation is negligible. Sodium periodate gives satisfactory results for the oxidation of small amounts of methylhexopyranosides and pentopyranosides, all of which on oxidation give 1 mol. of formic acid. On the other hand when this reagent is applied to the methylglycosides of the reducing disaccharides oxidation proceeds beyond the stage represented by (III), and ultimately considerably more than 1 mol. of formic acid is produced per mol. of methylglycoside. The rate of production of formic acid is much slower, however, after the liberation of 1 mol., but with a large excess of sodium periodate as oxidising agent there is not an easy differentiation between the two stages of the reaction.

We therefore examined other salts of periodic acid which had lower solubility and would provide reaction solutions of lower acidity. Most of the salts examined were unsatisfactory since they possessed either basic or strongly acidic characteristics. Potassium metaperiodate, however, is only very slightly soluble in water and gives a solution having a pH of about 4. Using this salt and keeping the concentration of formic acid produced to a low value (*ca.* 10 mg. per 100 c.c.), we were able to obtain consistent and reliable figures for the amount of formic acid produced. This lowering of concentration of the periodate ion, however, considerably reduces the rate of reaction, and instead of being complete in 6 hours it now requires 150 hours at 15°. On oxidation with this reagent the methylglycosides of (a) the hexose, (b) the pentose sugars, and (c) the reducing disaccharides gave normal amounts of formic acid. The methylglycosides of uronic acids and of hexofuranosides underwent further oxidation with the formation of additional amounts of acidic material. Similar behaviour was shown by reducing sugars.

The oxidation of the glycosides of the uronic acids has been the subject of previous publications. Huebner, Lohmar, Moore, and Link (*J. Biol. Chem.*, 1945, 159, 502) demonstrated that, in the oxidation of zinc borneol glucuronoside, more than 1 mol of acid was produced per mol. of glucuronoside and that one of the reaction products was bornyl formate. They suggested that the uronic acid residue, after undergoing oxidation with the formation of formic acid and the dialdehyde (IV), was further oxidised by the periodate. The first step in this oxidation, it was suggested, was the oxidation of the active hydrogen situated on the carbon atom between

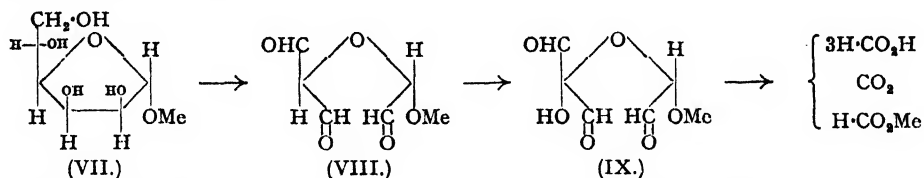

two carbonyl groups to a hydroxyl group (V). This would result in the formation of a substance which in its hydrated form contains hydroxyl groups on adjacent carbon atoms and would

undergo further oxidation with periodate with the formation of an ester of oxalic acid (VI). Once this stage had been reached the ester, which would be unstable in water, could hydrolyse to oxalic acid and a product which could then undergo further oxidation to formic acid and an ester of formic acid.

The stage in which the aldehyde (IV) is converted into the α-hydroxy-aldehyde (V) has been investigated by Sprinson and Chargaff (*J. Biol. Chem.*, 1946, **164**, 443). These workers demonstrated that substances such as malonic acid and its derivatives—substances which contain a hydrogen atom combined to a carbon atom situated between two carbonyl groups $\left(\begin{array}{c} \text{O} & \text{H} & \text{O} \\ \parallel & | & \parallel \\ -\text{C} & -\text{C} & -\text{C}- \end{array} \right)$ —are all capable of being oxidised to the corresponding hydroxy-compound which may then undergo further oxidation [cf. the work of Neuberger (*J.*, 1941, 47) on the oxidation of ethyl *N*-benzoylglucosamate].

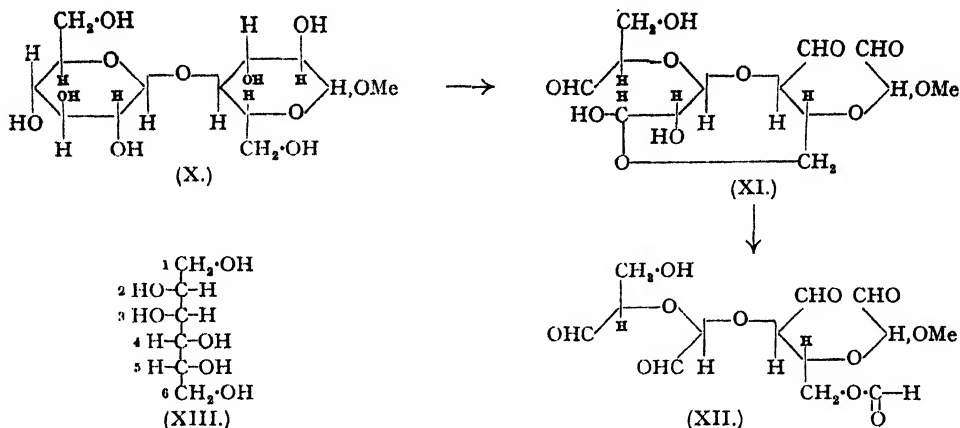

We have found that whenever this secondary type of oxidation occurs free iodine is ultimately produced and the amount of acid in the solution falls. The mode of origin of the iodine is obscure, but the simplest explanation would be to ascribe its formation to the well-known reaction between sodium iodide and sodium iodate in acid solution, the sodium iodide arising in turn from reduction of sodium iodate during oxidation on the activated carbon atom. A typical example of the grouping which undergoes further oxidation, with liberation of free iodine, is shown in (VIII) which is the intermediate product obtained by the periodate oxidation of α-methylmannofuranoside (VII). Attack at the activated hydrogen would yield (IX) which would readily undergo further oxidation giving 3 mols. of formic acid, 1 mol. of methyl formate, and 1 mol. of carbon dioxide.

The rate of oxidation and rate of formation of formic acid varies with the configuration of the glycoside. Those glycosides, such as the arabo-, galacto-, and manno-pyranosides, which contain *cis*-hydroxyl groups, are oxidised relatively quickly, whilst those glycosides which contain *trans*-hydroxyl groupings, such as the glucopyranosides, are oxidised more slowly (cf. "Organic Reactions", Vol. 2, p. 353, Wiley, New York). The presence of *cis*-hydroxyl groups, however, is not the only factor which decides the rate of formation of formic acid. This is dependent also upon the rate of oxidation of the α-hydroxy-aldehyde, which is a comparatively slow reaction. Furthermore, the methylglycosides of maltose and cellobiose, both of which contain glucopyranose residues only, give formic acid at different rates. For example, methylmaltoside yields 1 mol. of formic acid in about 100 hours, whilst the cellobioside gives only 0.86 mol. in this time and 300 hours are necessary for the liberation of one equivalent of acid. This low yield of formic acid from methylcellobioside (X) could be explained by the intermediate formation of a lactol grouping such as (XI) which on further oxidation would yield not free formic acid but a formyl ester (XII). An examination of the model of the methylcellobioside molecule (and similarly of the sucrose molecule) reveals that the hydroxyl groups are so situated in space that lactol formation can readily take place, whereas the configuration of the groups in the molecule of the methylmaltoside is unfavourable for the formation of lactol groupings.

This oxidation of an intermediate lactol with formation of an ester of formic acid instead of free formic acid receives support from a study of the oxidation of mannitol. The oxidation of this hexahydroxy-alcohol yields two mols. of formaldehyde and formic acid. A quantitative

estimation of the formic acid, however, showed that the yield of this acid reached 95% of 4 mols. under the standard conditions and was not complete until the reaction had proceeded for about

400 hours. The primary oxidation of mannitol (XIII) may occur in one of five places in the molecule. It may give either (a) a pentose, (b) a tetrose, or (c) glyceraldehyde as the main reaction product. Other things being equal, reactions (a) and (b) will predominate. The pentose and tetrose which result from this oxidation may exist either as *aldehyde*-sugars or as ring structures. Should oxidation of the ring structure or lactol form occur, then a formic ester will be produced with a consequent lowering in the yield of titratable formic acid. On standing in water these esters will undergo hydrolysis and further oxidation, and a consequent slow rise in the titration figure will result. This formation of ester groupings from the oxidation of a lactol is small, since in no case have we encountered a yield of formic acid of less than 90% of the theoretical in our experiments on the oxidation of the sugar glycosides under the standardised conditions. In the oxidation of the reducing sugars, however, low yields of formic acid are produced when using our standardised reaction conditions. In certain instances, however, side reactions, with the formation of iodine, explain, in part, the low yields of formic acid produced in this complex oxidation reaction.

EXPERIMENTAL.

Oxidation with Sodium or Potassium Periodate. General Procedure.—Reactions were carried out in diffused light at 15–20° (with shaking when potassium periodate was used), in 500 c.c. stoppered bottles which had been cleaned with chromic acid and steamed out.

Sodium metaperiodate was prepared from sodium paraperiodate by recrystallisation from nitric acid. It contained no free acid since on addition of excess of ethylene glycol to its aqueous solution, sodium iodate neutral to methyl-red was formed. The ethylene glycol required was purified by distillation over solid potassium hydroxide. It was neutral to methyl-red.

The material (sufficient to give *ca.* 10 mg. of formic acid) was weighed out into a 500 c.c. stoppered bottle and dissolved or suspended in water. Excess of approximately 0.3M-sodium periodate was then added, followed by potassium chloride (5 g.) (if the oxidation was to be carried out with potassium periodate) and water to the requisite volume (usually 120 c.c.). Portions (either 10 or 20 c.c.) of the solution were withdrawn at intervals, excess of ethylene glycol was added to remove the residual periodate, and the formic acid was then determined either by titration with 0.01N-sodium hydroxide, using methyl-red as indicator, or after addition of potassium iodide by determination of the liberated iodine with 0.01N-thiosulphate. Blank experiments showed that under these conditions sodium iodate, formaldehyde, and ethylene glycol do not interfere with the estimation of formic acid and that the formic acid produced is not destroyed.

Oxidations with sodium metaperiodate. (1) α -Methylglucoside (87 mg.) was dissolved in water (115 c.c.), and sodium periodate solution (15 c.c.; 0.2M) was added. Portions of the solution (25 c.c.) were removed at intervals; ethylene glycol (approximately 0.1 c.c.) was added, and the formic acid titrated after a few minutes with 0.01N-sodium hydroxide. Titres: 6.3 c.c. (6 hours), 8.3 c.c. (22½ hours), 8.35 c.c. (47 hours), equivalent to 99.5% recovery.

After completion of oxidation a portion of the solution (50 c.c.) was extracted continuously with ether until the final extracts were neutral. The extracts were concentrated, and then required 18.8 c.c. of 0.01N-sodium hydroxide equivalent to 108% recovery of formic acid. The sodium formate obtained on evaporation of the neutralised solution gave, on heating with sulphuric acid (*d* 1.84) in a gas analysis apparatus, carbon monoxide corresponding to 99.4% of the theoretical yield of formic acid. The three different methods of determination gave reasonably concordant results, and the determination *via* carbon monoxide proves that the acid produced is formic acid.

(2) β -Methylmaltoside monohydrate (489.5 mg.) was dissolved in water (140 c.c.), and sodium periodate solution (60 c.c.; 0.275M) was added. The solution was left at 15–20°, samples (10 c.c.) were

withdrawn at intervals, ethylene glycol was added, and the solution titrated with 0.01N-barium hydroxide. At the same time the consumption of periodate and the change of optical rotation were determined.

Time (hours).	$[\alpha]_D^{19.5^\circ}$.	Formic acid produced (mols. per mol. of maltoside).	Consumption of periodate (mols. per sugar residue).
0	+176°	nil	nil
0.6	— 33	0.48	2.58
1.5	— 45	0.65	2.84
5.1	— 100	0.89	2.97
30	— 62	1.19	3.61

The reaction was not finished after 30 hours, since formic acid continued to be produced. The last figure for formic acid (1.19 mols.) is considerably more than the theoretical value (1.0 mol.). High results were obtained also with other disaccharide derivatives, and the occurrence of over-oxidation even under carefully controlled conditions rendered the use of sodium periodate unsatisfactory for quantitative work, except when the reagent was employed in very slight excess.

Oxidations with potassium metaperiodate. (3) Mannitol was oxidised to show that formaldehyde and formic acid were unaffected by the oxidation conditions used above. The mannitol (28 mg.) was dissolved in water (110 c.c.) containing sodium periodate (11 c.c.; 0.236M) to which potassium chloride (5 g.) had been added. Titration of the liberated acid after addition of excess of glycol was made at intervals on portions of the solution. Found, mols. of formic acid per mol. of sugar: 3.56 (3 hours), 3.60 (98 hours), 3.80 (145 hours), 3.80 (194 hours), 3.88 (266 hours), 3.96 (338 hours), 3.96 (580 hours). Two other experiments gave similar results.

(4) α -Methyl-*d*-glucoside (81 mg.) was dissolved in water (110 c.c.) containing potassium chloride (5 g.), and sodium periodate (10 c.c.; 0.27M) was added. At intervals samples (10 c.c.) were withdrawn and titrated. Found, mols. of formic acid per mol. of methylglucoside: 0.28 (1 hour), 0.43 (5½ hours), 0.69 (23 hours), 0.90 (51 hours), 0.91 (72 hours), 0.94 (170 hours), 0.97 (220 hours), 1.04 (460 hours).

(5) α -Methyl-*d*-galactopyranoside (111 mg.) was dissolved in water (110 c.c.), and potassium chloride (5 g.) and sodium periodate (10 c.c.; 0.236M) were added. The bottle and contents were then shaken and at intervals samples (10 c.c.) were withdrawn and titrated. Found, mols. of formic acid per mol. of methylgalactoside: 0.95 (67 hours), 0.99 (120 hours), 1.01 (192 hours), 1.01 (230 hours), 1.03 (500 hours).

(6) α -Methyl-*d*-mannopyranoside (82 mg.) was dissolved in water (110 c.c.) containing potassium chloride (5 g.), and sodium periodate (10 c.c.; 0.282M) was added. The bottle and contents were shaken and at intervals samples (10 c.c.) were withdrawn and titrated. Found, mols. of formic acid per mol. of methylmannoside: 0.67 (68 hours), 0.85 (121 hours), 0.93 (168 hours), 0.97 (211 hours), 0.95 (289 hours), 0.96 (405 hours).

(7) β -Methyl-*l*-arabopyranoside (89 mg.) was dissolved in water (110 c.c.) containing potassium chloride (5 g.), and sodium periodate (10 c.c.; 0.236M) was added. The bottle and contents were shaken and at intervals samples (10 c.c.) were withdrawn and titrated. Found, mols. of formic acid per mol. of glycoside: 0.97 (47 hours), 0.99 (91 hours), 0.99 (143 hours), 1.01 (165 hours), 1.01 (215 hours), 1.02 (281 hours), 1.04 (362 hours), 0.99 (506 hours).

(8) α -Methyl-*d*-xylopyranoside (107 mg.) was oxidised as described for the oxidation of the arabinoside. Found, mols. of formic acid per mol. of glycoside: 0.71 (47 hours), 0.89 (91 hours), 0.93 (143 hours), 0.98 (165 hours), 0.98 (215 hours), 1.00 (287 hours), 1.02 (362 hours).

(9) β -Methylmaltoside monohydrate (249.7 mg.) was dissolved in water (70 c.c.) containing potassium chloride (2.5 g.), and sodium periodate solution (30 c.c., 0.275M) was then added. The whole was placed in a stoppered bottle which was continuously shaken. At intervals samples (10 c.c.) were withdrawn, and after addition of ethylene glycol the formic acid was titrated with 0.01N-barium hydroxide using methyl-red as indicator. Found, mols. of formic acid per mol. of maltoside: 0.13 (1½ hours), 0.53 (20 hours), 0.75 (43 hours), 0.83 (66 hours), 0.92 (91 hours), 1.01 (163 hours), 1.03 (192 hours), followed by a very slow rise. One mol. of formic acid is liberated per mol. of maltoside in 150 hours.

(10) β -Methylcellobioside (106 mg.) was dissolved in water (110 c.c.) containing potassium chloride (5 g.), and sodium periodate (10 c.c., 0.28M) was added. At intervals samples (10 c.c.) were withdrawn and titrated. Found, mols. of formic acid per mol. of cellobioside: 0.69 (43 hours), 0.84 (91 hours), 0.87 (144 hours), 0.88 (185 hours), 0.89 (244 hours), 0.91 (291 hours).

(11) Amygdalin (173 mg.) was oxidised as described above (cf. Courtois and Valentino, *Bull. Soc. Chim. biol.*, 1944, **26**, 469). Found, mols. of formic acid per mol. of glycoside, 1.05 (47 hours), 1.28 (91 hours), 1.53 (143 hours), 1.83 (165 hours), 1.90 (215 hours), 2.03 (287 hours), 2.08 (362 hours), 2.00 (506 hours).

(12) Sucrose (111 mg.) was dissolved in water (105 c.c.) containing potassium chloride (5 g.), and sodium periodate (15 c.c.; 0.307M) was added. At intervals samples (20 c.c.) were withdrawn and titrated. Found, mols. of formic acid per mol. of sucrose: 0.84 (170 hours), 0.84 (195 hours), 0.92 (267 hours), 0.91 (315 hours), 0.91 (431 hours).

(12) Zinc borneol glucuronoside (110 mg.) was dissolved in water (105 c.c.) containing potassium chloride (5 g.), and sodium periodate (5 c.c., 0.285M) was added. At intervals samples (20 c.c.) were withdrawn and titrated. Found, mols. of formic acid per mol. of compound: 2.34 (162 hours), 1.74 (188 hours), 1.40 (210 hours), 1.06 (307 hours). The solution became brown owing to the separation of iodine and oily droplets of bornyl formate were observable.

(13) The methyl ester of α -methylgalacturonoside (21.95 mg.) was dissolved in water (200 c.c.) containing potassium chloride (5 g.), and sodium periodate (5 c.c., 0.308M) was added. At intervals samples (20 c.c.) were withdrawn and titrated. Found, mols. of formic acid per mol. of sugar: 0.22 (3 hours), 0.79 (25 hours), 1.23 (49 hours), 1.70 (74 hours), 2.18 (117 hours), 3.74 (171 hours), 4.22 (219 hours), 4.22 (335 hours).

(14) Lactose hydrate (94 mg.) was dissolved in water (100 c.c.) containing potassium chloride (5 g.)

and sodium periodate (20 c.c., 0.2M) was added. At intervals samples (10 c.c.) were withdrawn and titrated. Found, mols. of acid per mol. of lactose hydrate : 1.85 (42 hours), 2.87 (95 hours), 3.27 (142 hours), 3.68 (185 hours), 4.13 (263 hours), 2.41 (427 hours) (iodine was liberated at this stage with a resultant fall in acid titre).

(15) Lactal (160 mg.) was dissolved in water (100 c.c.) containing potassium chloride (5 g.) and sodium periodate (20 c.c.; 0.28M) was added. At intervals samples (10 c.c.) were withdrawn and titrated. Found, mols. of acid per mol. of lactal : 0.87 (42 hours), 1.00 (95 hours), 1.09 (142 hours), 1.17 (185 hours), 1.50 (263 hours), 2.06 (427 hours).

(16) α -Methyl-*D*-mannofuranoside (106 mg.) was dissolved in water (110 c.c.) containing potassium chloride (5 g.), and sodium periodate (10 c.c.; 0.236M) was added. At intervals samples (10 c.c.) were withdrawn and titrated. Found, mols. of acid per mol. of glycoside : 1.5 (47 hours), 2.0 (91 hours) (at this stage iodine began to be liberated and the alkali titre fell), 0.43 (143 hours) (all the periodate had then been converted into iodate and iodine).

(17) Oxalic acid dihydrate (27.02 mg.) was dissolved in water (115 c.c.) containing potassium chloride (5 g.), and sodium periodate solution (5 c.c.; 0.3072M) was added. At intervals samples were withdrawn and titrated. Found, mols. of oxalic acid : 0.43 (95 hours), 0.34 (120 hours), 0.31 (144 hours), 0.18 (430 hours), 0.12 (602 hours).

The authors thank the British Cotton Industry Research Association for a Shirley Fellowship awarded to one of them (T. G. H.), and Imperial Chemical Industries Ltd. for a grant.

270. The Chloromethylation of Naphthalene and of Tetralin.

By G. M. BADGER, J. W. COOK, and G. W. CROSBIE.

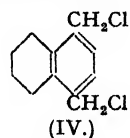

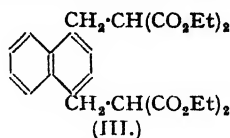

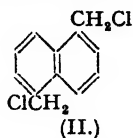

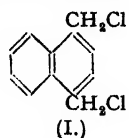

Chloromethylation of naphthalene with boiling aqueous formaldehyde and hydrochloric acid gives a mixture from which 1 : 4-bischloromethylnaphthalene and 1 : 5-bischloromethylnaphthalene have been isolated. From tetralin, 5 : 8-bischloromethyl-1 : 2 : 3 : 4-tetrahydronaphthalene has been obtained.

FROM the products of the chloromethylation of 1-chloromethylnaphthalene, Anderson and Short (*J.*, 1933, 485) obtained a crude bischloromethylnaphthalene, m. p. 130—145°, which they were unable to purify. They regarded this as being largely the 1 : 5-derivative because, on reduction, they isolated and characterised 1 : 5-dimethylnaphthalene. Furthermore, on oxidation of the crude bischloromethylnaphthalene, they obtained the corresponding 1 : 5-dicarboxylic acid. Manske and Ledingham (*Canadian J. Res.*, 1939, 17, 14) investigating the high-boiling residues resulting from Cambron's (*ibid.*, p. 10) chloromethylation of naphthalene, obtained a supposedly pure bischloromethylnaphthalene, m. p. 144°, which they regarded as the 1 : 5-derivative. Evidence for this was obtained by conversion into the dinitrile, hydrolysis to the diacetic acid, and decarboxylation to dimethylnaphthalene. The hydrocarbon was an oil, giving a picrate, m. p. 138°. As 1 : 5-dimethylnaphthalene is a solid, and as the picrates of the 1 : 5- and 1 : 4-dimethylnaphthalenes have closely similar melting points, this evidence was inconclusive.

However, supposing the major product of the bischloromethylation of naphthalene to be the 1 : 5-derivative, we decided to attempt the synthesis of *s*-hexahydropyrene by condensing bischloromethylnaphthalene with ethyl malonate, followed by hydrolysis, decarboxylation, ring-closure and reduction. While this work was in progress, two papers by Lock and Walter (*Ber.*, 1942, 75, 1158; 1944, 77, 286) became available to us, and we found that the main object of our work had already been achieved. In the second paper, these authors state that the bischloromethylnaphthalene, for which they give m. p. 150°, is not the 1 : 5- but the 1 : 4-derivative; no evidence of this was presented. Our work has confirmed this conclusion of Lock and Walter, and we have also isolated the 1 : 5-derivative from the crude bischloromethylnaphthalenes resulting from the chloromethylation both of naphthalene and of 1-chloromethylnaphthalene.

Naphthalene was chloromethylated with boiling aqueous formaldehyde and hydrochloric acid (B.P. 345,146; Lock and Walter, *loc. cit.*). Taking advantage of solubility differences in ether, the crude product was separated into several fractions, from which 1 : 5-bischloromethylnaphthalene (II), m. p. 172°, and 1 : 4-bischloromethylnaphthalene (I), m. p. 150°, were obtained by repeated recrystallisation. The constitution of each product was shown by reduction to the dimethylnaphthalene, which was characterised by the formation of the picrate and *s*-trinitrobenzene complex. The major mixed fraction resulting from the treatment with ether had m. p. 128—130°. That this contained some 1 : 5-bischloromethylnaphthalene was

shown by the isolation, in poor yield, of crystalline 1:5-dimethylnaphthalene after reduction, a result which is in agreement with the work of Anderson and Short (*loc. cit.*). However, that this fraction consisted largely of the 1:4-isomer was shown by its conversion into 1:4-bis-(ω -dicarbethoxyethyl)naphthalene (III) (Lock and Walter, *loc. cit.*). The constitution of this

product was shown by hydrolysis, followed by oxidation with potassium ferricyanide, to naphthalene-1:4-dicarboxylic acid. 1:4-Bischloromethylnaphthalene has also been converted into the corresponding dinitrile. This appears to be the same as the dinitrile described as the 1:5-derivative by Manske and Ledingham (*loc. cit.*), and we therefore believe that these authors were in error in attributing the 1:5-configuration to their products, which should all be described as 1:4-derivatives. To confirm this conclusion we have also prepared naphthalene-1:5-diacetonitrile from pure 1:5-bischloromethylnaphthalene.

The patent literature (D.R.-P. 533,850) describes the preparation of a bischloromethyl-tetralin. We have also prepared this, and have shown that it is 5:8-bischloromethyl-1:2:3:4-tetrahydronaphthalene (IV). Reduction with zinc and hydrochloric acid, or with hydrogen and palladium, gave 5:8-dimethyl-1:2:3:4-tetrahydronaphthalene, which on dehydrogenation with sulphur, or with palladised asbestos, gave 1:4-dimethylnaphthalene, characterised by the formation of the picrate and *s*-trinitrobenzene complex.

EXPERIMENTAL.

Chloromethylation of Naphthalene.—(a) A mixture of naphthalene (80 g.), aqueous formaldehyde (40%; 220 g.), and concentrated hydrochloric acid (220 g.) was boiled under reflux with vigorous stirring for 16 hours, while a current of hydrogen chloride was introduced through a tube leading to the bottom of the flask. After cooling, the aqueous layer was decanted, and the pasty mass triturated with ether (100 c.c.). In one run, this ethereal solution deposited, on standing, 1:4-bischloromethylnaphthalene (30 mg.) as colourless needles from alcohol, m. p. 149–150° (Found: C, 64.1; H, 4.5. Calc. for $C_{12}H_{10}Cl_2$: C, 64.0; H, 4.4%). This compound was later obtained pure in considerable quantity. The ethereal solution, after evaporation, gave 1-chloromethylnaphthalene (43 g.), b. p. 150–152°/13 mm., and crude bischloromethylnaphthalenes, b. p. 180–200°/13 mm., m. p. 128–130°.

The solid obtained after this ether washing was extracted with ether (200 c.c.) in a Soxhlet apparatus. The ether deposited, on cooling, crude bischloromethylnaphthalene (19 g.), m. p. 128–130°. Recrystallisation from alcohol did not raise the m. p., although later work showed that this fraction contained both the 1:4- and the 1:5-isomer. The ethereal filtrate, on evaporation, gave a further impure fraction, m. p. 105–115° (2 g.). The residue (4.0 g.), m. p. 153–159°, remaining in the Soxhlet thimble gave, after several recrystallisations from alcohol, colourless needles of 1:5-bischloromethylnaphthalene, m. p. 171.5–172.5° (Found: C, 64.0; H, 4.4. $C_{12}H_{10}Cl_2$ requires C, 64.0; H, 4.4%).

The above experiment was successfully repeated several times, but in two large scale runs naphthalene (700 g.) gave crude bischloromethylnaphthalene (300 g.) from which no pure 1:5-bischloromethylnaphthalene could be isolated by the above procedure. The crude product was soluble in ether (500 c.c.) and, after several recrystallisations, gave pure 1:4-bischloromethylnaphthalene.

(b) Crude bischloromethylnaphthalene was also obtained by chloromethylating 1-chloromethylnaphthalene (250 g.) in light petroleum (b. p. 100–120°; 300 c.c.) with paraformaldehyde (60 g.) and anhydrous zinc chloride (15 g.), by the method of Anderson and Short, except that the reaction was carried out on the steam-bath, and that hydrogen chloride was passed for 24 hours. The product, obtained in ca. 60% yield, was separated as above, and gave 1.5 g. of pure 1:5-bischloromethylnaphthalene, m. p. 171.5–172.5°.

Reduction of fraction, m. p. 128–130°. A mixture of bischloromethylnaphthalene, m. p. 128–130° (1.2 g.), in a little alcohol, and zinc dust (1.5 g.) was boiled for 1 hour, concentrated hydrochloric acid being added at intervals. After distillation (b. p. 60–65°/0.2 mm.), the product was dissolved in 50% acetone. After standing, the crystalline product which separated (75 mg.) was recrystallised from alcohol, and had m. p. 79.5–80.5°. The orange-red picrate had m. p. 138–139°, and the product isolated was therefore 1:5-dimethylnaphthalene, in agreement with Anderson and Short (*loc. cit.*).

Reduction of 1:4-bischloromethylnaphthalene. 1:4-Bischloromethylnaphthalene (m. p. 149°) was reduced in about 50% yield as above. The product formed a colourless oil, b. p. 132–134°/15 mm. (Found: C, 92.4; H, 7.4. Calc. for $C_{12}H_{12}$: C, 92.3; H, 7.7%). The picrate crystallised from methanol in long orange-red needles, m. p. 142–144° (Found: N, 10.9. Calc. for $C_{12}H_{12}O_4N_2$: N, 10.9%). Kloetzel (*J. Amer. Chem. Soc.*, 1940, **62**, 1708) gives m. p. 143–144°. The *s*-trinitrobenzene complex formed yellow needles, from methanol, m. p. 164–166° (Found: N, 11.6. Calc. for $C_{12}H_{12}O_6N_6$: N, 11.4%). Kloetzel (*loc. cit.*) gives m. p. 165–166°. The reduction product was therefore 1:4-dimethylnaphthalene.

The reduction was also carried out in almost quantitative yield by hydrogenation over palladium black in acetone.

Reduction of 1:5-bischloromethylnaphthalene. 1:5-Bischloromethylnaphthalene (m. p. 172°) was reduced as above with zinc and hydrochloric acid. The 1:5-dimethylnaphthalene, which crystallised

from the reaction mixture, was purified by sublimation at $100^{\circ}/13$ mm., and formed colourless lustrous plates, m. p. $80-81^{\circ}$ (Found : C, 92.2; H, 7.6. Calc. for $C_{15}H_{11}$: C, 92.3; H, 7.7%); Butz (*J. Amer. Chem. Soc.*, 1940, **62**, 2557) gives m. p. 80° , and Anderson and Short (*loc. cit.*) give m. p. $80-80.5^{\circ}$. The picrate formed orange-red needles, from methanol, m. p. $138-139^{\circ}$ (Found : N, 10.9. Calc. for $C_{15}H_{11}O_7N_3$: N, 10.9%); Butz (*loc. cit.*) gives m. p. 137° , and Anderson and Short (*loc. cit.*) give m. p. $138-139^{\circ}$. The *s*-trinitrobenzene complex formed yellow needles, from alcohol, m. p. $158-159^{\circ}$ (Found : N, 11.3. $C_{15}H_{11}O_9N_3$ requires N, 11.4%).

1 : 4-Bis-(ω -dicarboxyethyl)naphthalene.—Ethyl malonate (200 g.) was added to a solution of sodium (18 g.) in alcohol (300 c.c.). After cooling, bischloromethylnaphthalene, m. p. $128-130^{\circ}$ (23 g.), suspended in alcohol (200 c.c.) was added. After 10 hours' refluxing the product was worked up in the usual way. The ester (20 g.) formed colourless needles, from alcohol, m. p. $68.5-69^{\circ}$ (Found : C, 65.8; H, 6.7. Calc. for $C_{26}H_{22}O_8$: C, 66.1; H, 6.8%); Lock and Walter (*loc. cit.*) give m. p. 66.5° . A solution of this ester (20 g.) in methanol (75 c.c.), water (150 c.c.), and sodium hydroxide (36 g.) was refluxed for 8 hours, a further quantity (10 g.) of sodium hydroxide being added after the first 4 hours. The bismalonic acid (9 g.) was recrystallised from water. It decomposed at about 140° with evolution of gas, finally melting at $255-256^{\circ}$.

Proof of constitution. A solution of this acid (2 g.), potassium ferricyanide (300 g.), potassium hydroxide (43 g.), and water (1 l.) was heated at $70-80^{\circ}$, with stirring, for 24 hours. A further quantity (80 g.) of potassium ferricyanide and potassium hydroxide (14 g.) in a little water was then added, and the heating continued for 8 hours. After cooling, the filtered solution was acidified, and the precipitate collected, suspended in water, and extracted with ether. The ethereal extract on evaporation gave an acid, m. p. $309-310^{\circ}$ (75 mg.). The methyl ester had m. p. $63-64^{\circ}$. These constants are in agreement with the published figures for naphthalene-1 : 4-dicarboxylic acid.

Naphthalene-1 : 4-diacetonitrile.—The following procedure was found superior to that of Manske and Ledingham (*loc. cit.*). A mixture of 1 : 4-bischloromethylnaphthalene, m. p. $148-150^{\circ}$ (0.5 g.), potassium cyanide (0.5 g.) in a little water, and alcohol (30 c.c.) was boiled under reflux for 2 hours. After addition of water, the naphthalene-1 : 4-diacetonitrile (0.3 g.) was recrystallised from alcohol, and formed colourless prisms, m. p. $140-142^{\circ}$ (Found : C, 81.7; H, 4.75. Calc. for $C_{14}H_{10}N_2$: C, 81.55; H, 4.85%). The same compound was obtained following a similar experiment with crude bischloromethylnaphthalene, m. p. $128-130^{\circ}$. This compound is evidently identical with the derivative, m. p. 140° , described by Manske and Ledingham (*loc. cit.*) as the 1 : 5-derivative.

Naphthalene-1 : 5-diacetonitrile.—This was prepared as above, using 1 : 5-bischloromethylnaphthalene. The naphthalene-1 : 5-diacetonitrile formed colourless small needles, m. p. $188-189^{\circ}$ (Found : C, 81.4; H, 4.6. $C_{14}H_{10}N_2$ requires C, 81.55; H, 4.85%).

Chloromethylation of Tetralin.—Freshly distilled tetralin (90 g.), concentrated hydrochloric acid (210 g.), and aqueous formaldehyde (40%; 220 g.) were boiled under reflux, with stirring, for 48 hours, while hydrogen chloride was passed in. The cooled mixture was extracted with ether, and the ethereal solution dried and evaporated. The oily residue partly crystallised. The solid was collected, washed with a little ether, and recrystallised from alcohol. **5 : 8-Bischloromethyl-1 : 2 : 3 : 4-tetrahydronaphthalene** (10 g.) was obtained as colourless lustrous needles, m. p. $117-118^{\circ}$ (Found : C, 62.9; H, 6.0. $C_{12}H_{14}Cl_2$ requires C, 62.9; H, 6.1%). The oil was collected in two fractions, b. p. $150-180^{\circ}/17$ mm. (85 g.), and $180-195^{\circ}/13$ mm. (12 g.). The latter deposited a further quantity (2 g.) of bischloromethyltetralin on standing.

5 : 8-Dimethyl-1 : 2 : 3 : 4-tetrahydronaphthalene. **5 : 8-Bischloromethyl-1 : 2 : 3 : 4-tetrahydronaphthalene** (4.5 g.) was reduced with zinc and hydrochloric acid, in alcohol, as described for the bischloromethylnaphthalenes. The **5 : 8-dimethyl-1 : 2 : 3 : 4-tetrahydronaphthalene** (0.8 g.) was obtained as a colourless oil, b. p. $125^{\circ}/14$ mm. (Found : C, 90.1; H, 10.25. Calc. for $C_{14}H_{18}$: C, 90.0; H, 10.0%) (cf. Barnett and Sanders, *J.*, 1933, 434). The reduction was also carried out, in almost quantitative yield, by hydrogenation over palladium black in acetone.

Dehydrogenation of 5 : 8-dimethyl-1 : 2 : 3 : 4-tetrahydronaphthalene. The above dimethyltetrahydronaphthalene (0.5 g.) was dehydrogenated with sulphur (0.3 g.) at $230-250^{\circ}$ for 2 hours. The product was converted into the picrate (0.6 g.), which formed orange-red needles, m. p. $142-143^{\circ}$, alone, or mixed with the picrate of 1 : 4-dimethylnaphthalene. The *s*-trinitrobenzene complex formed yellow needles, m. p. $163-165^{\circ}$, alone, or mixed with the *s*-trinitrobenzene complex of 1 : 4-dimethylnaphthalene. The same results were obtained when the dehydrogenation was carried out with palladised asbestos at 240° for 5 hours.

We thank Mr. J. M. L. Cameron for the microanalyses. One of us (G. M. B.) has been working with the aid of an Imperial Chemical Industries Research Fellowship.

UNIVERSITY OF GLASGOW.

[Received, January 1st, 1947.]

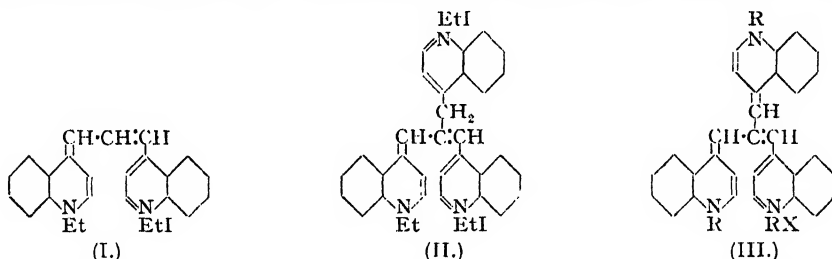

271. Some Trinuclear Cyanine Dyes. Part I. The Synthesis of Neocyanines.

By FRANCES M. HAMER, RUSSELL J. RATHBONE, and BARBARA S. WINTON.

Neocyanine is a trinuclear cyanine dye, which had been obtained as a by-product by the action of alkali on a lepidinium salt in the presence of iodoform or ethyl orthoformate, and for which three formulæ had been proposed. That which represents it as being both a substituted trimethincyanine and a substituted pentamethincyanine has now been established by synthesis. Analogous dyes having three similar heterocyclic nuclei other than 4-linked quinoline have also

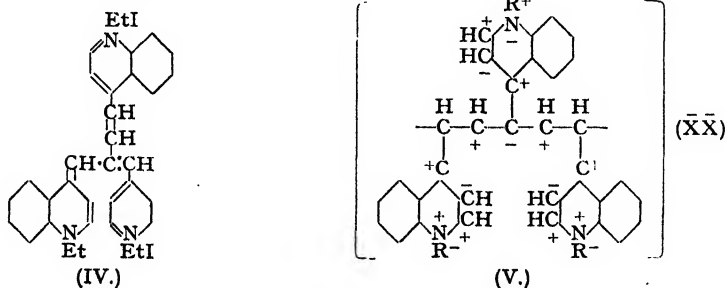

been synthesised. The necessary branched-chain intermediates, consisting of *N*-alkyldihydro-derivatives of heterocyclic bases, with a dianilisoisopropylidene group in the reactive position, were prepared from the corresponding methylene bases or their anilomethyl derivatives, by heating with ethylisoformanilide and zinc chloride. Their condensation with heterocyclic quaternary ammonium salts, having a reactive methyl group, resulted in neocyanines identical with those obtained empirically, when such existed. The absorption maxima of the trinuclear dyes have been compared with those of the related tri- and penta-methincyanines.

NEOCYANINE, a new sensitiser for the infra-red, was announced by Dundon, Schoen, and Briggs (*J. Opt. Soc. Amer.*, 1926, **12**, 397) as sensitising more powerfully beyond 8000 Å. than any dye previously reported. They said it had been isolated by H. T. Clarke as a less soluble by-product in the preparation of 4:4'-carbocyanine but did not specify his method. At that time, the normal method for preparing a 4:4'-carbocyanine, apart from the synthesis by Mills and Braunholtz which established its constitution (I) (*J.*, 1923, **123**, 2804), consisted in treating a lepidinium salt with alkali in the presence of formaldehyde or chloroform (Adams and Haller, *J. Amer. Chem. Soc.*, 1920, **42**, 2661). Only in 1928 did the acceptance of a British patent disclose that neocyanine had been produced in a 4:4'-carbocyanine preparation in which iodoform had been used instead (Kodak Ltd., B.P. 292,274/1927); the corresponding American patent did not appear for another three years (Clarke, U.S.P. 1,804,674/1931). Meanwhile one of us (Hamer, *J.*, 1927, 2796), in describing a general method for the preparation of carbocyanines by condensing a quaternary, heterocyclic ammonium salt having a reactive methyl group, with ethyl orthoformate in the presence of pyridine, recorded that the 4:4'-carbocyanine was accompanied by a by-product, identical with neocyanine. Soon afterwards, in preparing a neocyanine from each of three lepidinium salts, a modified method gave 36—41% yields. Analyses led to the conclusion that the neocyanine molecule had been formed from three molecules of lepidine alkyl halide, with elimination of hydrogen halide, and that either one or two

additional carbon atoms had entered the molecule. Based on the former supposition, the first neocyanine formula (II), showing it as a β-substituted 4:4'-carbocyanine (I), was proposed (Hamer, *J.*, 1928, 1472).

To dyes prepared from lepidinium and from quinaldinium salts, with carbon tetrachloride and alkali, Ogata and Tamura assigned formulæ such as (III) (*Bull. Inst. Phys. Chem. Res. Japan*, 1934, **13**, 475), but Ogata subsequently disclaimed these (*ibid.*, p. 491) and adopted formulæ of type (II) for dyes of the neocyanine class, which he prepared from alkiodides of several heterocyclic bases with orthoformic ester or diphenylformamidine in the presence of various condensing agents (*Proc. Imp. Acad. Tokyo*, 1932, **8**, 503; *ibid.*, 1933, **9**, 602; *Bull. Inst. Phys. Chem. Res. Japan*, 1934, **13**, 497).

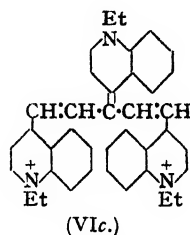

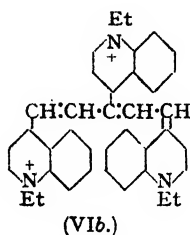

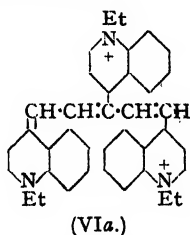

In 1931 Brooker described the neocyanines of the thiazole series and in addition to a formula of type (II) suggested an alternative (IV) with a different carbon chain (B.P. 408,273/1931).

Since alkali would be likely to convert (II) into (III), whereas (IV) had the advantage of explaining the stability of the neocyanines to alkali, formula (IV) was preferred to (II) (Brooker, Hamer, and Mees, *Phot. J.*, 1933, 57, 258; *J. Opt. Soc. Amer.*, 1933, 23, 216).

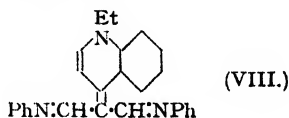

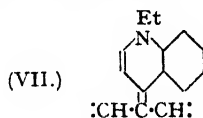

In 1935 W. König, in a theoretical paper on the chemistry of sensitizers, expressed his disbelief in formula (II) and said that he regarded neocyanine as a pentamethincyanine of formula (V). He pointed out that whereas (V) has 4:4'-linkings, other analogous substances with 2:2'-linkings are also possible, and he gave a general formula for those (*Z. wiss. Phot.*, 1935, 34, 15).

The essential feature of König's formula was the symmetrical attachment of the three heterocyclic nuclei to an unbranched-pentamethin chain, and concurrence with this view of the structure was at once expressed (Hamer, *Chem. and Ind.*, 1935, 13, 640) on the ground that it accorded with a reasonable manner of formation of the dye; neocyanine could be regarded as arising from the condensation of the methyl group of lepidine ethiodide with two molecules of ethyl orthoformate and the subsequent condensation of the resulting intermediate with two more molecules of lepidine ethiodide.

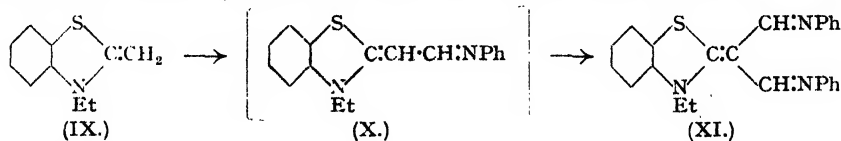

On the modern views a neocyanine kation of this structure would have its two units of positive charge distributed over the three basic groups. It cannot therefore be represented by a single structural formula, but would be regarded as a resonance hybrid of the three canonical structures (VIa, b, and c).

These formulæ, in particular (VIc), suggest the possibility of a rational synthesis of neocyanine from a suitable intermediate containing the grouping (VII), and the dianilo-compound (VIII) seemed most likely to fulfil this purpose. We have succeeded in preparing a number of dianils of this type and have found that with their aid the synthesis of the corresponding neocyanines can in fact be readily accomplished.

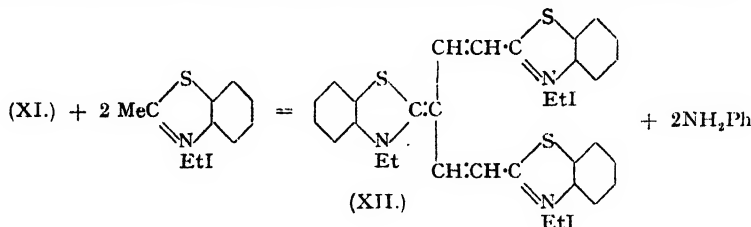

The synthesis was first carried out in the benzthiazole series, with the aid of ethylisoformanilide which, as Knott has recently shown (*J.*, 1946, 120), condenses even more readily than diphenylformamidine (I.C.I. Ltd., Piggott, and Rodd, B.P. 344,409/1929) with pyridinium salts having a reactive methyl group. As a starting point we employed, instead of a quaternary salt, the methylene base 3-ethyl-2-methylenebenzthiazoline (IX) (Hamer, Rathbone, and Winton, this vol., p. 954). Heated with ethylisoformanilide in the presence of zinc chloride, this yielded a zinc chloride complex of the base (XI), from which the base itself could be isolated

by appropriate treatment with alkali. The presumed intermediate (X) had already been described by Brooker and White, who obtained it by the action of alkali on 2-β-anilino vinyl-benzthiazole ethiodide (U.S.P. 2,298,732/1942), and we found that it also could be condensed with ethylisoformanilide to yield (XI). It is safe to assume that the methin group attached to the ring is attacked, rather than the more remote methin group, since the former is in the well-known reactive position. We should have liked to have obtained direct proof of this assumption and therefore prepared the α- and β-methyl derivatives of (X) (Hamer, Rathbone,

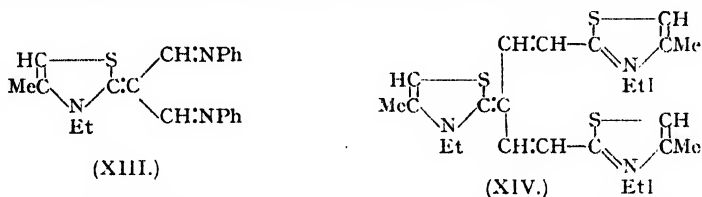

and Winton, *loc. cit.*), hoping to be able to condense the β -methyl derivative with ethylisoformanilide, but the attempt, as also that with the α -methyl derivative, was unsuccessful.

The final stage in the synthesis was readily effected. The dianilo-base (XI), heated for a few minutes with 2-methylbenzthiazole ethiodide, either in pyridine solution or with sodium acetate and acetic anhydride, gave in excellent yield a neocyanine (XII), identical with that obtained by Ogata's method (*Proc. Imp. Acad. Tokyo*, 1933, 9, 602; *Bull. Inst. Phys. Chem. Res. Japan*, 1934, 13, 497) from a 2-methylbenzthiazolium salt and ethyl orthoformate.

In the thiazole series we prepared the *dianilo-base* (XIII) from 4-methyl-3-ethyl-2-anilo-ethylidene- Δ^4 -thiazoline, condensed it with 2 : 4-dimethylthiazole etho-*p*-toluenesulphonate in pyridine, and isolated the dye as iodide (XIV), which was identical with that obtained by the empirical method from the same quaternary salt with ethyl orthoformate and pyridine (B.P. 408,273/1931).

Neocyanine itself was synthesised in a similar manner. The necessary *dianil* (VIII) was prepared by condensation of the methylene base from lepidine etho-*p*-toluenesulphonate with ethylisoformanilide and this, heated with lepidine ethiodide, acetic anhydride and sodium acetate,

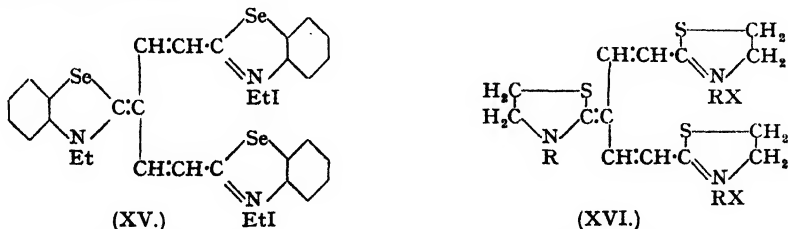

gave in 20% yield a product identical with the neocyanine obtained from lepidine ethiodide and ethyl orthoformate in the presence of pyridine (Hamer, *J.*, 1927, 2796; cf. *idem*, *J.*, 1928, 1472).

The synthesis of neocyanines in this manner may be taken as proof of the correctness of the structure now assigned to them.

In addition to the three dianilo-bases, (VIII), (XI), and (XIII), the following representatives of this class have been prepared: 5-chloro-3-ethyl-2-dianiloisopropylidenbenzthiazoline, 3-ethyl-2-dianiloisopropylidene-6 : 7-benzbenzthiazoline, 3-ethyl-2-dianiloisopropylidenbenzselanazoline, 3-methyl-2-dianiloisopropylidenethiazolidine, 3-ethyl-2-dianiloisopropylidenethiazolidine, 1-ethyl-2-dianiloisopropylidene-1 : 2-dihydroquinoline, 3-ethyl-2-dianiloisopropylidenbenzoxazoline.

From the dianils, new neocyanines were prepared, namely the *dichloride* corresponding with the di-iodide (XII), *analogues* of (XII) having, respectively, three 6 : 7-benzbenzthiazole and three 5-chlorobenzthiazole nuclei, its *seleno-analogue* (XV), and two Δ^2 -thiazoline analogues (XVI). It will naturally be understood that each of these formulæ is to be taken as the representative of a set of resonating structures.

The absorption curves of methyl-alcoholic solutions of the trinuclear dyes were plotted. They were well-defined and rather narrow, with sometimes an inflexion on the short wave-length side. Since the neocyanines might be regarded as combining the structural characters of the

tri- and penta-methincyanines, we give in the following table the wave-lengths of the absorption maxima of seven neocyanines and for comparison those of the corresponding tri- and penta-methincyanines. Certain abbreviations, obvious in conjunction with the text, have been used. Each previously recorded absorption maximum is marked with a bibliographic reference, the unmarked ones being those of compounds described in the present paper. Some of the parent cyanines were prepared for the sake of this comparison. With each of the seven neocyanines, the absorption maximum lies between that of the unsubstituted trimethincyanine and pentamethincyanine, as recorded already for one such dye (Hamer, *Chem. and Ind.*, 1935, 13, 640). The bathochromic shifts on passing from trimethincyanine to neocyanine vary from 375 to 710 Å. and those on passing from neocyanine to pentamethincyanine vary from 350 to 520 Å. Other comparisons may also be made. For instance, replacement of the three 4-linked quinoline nuclei of neocyanine by three benzthiazole nuclei caused a hypsochromic shift of 1735 Å. Replacement of three benzthiazole nuclei by three methylthiazole nuclei caused a hypsochromic shift of 140 Å., whilst their replacement by three 5-chlorobenzthiazole, three 6:7-benzbenzthiazole, or three benzselenazole nuclei caused bathochromic shifts of 90, 335, and 185 Å., respectively.

The new dyes comprised photographic sensitisers and desensitisers.

Neocyanine.	Abs. max., Å.	Trimethin- cyanine.	Abs. max., Å.	Pentamethin- cyanine.	Abs. max., Å.	Bathochromic shifts : trimethin- to neo- cyanine.	neo- to pentamethin- cyanine.

Nomenclature.—Some years ago we first adopted the practice of publishing the systematic names for the cyanines in addition to other names (Fisher and Hamer, *J.*, 1937, 907) or, as the structures became more complex, exclusively (Beilenson and Hamer, *J.*, 1942, 98). Thus whilst (I) may be described as 1:1'-diethyl-4:4'-carbocyanine iodide (Mills and Braunholtz, *J.*, 1923, 123, 2804), its systematic name is [bis-4-(1-ethylquinoline)]trimethincyanine iodide. This nomenclature presupposes only a knowledge of the fundamental structure of a cyanine dye; each ring is denoted by its usual description and numbering, and the positions of linking are indicated. In extending the systematic nomenclature to the present trinuclear cyanines, it is apparent that neocyanine itself might be named either as a substituted trimethincyanine or as a substituted pentamethincyanine. In introducing one fresh convention, that a trinuclear dye is named as a derivative of that parent cyanine having the shorter chain, of course we do not intend to imply that it actually is a derivative of that cyanine rather than of the one having the longer chain. A second parenthesis is introduced to comprise the third nucleus and here the numbers which indicate the position of linking and the positions of substituents are each

followed by a dash, whilst the Greek letters show the positions of attachment of the chain linking the third nucleus. Thus neocyanine is called [bis-4-(1-ethylquinoline)][$\alpha\beta'$ -dimethin-4'-(1'-ethylquinoline)]trimethincyanine di-iodide.

EXPERIMENTAL.

3-Ethyl-2-dianiloisopropylidenebenzthiazoline (XI).—3-Ethyl-2-methylenebenzthiazoline (33.17 g.; 1 mol.), zinc chloride powder (76.5 g.; 3 mols.), and ethylisoformanilide (277 c.c.; 10 mols.) were heated together at 175–180° for 2½ hours, with mechanical stirring. Acetone (700 c.c.) was added, and the mixture heated until all lumps had gone. After cooling, the zinc chloride complex was filtered off and washed with acetone. It was ground with, and stirred into, water (750 c.c.). It was filtered off, washed with methyl alcohol, boiled out twice with that solvent (1000 c.c., 200 c.c.), and washed twice with hot methyl alcohol (50 c.c. \times 2).

For converting the complex (54.2 g.) into base, it was ground with water (10 c.c. per g.) and with 40% sodium hydroxide solution (20 c.c. per g.) and the suspension was shaken with acetone (100 c.c. per g.). The acetone extract was filtered and the aqueous residue was further extracted twice with acetone (10 c.c. per g. \times 2). The extracts were dried over stick sodium hydroxide for a period of days, then filtered, and the acetone was distilled off under a vacuum (in six lots) and the concentrate (volume about 15 c.c. \times 6) cooled. The base crystallised and was filtered off and washed with methyl alcohol until the washings were no longer brown. The yield was 28% (19.76 g.). In recrystallising from methyl alcohol (110 c.c. per g.), the time of heating was kept to a minimum and the yield was 21% (15.36 g.). (After drying in a vacuum desiccator, it was analysed by the method of Carius, which method was used throughout this work for sulphur and halogen determinations.) (Found: S, 7.9. Calculated for $C_{24}H_{21}N_3S$: S, 8.35%). The yellow crystals had m. p. 127°, becoming orange at about 110°. The broad absorption curve had its maximum at 4020 Å. and an inflexion at 3500 Å. The base was photographically inert.

In the second method of preparation, 3-ethyl-2-aniloethylidenebenzthiazoline (X) (47 g.; 1 mol.), zinc chloride (94 g.; 4.1 mols.), and ethylisoformanilide (250 g.; 10 mols.) were heated together at 160–185° for 1 hour. After partial cooling, acetone (1000 c.c.) was added; refluxing was applied, in order to break up a hard lump. When cold, the solid was filtered off, washed with acetone, and ground with water (107 g. obtained). It was thrice boiled out with methyl alcohol (2350 c.c. \times 3) (8.01 g., 0.09 g., and 0.16 g., respectively, crystallised from the filtrates). When a test portion of the solid from the first boiling out was heated with a 2-methylbenzthiazolium salt in pyridine, it gave a red colour, whilst a test portion of the second or third, when similarly treated, gave a blue. The boiling out with methyl alcohol halved the weight of zinc chloride complex. It was converted into free base as before and gave a 17% yield (11 g.), and after recrystallisation from methyl alcohol 10% (6.46 g.). Its m. p. was the same as that of the sample prepared by the first method, and that of the mixture was identical.

5-Chloro-3-ethyl-2-dianiloisopropylidenebenzthiazoline.—5-Chloro-3-ethyl-2-methylenebenzthiazoline (24 g.; 1 mol.), zinc chloride (47 g.; 3 mols.), and ethylisoformanilide (170 g.; 10 mols.) were heated together at 190°, with mechanical stirring, for 1½ hours. After partial cooling, acetone (1000 c.c.) was added and the solid was filtered off, ground with water (28 g. left), and boiled out with methyl alcohol (500 c.c. \times 4). The filtrates varied from purple to pale pink, but a negligible amount of solid (total, 0.1 g.) separated from them. The yellow zinc chloride complex (24.12 g.) was ground with 40% sodium hydroxide solution (400 c.c.) and water (200 c.c.) and extracted with acetone (5000 c.c.). The extract was dried with stick sodium hydroxide, the solvent distilled off under a vacuum, and the concentrate cooled, giving a 16% yield of crude base (7.83 g.). A sample was recrystallised from pyridine (5 c.c. per g.; yield 12%) (Found, after drying in a vacuum at 60–80°, which method of drying was employed throughout this work except where otherwise stated: Cl, 8.7. Calculated for $C_{24}H_{20}N_3ClS$: Cl, 8.5%). The yellow crystals had m. p. 182–184°. The absorption curve had its maximum at 4100 Å. and tailed off very gradually on the short wave-length side. Towards a gelatino-chloride photographic emulsion the substance exerted slight sensitisation as far as 4700 Å.

3-Ethyl-2-dianiloisopropylidene-6:7-benzbenzthiazoline.—To 3-ethyl-2-methylene-6:7-benzbenzthiazoline (11.43 g.) was added ethylisoformanilide; zinc chloride powder was stirred in, and the mixture heated. It was stirred by hand, in order to break up the lumps of zinc chloride, until the oil-bath temperature reached 80°. Mechanical stirring was then applied and the temperature was raised to 175–180° and held there for an hour. After cooling, the hard reaction product was treated with acetone (250 c.c.), being heated and stirred at intervals for a few hours in order to break up the lumps. The solid was filtered off, washed with acetone, ground with water, and then boiled out four times with methyl alcohol (450 c.c. \times 4). The residual complex (9.52 g.) was ground with water (10 c.c. per g.), added to acetone (100 c.c. per g.), and shaken with 40% sodium hydroxide solution (20 c.c. per g.) until all solid had disappeared. The acetone layer was filtered, and the aqueous part further twice extracted with acetone (200 c.c., 100 c.c.). The extracts were dried over stick sodium hydroxide for 2 days. The filtrate was then concentrated under a vacuum until almost all the acetone had been removed and only a little aqueous liquid was left. The solid which separated on cooling was filtered off and obtained, after washing with acetone, in 21% yield (4.49 g.). It was recrystallised from methyl alcohol (4000 c.c.), the time of heating being reduced to the very minimum. The yield was 9% (1.86 g.) but in a recrystallisation where boiling with mechanical stirring went on for 7 minutes the yield was only half that (Found: S, 7.2. Calculated for $C_{28}H_{23}N_3S$: S, 7.4%). The dull yellow crystals melted at about 173° with previous darkening and shrinking. The absorption maximum was at 3890 Å. and the base did not sensitise a gelatino-chloride photographic emulsion.

3-Ethyl-2-dianiloisopropylidenebenzselazoline.—3-Ethyl-2-aniloethylidenebenzselazoline (20 g.; 1 mol.), ethylisoformanilide (44 g.; 5 mols.), and zinc chloride (18 g.; 2.2 mols.) were heated together at 160–170° for 30 minutes. The product was treated with water, and the solid was next thoroughly ground and washed with acetone and boiled out with methyl alcohol (1400 c.c.). The zinc chloride

complex (11.5 g.) was converted into base, by grinding to a paste with water and shaking with 40% sodium hydroxide solution (100 c.c.) and acetone (500 c.c.). The filtered acetone extract was dried with stick sodium hydroxide, then concentrated considerably. The base was filtered off, washed with spirit, and obtained in 14% yield (3.8 g.). On recrystallisation from methyl alcohol (80 c.c. per g.), the yield fell to 7% (Found : N, 9.9. $C_{24}H_{21}N_3Se$ requires N, 9.75%). The bright yellow crystals had m. p. 140° (decomp.). The absorption curve had a maximum at 4070 Å. and an inflexion at 3550 Å. The substance did not sensitise a gelatino-chloride photographic emulsion.

In a second method of preparation, 3-ethyl-2-methylenebenzelenazoline (22.4 g.; 1 mol.), ethylisoformanilide (75 c.c.; 5 mols.) and zinc chloride (41 g.; 3 mols.) were heated together at 150–170° for 2 hours. The washed product was boiled out with methyl alcohol (1000 c.c.), leaving a residue of zinc chloride complex (5.62 g.). The yield of crude base was 10%, falling to 7% on recrystallisation from methyl alcohol. M. p. and mixed m. p. showed its identity with the sample prepared by the first method. A by-product (5.25 g.) which separated from the methyl-alcoholic extract of crude zinc chloride complex was identified as follows as a zinc chloride complex of 3-ethyl-2-aniloethylidenbenzelenazoline. It was treated with 40% sodium hydroxide solution (40 c.c.) and acetone (100 c.c.); on pouring the concentrated acetone extract into water, a base (4.11 g.) resulted, and after recrystallisation from light petroleum (b. p. 80–100°), consisted of a 20% yield (2.83 g.) of what was proved to be 3-ethyl-2-aniloethylidenbenzelenazoline, by comparison with a genuine specimen.

It is noteworthy that we were unable to prepare the dianilo-base by the action of ethylisoformanilide and zinc chloride on the zinc chloride complex of 3-ethyl-2-aniloethylidenbenzelenazoline, which tallies with the fact that it could not be thus prepared from the hydrochloride either, *i.e.*, from 2-β-anilinoethylidenbenzelenazole ethochloride.

4-Methyl-3-ethyl-2-dianiloisopropylidene-Δ⁴-thiazoline (XIII).—4-Methyl-3-ethyl-2-aniloethyliden-Δ⁴-thiazoline (48.8 g.; 1 mol.), ethylisoformanilide (152 g.; 5 mols.), and zinc chloride (80 g.; 3 mols.) were heated together at 150–170° for 2 hours. The crude zinc chloride complex was washed with acetone, treated with water, and boiled out with methyl alcohol (3200 c.c.) (64.8 g. left). It was then shaken vigorously at room temperature with 40% sodium hydroxide solution (560 c.c.) and acetone (3200 c.c.). The acetone extract was concentrated to small bulk and the base precipitated by addition of ice-water (31.6 g. obtained). On recrystallisation from light petroleum (b. p. 80–100°; 35 c.c. per g.), a 35% yield (23.9 g.) of golden-yellow crystals was obtained (Found : S, 9.05. $C_{21}H_{21}N_3S$ requires S, 9.25%). M. p. 111° (decomp.). The absorption maximum was at 3475 Å. The base was inert towards a gelatino-chloride photographic emulsion.

3-Methyl-2-dianiloisopropylidenethiazolidine.—3-Methyl-2-aniloethylidenethiazolidine (10.20 g.; 1 mol.), ethylisoformanilide (70 c.c.; 10 mols.), and zinc chloride (19.13 g.; 3 mols.) were heated together at 175–180° for 1½ hours. The warm viscous mass was treated with acetone (150 c.c.). The solid was filtered off, treated with water (300 c.c.), and boiled out four times with methyl alcohol (125 c.c. × 4) (12.85 g. of zinc chloride complex left).

In order to liberate the free base, the zinc chloride complex (8 g.) was ground with acetone (120 c.c.), and the mixture cooled with ice and stirred mechanically. An ice-cold solution of sodium (2 g.) in absolute alcohol (120 c.c.) was run in, and stirring with cooling was applied for 10 minutes; when the sodium ethoxide solution was first added, the liquid became bright yellow. The solid, which apparently consisted of zinc oxide and sodium zincate, was filtered off and washed with acetone (16 c.c.). On pouring the filtrate and washings into ice-cold water (500 c.c.), the base was precipitated as a yellow solid, being obtained in 36% yield (3.33 g.). Rapid recrystallisation from methyl alcohol (25 c.c. per g.) gave a 30% yield, but when boiling and mechanical stirring were applied for 5 minutes, decomposition took place, so that the yield was only 4% (Found : S, 9.95. $C_{19}H_{19}N_3S$ requires S, 10.0%). Recrystallisation from light petroleum (b. p. 80–100°) was less precarious and gave an 18% yield. The lemon-yellow crystals had m. p. 127°. The absorption maximum was at 3720 Å. The base was photographically inert.

3-Ethyl-2-dianiloisopropylidenethiazolidine.—The zinc chloride complex (66 g.) was prepared similarly from 3-ethyl-2-aniloethylidenethiazolidine (90.6 g.) and was converted (in 20 g. lots) into the free base, of which the yield was 33% (43 g.). After recrystallisation from light petroleum (b. p. 80–100°; 120 c.c. per g.), the yield was 22% (Found, after drying in a vacuum at 50° : S, 9.6. $C_{20}H_{21}N_3S$ requires S, 9.55%). The bright yellow crystals had m. p. 104°. The absorption maximum of the broad curve was at 3530 Å. The base was photographically inert in a gelatino-chloride emulsion.

1-Ethyl-4-dianiloisopropylidene-1 : 4-dihydroquinoline (VIII).—1-Ethyl-4-methylene-1 : 4-dihydroquinoline (10.44 g.; 1 mol.) was treated with ethylisoformanilide (90.5 c.c.; 10 mols.) and zinc chloride powder (25 g.; 3 mols.) and the mixture was heated in an oil-bath and stirred by hand until the temperature reached 80° and the large lumps had been broken up. Mechanical stirring was then applied and the mixture was heated at 175–185° for 1½ hours. Whilst still warm, the reaction mixture was treated with acetone (150 c.c.), whereupon hardening occurred. After intermittent heating, the dark syrupy liquid was poured off and the hard residue heated with another equal amount of acetone, and finally with yet another, which left no residue. All the dark mixtures were filtered after cooling and the residual solid was further washed with acetone, and with water (600 c.c.). The solid was boiled out thrice with methyl alcohol (400 c.c. × 3). The first filtrate was almost black, the second dark brown, the third amber, and the residual solid (12.74 g.) a clean, bright orange.

In order to obtain the base, the zinc chloride complex (2 g.) was ground with acetone (30 c.c.), and the suspension cooled with ice and treated with an ice-cold solution of sodium (0.45 g.) in absolute alcohol (30 c.c.). The solid was crushed until orange streaks were no longer visible : the liquid became dark yellow. The grey residue was filtered off and washed with a cooled alcohol-acetone mixture : the filtrates were poured into ice-cold water (60 c.c.). Before the bright yellow solid could be filtered off it had become brown. It was washed with ice-cold water and dried in the air and finally in a vacuum desiccator. The yield of base was 34% (1.24 g.). 1 G. was twice extracted with hot light petroleum (b. p. 40–60°; 20 c.c. × 2), each extract being filtered into a tube cooled with ice. The yield of recrystallised product was only 3% (Found, after drying in a vacuum desiccator : N, 11.0. $C_{24}H_{21}N_3$

requires N, 11.15%). When heated, the light brown powder began to shrink at 90°; decomposition was gradual and the substance was quite black by 154° but without any definite m. p. The absorption maximum was at 4785 Å., with another maximum at 4020. The base sensitised a gelatino-chloride photographic emulsion weakly up to 5400 Å., with the maximum at 4950.

1-Ethyl-2-dianiloisopropylidene-1 : 2-dihydroquinoline.—1-Ethyl-2-methylene-1 : 2-dihydroquinoline (10.14 g.) was heated with ethylisoformanilide and zinc chloride as in the previous preparation. The warm product was treated with acetone (120 c.c.) and left to stand, with occasional warming. The suspension was poured off from the hard residue, which was similarly treated with a second portion of acetone (120 c.c.) and later with a third (120 c.c.). After cooling, the extracts were filtered, giving a black, treacly filtrate. The residual product was washed with acetone, ground with water (400 c.c.), and thrice boiled out with methyl alcohol (750 c.c. \times 3). The residue of zinc chloride complex was a dull orange (7.31 g. obtained).

Its conversion into base was carried out as in the preceding preparation. The yield of washed, dried base was 7% (0.82 g. from two 2 g. lots of complex). It was a dirty yellow when first precipitated but finally a dark green. On recrystallising as quickly as possible from light petroleum (b. p. 80–100°; 60 c.c. per g.), the yield dropped to 1% (Found, after drying in a vacuum desiccator: N, 10.85. $C_{24}H_{21}N_3$ requires N, 11.15%). The light brown powder had no definite m. p.; shrinking began at about 95° and considerable decomposition had occurred by 105°. The broad absorption curve had its maximum at 4100 Å. On a gelatino-chloride emulsion the base conferred traces of sensitivity up to 5200 Å.

3-Ethyl-2-dianiloisopropylidenebenzoxazoline.—3-Ethyl-2-aniloethylidenebenzoxazoline (106 g.; 1 mol.), ethylisoformanilide (300 c.c.; 5 mols.) and zinc chloride (168 g.; 3 mols.) were heated together at 150–160° for 1 hour. The reaction mixture was heated with acetone, and the solid boiled out with methyl alcohol (1600 c.c.). The resultant zinc chloride complex (45 g.) was warmed and shaken with 20% sodium hydroxide solution (7.5 c.c. per g.) and acetone (65 c.c. per g.). After concentration, the acetone extract was precipitated with aqueous ammonium chloride solution, and the crude base recrystallised from methyl alcohol (100 c.c. per g.) (18 g. obtained). As a sample left some ash on heating, the base was purified by suspending it in spirit (20 c.c. per g.) and acidifying with concentrated hydrochloric acid (4 c.c. per g.). The filtered solution was treated with ammonia and the precipitated base was obtained in 6% yield (8.6 g.). On recrystallisation from methyl alcohol (700 c.c.), the yield dropped to 4% (5.3 g.) and on a second recrystallisation (from 450 c.c.) to 3% (Found: N, 11.6. $C_{24}H_{21}ON_3$ requires N, 11.45%). The bright yellow crystals had m. p. 210° (decomp.). The absorption maximum was at 3755 Å. The compound was photographically inert.

[Bis-2-(3-ethylbenzthiazole)][aβ'-dimethin-2'-(3'-ethylbenzthiazole)]trimethincyanine Di-iodide (XII).—3-Ethyl-2-dianiloisopropylidenebenzthiazoline (XI) (0.19 g.; 1 mol.) was ground with 2-methylbenzthiazole ethiodide (0.31 g.; 2 mols.) and the mixture heated with pyridine (2 c.c.) at 130–140° for 5 minutes. A blue colour rapidly developed and solid crystallised. It was filtered off when cold and washed with pyridine and with ether, being obtained in 90% yield (0.36 g.). After recrystallisation from methyl alcohol (100 c.c. per g.) it was obtained in 74% yield (0.28 g.) (Found: I, 31.55. $C_{32}H_{31}N_5S_3$ requires I, 31.45%). The dark green crystals had m. p. 243° (decomp.). The absorption maximum was at 6015 Å. with an inflexion to the curve at 5550. The dye caused weak photographic sensitisation, extending to 7000, with its maximum at 6450 Å.

In a preparation in which the pyridine was replaced by anhydrous sodium acetate (0.33 g.; 8 mols.) and acetic anhydride (2 c.c.), the yield of crude product, after washing with acetic anhydride, ether, and water, was 65%, and after recrystallisation from methyl alcohol it was 55%.

Ogata (*Bull. Inst. Phys. Chem. Res. Japan*, 1934, 13, 497; cf. *idem*, *Proc. Imp. Acad. Tokyo*, 1933, 9, 602) heated together 2-methylbenzthiazole ethiodide, orthoformic ester, and succinic acid at 170°, and claimed a 15% yield of thiocarbocyanine and a 1% yield of more soluble neocyanine, with no indication that a troublesome purification is necessary. In repeating the preparation, our best result was obtained by heating together 2-methylbenzthiazole etho *p*-toluenesulphonate (3 g.; 3 mols.), succinic acid (2.72 g.; 8 mols.), and ethyl orthoformate (3 c.c.; 3.2 mols.) at 180–190° for 10 minutes. After cooling, the liquid was poured off, and the residual tar washed with absolute ether (25 c.c.). It was then heated with a solution of crystalline sodium carbonate (6.6 g.; 8 mols.) in water (10 c.c.), so as to remove any succinic acid. To convert the dyes into iodides, potassium iodide (3 g.) was added and the green solid was filtered off. In addition to a dye giving a pink and one giving a blue solution, other matter was present. After two washings with water (10 c.c. \times 2), the residue (1.18 g.) was thrice boiled out with methyl alcohol (10 c.c. \times 3). The blue dyes from the first two fractions were put together (0.33 + 0.13 g.), but the bluish-pink dye (0.10 g.) from the third was rejected. The residue was recrystallised from absolute alcohol (50 c.c.) and gave the pink thiocarbocyanine (0.20 g.). On precipitating the combined methyl-alcoholic filtrates with absolute ether (150 c.c.), a further yield of the blue dye was obtained (0.06 g., making the total 0.52 g.). The dye giving a blue solution was twice boiled out with absolute alcohol (50 c.c. per g. \times 2), and was then recrystallised from methyl alcohol (50 c.c. per g.), in which the neocyanine was considerably more soluble than in absolute alcohol. The final yield of purified thiocarbocyanine was 17% (0.15 g.) and of purified neocyanine 9% (0.09 g.) (Found: I, 31.9. $C_{32}H_{31}N_5S_3$ requires I, 31.45%). Ogata correlated his nitrogen determination with the formula $C_{31}H_{31}N_5S_3$ and gave m. p. 256° (decomp.). The present specimen was found to have the same m. p., mixed m. p., and absorption as the synthetic one.

[Bis-2-(3-ethylbenzthiazole)][aβ'-dimethin-2'-(3'-ethylbenzthiazole)]trimethincyanine Dichloride.—The preceding di-iodide (0.88 g.) was converted into the dichloride by boiling its solution in spirit (176 c.c.) with freshly precipitated silver chloride and taking the filtered solution down to dryness. The dichloride (0.52 g.; 76% yield) was given two recrystallisations from ethyl alcohol (3 c.c. per g.) and ethyl acetate (18 c.c. per g.) and thus obtained in 49% yield (Found: Cl, 10.6; S, 14.4. $C_{32}H_{31}N_5Cl_2S_3$ requires Cl, 10.4; S, 14.35%). Its green crystals melted at about 200° (decomp.). It was insoluble in anhydrous ether or in ethyl acetate but readily soluble in methyl or ethyl alcohol and in water.

[Bis-2-(3-ethyl-6 : 7-benzbenzthiazole)][aβ'-dimethin-2'-(3'-ethyl-6' : 7'-benzbenzthiazole)]trimethincyanine Di-iodide.—3-Ethyl-2-dianiloisopropylidene-6 : 7-benzbenzthiazoline (0.87 g.; 1 mol.) and 2-methyl-6 : 7-

benzbenzthiazole ethiodide (1.42 g.; 2 mols.) were ground together, treated with pyridine (16 c.c.), and heated with mechanical stirring at 130–140° for 10 minutes. The washed solid was recrystallised from methyl alcohol (600 c.c.) and gave a 56% yield (1.07 g.). A second recrystallisation from spirit (630 c.c. per g.) gave a 36% yield. Filtration of the recrystallised dye was extraordinarily slow (Found: I, 26.2. $C_{44}H_{31}N_3I_2S_2$ requires I, 26.5%). The dark bronze substance had m. p. 216° (decomp.). The absorption maximum was at 6350 Å. with an inflexion to the curve at 5900 Å. The dye did not sensitise but caused some depression of the normal sensitivity of the plate.

[Bis-2-(5-chloro-3-ethylbenzthiazole)][$\alpha\beta'$ -dimethin-2'-(5'-chloro-3'-ethylbenzthiazole)]trimethincyanine Di-iodide. — 5-Chloro-3-ethyl-2-dianiloisopropylidenebenzthiazoline (1.56 g.; 1 mol.), 5-chloro-2-methylbenzthiazole ethiodide (2.55 g.; 2 mols.), anhydrous sodium acetate (1.23 g.; 4 mols.), and acetic anhydride (10 c.c.) were heated together at 150° for 10 minutes. The washed dye (2.93 g.; 86% yield) was recrystallised from methyl alcohol (320 c.c. per g.), after which the yield was 51% (Found: 3 Cl + 2I, 39.35. $C_{32}H_{28}N_3Cl_3I_2S_2$ requires 3Cl + 2I, 39.55%). The green crystals had m. p. 240° (decomp.). The absorption maximum was at 6105 Å. with an inflexion to the curve at 5700 Å. The compound did not sensitise and strongly depressed the blue sensitivity of a photographic emulsion. A pure product was not obtained in earlier experiments where the condensing agent was pyridine.

[Bis-2-(3-ethylbenzelenazole)][$\alpha\beta'$ -dimethin-2'-(3'-ethylbenzelenazole)]trimethincyanine Di-iodide (XV). — 3-Ethyl-2-dianiloisopropylidenebenzelenazoline (0.66 g.; 1 mol.), 2-methylbenzelenazole ethiodide (1.06 g.; 2 mols.), and pyridine (6 c.c.) were heated and stirred together at 135–140° for 5 minutes. On recrystallising the washed dye (0.93 g. obtained; 65% yield) from methyl alcohol (195 c.c. per g.), the yield was 56% (0.80 g.) (Found: I, 26.85. $C_{32}H_{31}N_3I_2Se_2$ requires I, 26.75%). The dull green crystals had m. p. 226° (decomp.). The absorption maximum was at 6200 Å., with an inflexion to the curve at about 5740 Å. The compound had a strong desensitising effect on a photographic plate.

[Bis-2-(4-methyl-3-ethylthiazole)][$\alpha\beta'$ -dimethin-2'-(4'-methyl-3'-ethylthiazole)]trimethincyanine Di-iodide (XIV). — 4-Methyl-3-ethyl-2-dianiloisopropylidene- Δ^4 -thiazoline (XIII) (0.69 g.; 1 mol.), 2:4-dimethylthiazole etho-*p*-toluenesulphonate (1.25 g.; 2 mols.), and pyridine (5 c.c.) were heated together at 130° for 40 minutes. The pyridine was removed under reduced pressure, and the residue dissolved in hot spirit and poured into a hot aqueous solution of potassium iodide (2.2 g.; 8 mols.). The dye (1.04 g.; 74% yield) was recrystallised from absolute alcohol (20 c.c.) and thus obtained in 59% yield (0.82 g.) as dark blue crystals (Found: I, 36.25. Calc. for $C_{22}H_{31}N_3I_2S_2$: I, 36.3%; it had m. p. 206° (decomp.), which was also the m. p. of the mixture of this synthetic specimen with that of the one prepared by the empirical method given below. The substance had a narrow absorption curve with its maximum at 5875 Å. It sensitised to 7100 Å., the maximum lying at 6300. In these respects it was identical with the sample prepared by the following method.

By the empirical method, 2:4-dimethylthiazole etho-*p*-toluenesulphonate (31 g.), ethyl orthoformate, and pyridine were boiled together for 5 hours (Kodak Ltd. and Brooker, B.P. 408,273/1931). The product (6.23 g.) obtained by concentration in a vacuum, followed by precipitation with potassium iodide, was boiled out four times with methyl alcohol (15 c.c. \times 3, 25 c.c.). The fraction which crystallised from the first two extracts was combined with a second crop which resulted on concentration of the first three filtrates (total 5.2 g.). This was given a second fractional crystallisation from absolute alcohol (20 c.c., 25 c.c.) and methyl alcohol (15 c.c.) but this time there was no residue and the neocyanine crystallised in 18% yield (3.97 g.) (Found: I, 36.2%). In the first fractional crystallisation, the less soluble residue (0.46 g.) was combined with the dye which crystallised from the last two extracts (0.47 g.) and was recrystallised from methyl alcohol (100 c.c.), being obtained in 3% yield (0.6 g.) (Found: I, 30.3. Calc. for $C_{11}H_{21}N_3I_2S_2$: I, 30.2%). This is bis-2-(4-methyl-3-ethylthiazole)trimethincyanine iodide, identical with that prepared by Fisher and Hamer (J., 1930, 2502).

[Bis-2-(3-methyl- Δ^2 -thiazoline)][$\alpha\beta'$ -dimethin-2'-(3'-methyl- Δ^2 -thiazoline)]trimethincyanine Di-iodide (XVI; R = Me, X = I). — 3-Methyl-2-dianiloisopropylideneethiazolidine (0.64 g.; 1 mol.), 2-methyl- Δ^2 -thiazoline methiodide (1.07 g.; 2.2 mols.), and pyridine (8 c.c.) were heated together at 130–140° for 2 minutes. The washed dye (0.83 g.; 67% yield) was recrystallised from methyl alcohol (25 c.c.). The yield was 53% (0.65 g.) and after a second recrystallisation from methyl alcohol (40 c.c. per g.) it was 42% (Found: I, 40.95. $C_{17}H_{22}N_3I_2S_2$ requires I, 40.85%). When the purplish-red crystals were heated they began to shrink at about 115° and had largely melted and decomposed by 125° but there was no definite m. p. The absorption maximum was at 5065 Å. The dye sensitised a gelatino-bromide photographic emulsion up to 5900 Å.

[Bis-2-(3-ethyl- Δ^2 -thiazoline)][$\alpha\beta'$ -dimethin-2'-(3'-ethyl- Δ^2 -thiazoline)]trimethincyanine Diperchlorate (XVI; R = Et, X = ClO₄). — 3-Ethyl-2-dianiloisopropylideneethiazolidine (1.02 g.; 1 mol.), 2-methyl- Δ^2 -thiazoline ethiodide, and pyridine were heated together at 130–140° for 5 minutes. The gum, precipitated by absolute ether, was dissolved in hot spirit (30 c.c.) and treated with a hot solution of sodium perchlorate (1.68 g.; 4 mols.) in water (30 c.c.). The crude perchlorate (1.59 g.) was boiled out with and recrystallised from methyl alcohol (15 c.c., 225 c.c.), the product being obtained in 51% yield (0.93 g.) (Found: Cl, 11.7. $C_{30}H_{31}O_4N_3Cl_2S_2$ requires Cl, 11.65%). The brick-red crystals had m. p. 230° (decomp.). The absorption maximum was at 5060 Å. In a gelatino-bromide photographic emulsion the compound produced extra-sensitivity up to 5700 Å.

[Bis-4-(1-ethylquinoline)][$\alpha\beta'$ -dimethin-4'-(1'-ethylquinoline)]trimethincyanine Di-iodide. — Crude 1-ethyl-4-dianiloisopropylidene-1:4-dihydroquinoline (VIII) (0.75 g.; 1 mol.), lepidine ethiodide (1.20 g.; 2 mols.), and anhydrous sodium acetate (1.31 g.; 8 mols.) were ground together, treated with acetic anhydride (8 c.c.), and heated at 135–140° for 10 minutes. Brassy crystals of dye began to separate when the temperature reached 110°. The solid was filtered off, washed with acetic anhydride and with ether, ground with water (10 c.c.), washed with methyl alcohol, and boiled out with it three times (20 c.c. \times 3). The first fraction was rejected but the dye which crystallised from the second and third (0.01 g.) was put with the undissolved residue (0.41 g.) making a 27% yield (0.42 g.). On recrystallisation from methyl alcohol (1000 c.c. per g.) the yield was 20% (0.32 g.) (Found: I, 32.3. Calc. for $C_{38}H_{31}N_3I_2$: I, 32.15%). When samples of the original neocyanine ethiodide (Hamer, J., 1928, 1472), of the present synthetic dye, and of their mixture were heated, all melted simultaneously at 280° (decomp.).

We failed to isolate the dye when heating with pyridine took the place of heating with sodium acetate and acetic anhydride, but in another experiment 1-ethyl-4-dianiloisopropylidene-1 : 4-dihydroquinoline (0.19 g.; 1 mol.) and excess of lepidine ethiodide (0.45 g.; 3 mols.) were ground together, treated with ice-cold pyridine (2 c.c.), and left in the cold for six days, with occasional stirring. The crystals were filtered off and well washed; the residue (0.12 g.) was twice boiled out with methyl alcohol (15 c.c., 25 c.c.), and the product which crystallised (0.01 g.) added to what remained (0.02 g.), making up a 7% yield. After recrystallisation from methyl alcohol (30 c.c.), the yield of the characteristic brassy crystals was 2% (0.01 g.).

Bis-2-(5-chloro-3-ethylbenzthiazole)pentamethincyanine Iodide.—5-Chloro-2-methylbenzthiazole ethiodide (1.97 g.; 2 mols.) and β -anilinoacraldehyde anil hydrochloride (0.75 g.; 1 mol.) in boiling absolute alcohol (20 c.c.) were treated with a solution of sodium (0.14 g.; 2 atoms) in absolute alcohol (5 c.c.). The mixture was boiled and stirred for 3 minutes, during which time the solids dissolved and a green dye separated. After three recrystallisations of the washed dye (1.35 g.; 80% yield) from methyl alcohol (2600 c.c., 3900 c.c., and 5000 c.c. per g.) the yield was 38% (Found: 2Cl + I, 33.55. $C_{22}H_{21}N_2Cl_2IS_2$ requires 2Cl + I, 33.7%). The bluish-green crystals had m. p. 298° (decomp.). The absorption maximum was at 6560 Å. The dye sensitised a gelatino-bromide photographic emulsion from 6500—7400 Å., with a maximum at 7000 Å. This preparation was carried out by Dr. V. P. Pittman, whom we thank.

Bis-2-(4-methyl-3-ethylthiazole)pentamethincyanine Iodide.—2 : 4-Dimethylthiazole etho-*p*-toluenesulphonate (12.52 g.; 2 mols.), β -ethoxyacraldehyde diethyl acetal (3.84 g.; 1.1 mols.), and triethylamine (5.6 c.c.; 2 mols.) in pyridine (40 c.c.) were boiled and stirred together for 7 minutes. Ether precipitated a sticky solid which was dissolved in hot spirit and treated with a solution of potassium iodide (13 g.; 4 mols.) in hot water. The crude dye (2.3 g.) was boiled out with and recrystallised from absolute ethyl alcohol (15 c.c., 100 c.c.), being obtained in 21% yield (1.92 g.) (Found: I, 28.3. $C_{17}H_{23}N_2IS_2$ requires I, 28.45%). The steely bluish-green crystals had m. p. 214° (decomp.). The absorption curve had its maximum at 6370 Å. and an inflexion at 6050 Å. It sensitised from 6500—6900 Å. with the maximum at 6800 Å.

Bis-2-(3-ethyl- Δ^2 -thiazoline)pentamethincyanine Iodide.—A mixture of 2-methyl- Δ^2 -thiazoline ethiodide (3.98 g.; 2 mols.), β -anilinoacraldehyde anil hydrochloride (2 g.; 1 mol.), anhydrous potassium carbonate (5.36 g.; 5 mols.; 180-mesh), and ethyl alcohol (10 c.c.) was boiled for 4 minutes. The washed solid (1.71 g.) was recrystallised from methyl alcohol (10 c.c.) and obtained in 27% yield (0.88 g.). After a second recrystallisation from methyl alcohol (10 c.c.), the yield was 24% (0.77 g.) (Found: I, 30.2. $C_{18}H_{23}N_2IS_2$ requires I, 30.05%). The steely crystals had m. p. 231° (decomp.). The absorption maximum was at 5450 Å. The dye sensitised a gelatino-bromide photographic emulsion, the maximum lying at 5700 Å.

We are indebted to Miss M. D. Gauntlett for the absorption measurements and to Drs. B. H. Carroll and E. B. Knott for the sensitising tests.

272. The Galactomannan of the Lucerne Seed.

By E. L. HIRST, J. K. N. JONES, and WINIFRED O. WALDER.

The mucilaginous polysaccharide in the lucerne seed has been shown to consist of a galactomannan containing galactose and mannose in the approximate ratio of 2 to 1. Hydrolysis of the methylated polysaccharide gave a mixture of sugars among which 2 : 3 : 4 : 6-tetramethyl *d*-galactose, 2 : 4 : 6-trimethyl *d*-galactose, and 3 : 4-dimethyl *d*-mannose were detected. The general type of structure present in the polysaccharides is discussed on the basis of this evidence.

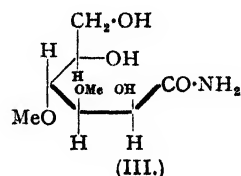

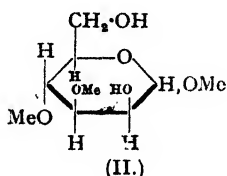

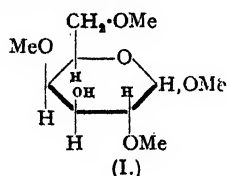

POLYSACCHARIDES other than cellulose are of common occurrence in the cell walls of many plants. They are, in general, insoluble in water but form solutions in dilute sodium hydroxide from which they may be precipitated by the addition of alcohol. Investigation of the hemicelluloses from cell walls, with special reference to the endosperm of ungerminated seeds, has revealed the presence of a number of different polysaccharides. Amongst these are the galactomannans which occur in the endosperm of the seeds of *Phoenix dactylifera*, *Elæis guineensis*, *Cocos nucifera*, *Coffea arabia* (Schulze, Steiger, and Maxwell, *Z. physiol. Chem.*, 1890, **14**, 227), and lucerne seed (May and Schulze, *Z. Biol.*, 1936, **97**, 201; Wise and Appling, *Ind. Eng. Chem. Anal.*, 1944, **16**, 28). Galactomannans have also been shown to occur in the seeds of the Fenugreek (Daoud, *Biochem. J.*, 1932, **26**, 255) and in the Carob bean (Spada, *Atte. Soc. Nat. Mat. Modena*, 1939, **70**, 20). It appears that these polysaccharides may function as reserve material in the seed and are utilised by the seed during germination (Schulze, *Landw. Jahrb.*, 1894, **23**, 1; *Ber. deut. bot. Ges.*, 1896, **14**, 66). In view of these observations and since some of the galactomannans have physical properties closely resembling those of the mucilages it was considered of interest to determine the mode of linkage of the sugars in the polysaccharide molecule.

The polysaccharide was isolated from lucerne seeds by the procedure given by Schulze

(*loc. cit.*). It was a white powder which did not reduce Fehling's solution and gave aqueous solutions of comparatively high viscosity. It underwent hydrolysis with boiling *N*-sulphuric acid at a rate indicating the presence of pyranose sugar residues in the molecule, and a quantitative determination of the sugars proved that *D*-mannose and *D*-galactose were present in the approximate ratio of 1 to 2. No other sugar could be detected.

The fully methylated galactomannan was obtained by reaction with sodium hydroxide and methyl sulphate followed by further treatment of the thallium hydroxide complex of the partially methylated derivative with methyl iodide.

The methylated polysaccharide, which was essentially homogeneous, was resistant to methyl-alcoholic hydrogen chloride. Hydrolysis was effected by use of a mixture of hydrochloric acid and glacial acetic acid which has been shown by Bell (*Biochem. J.*, 1935, 29, 2031) to be efficacious in the hydrolysis of resistant polysaccharides. The products were isolated as the methylglycosides, and on distillation fractions containing the following sugars were obtained: (1) 2:3:4:6-tetramethyl methyl-*D*-galactoside, identified after hydrolysis and formation of the characteristic crystalline anilide of tetramethyl *D*-galactose; (2) 2:4:6-trimethyl *D*-methylgalactoside (I), identified after hydrolysis as the crystalline sugar and as its crystalline anilide; and (3) 3:4-dimethyl *D*-methylmannoside (II), isolated after hydrolysis and oxidation as the crystalline 3:4-dimethyl *D*-mannonamide (III). Intermediate fractions were also obtained.

The isolation of these sugars proves that the galactomannan is not a mixture of a galactan and a mannan. This follows since a polysaccharide built of solely glycosidically linked mannose residues, some of which are present in a form having three points of linkage with other mannose residues, must possess a corresponding number of residues connected to others only by one linkage. The experimental results show clearly that no such mannose end groups are present, and it follows that the mannose residues must be present in a structure containing galactose also. The sugar residues isolated are all in the pyranose form and are substituted on C_4 by a methoxyl group. The isolation of a large amount of 2:3:4:6-tetramethyl *D*-galactose (*ca.* 30%) proves that the polysaccharide is of the branched-chain type and that half the galactose residues are terminal groupings. Unfortunately, the exact ratios of 2:4:6-trimethyl *D*-galactose and 3:4-dimethyl *D*-mannose could not be accurately determined in these experiments since some of the intermediate fractions which had not been fully examined were lost by enemy action. Nevertheless, an inspection of the methoxyl figures indicates that the relative molecular proportions of 2:3:4:6-tetramethyl methyl-*D*-galactoside, trimethyl methylhexoside, and dimethyl methylhexoside are 1:1:1. At least one-third of the dimethyl methylhexoside is known to be 3:4-dimethyl methylmannoside, and at least one-third of the trimethyl methylhexoside is 2:4:6-trimethyl methylgalactoside. A further investigation will be necessary in order to determine whether or not other sugars are present amongst the products of hydrolysis. In the meantime it is clear that half the galactose residues are attached in the form $\text{Gal} \dots$ and therefore are end groups. Another set of galactose residues is present in the form $\dots 3\text{Gal} \dots$, linked through positions 1 and 3, and at least one-third of the mannose residues occur as $\dots \frac{6\text{M}}{2} \dots$, linked through positions 1, 2, and 6.

It will be observed that the 1:3 galactose linkage so common in polysaccharides containing galactose, and the 1:6 and 1:2 mannose linkages occurring in damson gum, cherry gum (Hirst, *J.*, 1942, 70), and yeast mannan (Haworth, Hirst, and Isherwood, *J.*, 1937, 784; Haworth, Hart, and Peat, *J.*, 1941, 833), also occur in this galactomannan.

EXPERIMENTAL.

(All temperatures recorded for distillations are bath temperatures).

Lucerne seeds (500 g.) were finely ground and heated at 100° for 8 hours, with continuous stirring, with 10% potassium hydroxide solution (4 l.) until a jelly-like mass was formed and no more ammonia was evolved. The alkaline solution was then poured with stirring into alcohol (8 l.), and the dark solid which separated was washed with alcohol by decantation and filtered off. The precipitate was

purified by reprecipitation from water with alcohol. Insoluble cell-wall material was then removed by heating the solid with potassium hydroxide solution (4 l.) for 3 hours, cooling, and centrifuging. The insoluble residues were extracted repeatedly until the extracts gave no precipitate on addition of alcohol. The combined extracts were then poured into alcohol (4 vols.) and the precipitate was filtered off and further purified by reprecipitation from acidified aqueous solution (hydrochloric acid) with alcohol.

Traces of starch were removed from the polysaccharide by the action of "taka-diastase" (0.05%) at 37° for 12 hours. Further purification was achieved by precipitation of the copper complex by the addition of copper sulphate solution to a hot alkaline solution of the crude polysaccharide until no further material was precipitated. The copper complex was washed well with hot water and filtered off. The complex was decomposed by grinding it with alcohol containing hydrochloric acid, and the regenerated polysaccharide was ground and washed with alcohol until free from copper and chloride ions. Finally, the product was purified by dissolving it in water and precipitating it from the aqueous solution with alcohol, and dried in vacuum. Yield, 10 g. of a white powder, which dissolved in water to form viscous non-reducing solutions; $[\alpha]_D^{20} + 89^\circ$ (Found: furfuraldehyde, 2; uronic acid, nil; N, nil; mannose, determined as the phenylhydrazone after hydrolysis with *N*-sulphuric acid at 95° for 2½ hours, 29.6; galactose, determined as the phenylmethylhydrazone after the same treatment, 58%; equiv. by titration with 0.1*N*-sodium hydroxide, 4540).

Methylation of the Polysaccharide.—The pure polysaccharide (25 g.) was dissolved in water (300 c.c.) and 30% sodium hydroxide (400 c.c.), and methylated with methyl sulphate (200 c.c.) added in portions (30 c.c.) at 20 minute intervals. The methylation was carried out in an atmosphere of nitrogen and with the usual precautions. After 24 hours the cooled solution was partly neutralised with dilute sulphuric acid and concentrated under reduced pressure. The residue was then re-methylated using the conditions described above. Two repetitions of this process gave a crude methylated product (isolated in the usual manner) which was freed from sodium sulphate and other salts by dialysis. Yield, 15.5 g. (Found: OMe, 34.0%). To complete the methylation the product was dissolved in ethyl alcohol (100 c.c.) and benzene (100 c.c.), and a solution of thallium ethoxide (1.7*N*, 100 c.c.) in benzene added. Solvent was removed under reduced pressure and the residual solid finely powdered (150 mesh) and boiled under reflux with methyl iodide (150 c.c.) for 30 hours. Excess of methyl iodide was boiled off and the residual solid extracted exhaustively with acetone. Concentration of the extracts gave a residue of partially methylated galactomannan (15 g.) (Found: OMe, 36.2%). This methylation process with thallium ethoxide and methyl iodide was repeated (see above), and the isolated product (13 g.) methylated with silver oxide (10 g.) and methyl iodide (30 c.c.). Repetition of this process gave a product (13 g.) (Found: OMe, 43.5%) isolated in the usual manner.

Fractionation of the Methylated Polysaccharide.—The methylated polysaccharide (10.1 g.) was fractionally precipitated from chloroform by the addition of light petroleum (b. p. 40–60°) giving: Fraction I (2.1 g.), a white solid, $[\alpha]_D^{20} + 72^\circ$ (c. 1.0 in chloroform) (Found: OMe, 43.4%; furfuraldehyde, nil); Fraction II (6.0 g.), a white solid, $[\alpha]_D^{20} + 71^\circ$ (c. 1.1 in chloroform) (Found: OMe, 43.2%; furfuraldehyde, nil); Fraction III (0.9 g.), a white solid, $[\alpha]_D^{20} + 69^\circ$ (c. 0.9 in chloroform) (Found: OMe, 44.1%; furfuraldehyde, nil); Fraction IV (1.0 g.), a sticky solid.

Hydrolysis of the Methylated Polysaccharide.—Hydrolysis of the methylated material was difficult as the product was relatively stable to boiling methyl-alcoholic hydrogen chloride and to hot *N*-hydrochloric acid. The following procedure was eventually adopted as the most satisfactory technique. The methylated polysaccharide (7.3 g., Fractions I and II) was dissolved in a mixture of glacial acetic acid (50 c.c.), water (25 c.c.), and concentrated hydrochloric acid (25 c.c.), and heated at 100° for 6 hours. Changes in optical rotation were not observable, but preliminary experiments had shown that the hydrolysis was complete at the end of this time. Barium carbonate was added to the cooled solution until a test portion of the solution gave a grey and not a blue colour to Congo-red paper. The solution was then filtered and evaporated to dryness under reduced pressure. The solid residue was then extracted with chloroform, and the extracts were concentrated and boiled with methyl-alcoholic hydrogen chloride (3% w/v) for 12 hours. The cooled solution was then neutralised with silver carbonate and filtered, and the filtrate was concentrated under reduced pressure at 40° to a syrup (6.4 g.) which was fractionally distilled in a vacuum giving: Fraction i (0.86 g.), b. p. 90°/0.001 mm., $n_D^{15} 1.4539$ (Found: OMe, 59.5%); Fraction ii (0.72 g.), b. p. 108°/0.001 mm., $n_D^{15} 1.4522$ (Found: OMe, 61.9%); Fraction iii (0.53 g.), b. p. 110°/0.001 mm., $n_D^{15} 1.4542$ (Found: OMe, 60.0%); Fraction iv (0.57 g.), b. p. 120°/0.01 mm., $n_D^{15} 1.4560$ (Found: OMe, 53.8%); Fraction v (1.40 g.), b. p. 130°/0.001 mm., $n_D^{15} 1.4601$ (Found: OMe, 48.8%); Fraction vi (1.32 g.), b. p. 160°/0.001 mm., $n_D^{15} 1.4680$ (Found: OMe, 41.8%); Fraction vii (0.57 g.), b. p. 170°/0.01 mm., $n_D^{15} 1.4780$ (Found: OMe, 41.9%); residue, 0.43 g.

Hydrolysis of the Fractions.—The first three fractions having very similar methoxyl values were combined (2.1 g.) and hydrolysed by heating with 2*N*-hydrochloric acid at 95° for 3 hours; $[\alpha]_D^{20}$ (initial value not observable), $+ 71^\circ$ (2 hours); $+ 105^\circ$ (3 hours, constant value). The solution was cooled, neutralised with barium carbonate, and filtered, the filtrate concentrated under reduced pressure, and the residue exhaustively extracted with chloroform. Concentration of the extracts gave a syrup (1.9 g.) which was at least 94% 2 : 3 : 4 : 6-tetramethyl *D*-galactose; $[\alpha]_D^{20} + 109^\circ$ (in water) (Found: OMe, 52.2. Calc. for $C_{16}H_{26}O_6$: OMe, 51.8%). The sugar (0.32 g.), on being heated under reflux with aniline (0.1 c.c.) dissolved in alcohol (3 c.c.) for 2½ hours, gave 2 : 3 : 4 : 6-tetramethyl *D*-galactose anilide (0.34 g.), m. p. 189°, not depressed on admixture with an authentic sample. Fraction iv (0.56 g.) was hydrolysed by boiling with 2*N*-hydrochloric acid (25 c.c.) for 3 hours; $[\alpha]_D^{20} + 56^\circ$ (2 hours); $+ 70^\circ$ (3 hours, constant value). The sugar (0.5 g.) was isolated as described above; $[\alpha]_D^{20} + 70^\circ$ (c. 1.0 in water) (Found: OMe, 40.0. Calc. for $C_6H_{12}O_5$: OMe, 41.8%). On standing, the syrup partly crystallised. The crystals were separated by trituration with ether and had m. p. 105°, not depressed on admixture with an authentic specimen of 2 : 3 : 4 : 6-trimethyl *D*-galactose. The syrup (0.4 g.) on boiling with aniline (0.3 g.) in ethyl alcohol (2 c.c.) for 2½ hours gave the anilide of 2 : 3 : 4 : 6-trimethyl *D*-galactose (0.5 g.), m. p. 179°, not depressed on admixture with an authentic specimen. At the most only traces of 2 : 3 : 6-trimethyl *D*-galactose could be present in the syrup, as on standing with cold 5% methyl-alcoholic hydrogen chloride no downward change of rotation was observable; $[\alpha]_D^{20} + 41^\circ$ (initial

value); + 49° (3 hours); + 58° (6 hours). Fraction vii (0.57 g.) was hydrolysed with boiling 2*N*-hydrochloric acid; $[\alpha]_D^{20} + 31^\circ$ (initial value); 0° (3 hours, constant value). The solution was cooled and neutralised with barium carbonate, and the filtrate was evaporated to dryness. The syrup (0.5 g.), isolated in the usual manner, did not crystallise. The absence of any derivative of mannose or galactose with a hydroxyl group on C₄ was indicated by the fact that the syrup (0.03 g.) in methylalcoholic hydrogen chloride (5 c.c.; 5%) showed no change of rotation (+ 10°) in 7 days. The syrup (0.2 g.) was oxidised with bromine water at 45° until non-reducing (7 hours). The cooled solution was neutralised with silver carbonate and filtered, and silver ions were removed with hydrogen sulphide. The filtered solution was concentrated to a syrup (0.15 g.) which did not crystallise. Accordingly, the material was dissolved in liquid ammonia and excess of ammonia allowed to evaporate. The residue crystallised, and by trituration with acetone 3:4-dimethyl *d*-mannonamide, m. p. 139°, not depressed on admixture with an authentic specimen, was isolated. The amide gave a strong positive test for an α -hydroxy-amide by the method of Weerman.

A complete examination of Fractions v and vi was not possible since these fractions were lost by enemy action. They obviously contained some 2:4:6-trimethyl *d*-galactose and 3:4-dimethyl *d*-mannose, but at this stage the presence of other galactose and mannose derivatives cannot be excluded.

We wish to thank Mr. L. J. Breddy for assistance in the preparation of the galactomannan.

273. Preparation and Properties of Allyl Phosphines, Arsines, and Stannanes.

By W. J. JONES, W. C. DAVIES, S. T. BOWDEN, C. EDWARDS, V. E. DAVIS, and L. H. THOMAS.

Phosphines, arsines, and stannanes containing allyl and methylallyl groups have been produced by means of the Grignard reaction, their physical properties have been examined, and characteristic derivatives have been prepared.

No phosphine containing either an allyl or a methylallyl group has hitherto been prepared, though Hofmann (*Phil. Trans.*, 1860, 150, 412) records that he experimented unsuccessfully on the effect of heating phosphorus, zinc, and allyl iodide together in a sealed tube, but phenyl-*p*-tolylmethylallylphosphonium iodide has been obtained by Pope and Gibson (*J.*, 1912, 101, 737; also Radcliffe and Brindley, *J. Soc. Chem. Ind.*, 1923, 42, 66) by the combination of phenyl-*p*-tolylmethylphosphine with allyl iodide, and trisdiphenylallylphosphonium bromide by Worral (*J. Amer. Chem. Soc.*, 1930, 52, 2936) by the union of trisdiphenylphosphine and allyl bromide. Such phosphines have now been prepared by the Grignard method, *triallylphosphine* and *phenyl*-, *p*-tolyl-, *p*-xylyl-, *p*-ethylphenyl-, *p*-isopropylphenyl-, *p*-methoxyphenyl-, *p*-phenoxyphenyl-, and *p*-bromophenyl-diallylphosphine from allylmagnesium bromide, and *tri*- β -methylallylphosphine and *phenyl*-, *p*-tolyl-, *p*-xylyl-, *p*-ethylphenyl-, *p*-isopropylphenyl-, *p*-methoxyphenyl-, and *p*-bromophenyl-di- β -methylallylphosphine from β -methylallylmagnesium bromide.

Triallylsarsine has been obtained by Gryszkiewicz-Trochimowski and Zambrzycki (*Rocz. Chem.*, 1926, 6, 794). *Phenyldiallylsarsine* has now been prepared from allylmagnesium bromide, and *tri*- β -methylallylsarsine and *phenyldi*- β -methylallylsarsine from β -methylallylmagnesium bromide.

Tetra-allyltin has been described by Vijayraghavan (*J. Indian Chem. Soc.*, 1945, 22, 119), and allylstannonic acid and allylpentachlorostannic acid by Lesbre and Glotz (*Compt. rend.*, 1934, 198, 1427). *Triethylallyltin*, *diethyldiallyltin*, *tri*-*n*-butylallyltin and *di*-*n*-butyldiallyltin have been prepared in the present work from allylmagnesium bromide.

In order to secure good yields, it has been found necessary to employ the Grignard reagent in excess over the chlorophosphine, chloroarsine, or chlorostannane, to exclude air rigorously during the preparation, and to distil the product under low pressure. In the reaction, diallyl, *b. p.* 59.5°, or di- β -methylallyl, *b. p.* 113°, is formed as by-product through the coupling action of the Grignard reagent, but the hydrocarbon is easily separated, after the ether, by distillation from the phosphine, arsine, or stannane.

The allylphosphines rapidly oxidise in contact with air. They combine with mercuric chloride to give mercurichlorides of the general formula PR_3HgCl_2 , with benzoquinone to produce pale yellow addition compounds $\text{PR}_3\text{C}_6\text{H}_4\text{O}_2$, with carbon disulphide to yield either intensely red compounds PR_3CS_2 or red colorations in solution, and with methyl iodide to give the methylphosphonium iodides. These methiodides combine with mercuric iodide to

form yellow complex mercuri-iodides $\text{PR}_4\text{I}, \text{HgI}_2$, and with cadmium iodide to give cadmi-iodides $(\text{PR}_4\text{I})_2, \text{CdI}_2$. The allylarsines closely resemble the phosphines chemically, and the allylstannanes also are rapidly attacked by air.

In the absence of air, the allyl-phosphines, -arsines, and -stannanes are thermally stable, being unaffected even on being kept at 250° for an hour. A comparison of the b. p./50 mm. with that of the corresponding *n*-alkyl compound is made in the following table, from which it will be seen that the difference is slight.

Phosphine.	B. p./50 mm.	Phosphine.	B. p./50 mm.
Triallyl	98°	Tri- <i>n</i> -propyl	103°
Phenyldiallyl	160	Phenyldi- <i>n</i> -propyl	159
<i>p</i> -Tolyldiallyl	171	<i>p</i> -Tolyldi- <i>n</i> -propyl	174
<i>p</i> -Xylyldiallyl	179	<i>p</i> -Xylyldi- <i>n</i> -propyl	180
<i>p</i> -Ethylphenyldiallyl	188	<i>p</i> -Ethylphenyldi- <i>n</i> -propyl	181
Tri- β -methylallyl	142	Tri- <i>n</i> -butyl	149
Phenyldi- β -methylallyl	184	Phenyldi- <i>n</i> -butyl	185
<i>p</i> -Tolyldi- β -methylallyl	190	<i>p</i> -Tolyldi- <i>n</i> -butyl	197
<i>p</i> -Xylyldi- β -methylallyl	200	<i>p</i> -Xylyldi- <i>n</i> -butyl	204
<i>p</i> -Ethylphenyldi- β -methylallyl ...	205	<i>p</i> -Ethylphenyldi- <i>n</i> -butyl	209
Arsine.		Arsine.	
Triallyl	111	Tri- <i>n</i> -propyl	110
Phenyldiallyl	171	Phenyldi- <i>n</i> -propyl	165
Tri- β -methylallyl	143	Tri- <i>n</i> -butyl	155
Phenyldi- β -methylallyl	189	Phenyldi- <i>n</i> -butyl	193
Stannane.		Stannane.	
Triethylallyl	112	Triethyl- <i>n</i> -propyl	112

As is shown in the next table, the average difference between the molecular volumes (in c.c.) of an aryldiallylphosphine and its corresponding aryldi- β -methylallylphosphine at 25° is 34.0 c.c., compared with 33.0 c.c. for two CH_2 groups in the higher trialkylphosphines (Jackson, Davies, and Jones, *J.*, 1931, 2109).

Phosphine.	Diallyl.	Di- β -methylallyl.	Diff.
Phenyl	196.2	230.2	34.0
<i>p</i> -Tolyl	211.5	246.5	35.0
<i>p</i> -Xyllyl	227.6	262.0	34.4
<i>p</i> -Ethylphenyl	230.0	263.2	33.2

The Lorenz-Lorentz molecular refractivities, $(n^2 - 1)M/(n^2 + 2)d$, of the allyl phosphines for sodium D light are given in the following table. The calculated values have been obtained by means of the constants given by Eisenlohr (*Z. physikal. Chem.*, 1910, **75**, 605), together with those given for phosphorus by Jones, Davies, and Dyke (*J. Physical Chem.*, 1933, **37**, 594).

$[M_L]_D$.			$[M_L]_D$.

The phosphines, arsines, and stannanes are freely soluble in ether, alcohol, benzene, or carbon tetrachloride, but not in water. The molecular weights, M , of the phosphines have been determined by the cryoscopic method in benzene solution, and found to be normal.

EXPERIMENTAL.

Preparation of the Phosphines.—The necessary dichlorophosphines, phenyl b. p. $221-222^\circ$, *p*-tolyl b. p. $100^\circ/12$ mm., *p*-xyllyl b. p. $133^\circ/16$ mm., *p*-ethylphenyl b. p. $133^\circ/18$ mm., *p*-isopropylphenyl b. p. $132-134^\circ/14$ mm., *p*-methoxyphenyl b. p. $153^\circ/21$ mm., *p*-phenoxyphenyl b. p. $200^\circ/12$ mm., and *p*-bromophenyl b. p. $135-136^\circ/14$ mm., were prepared by the method of Michaelis (*Ber.*, 1879, **12**, 1009; *Annalen*, 1896, **293**, 223) and isolated either by the distillation method of Grüttner and Wiernik (*Ber.*, 1915, **48**, 1475) or by the extraction method of Davies (*J.*, 1935, 463). Allyl bromide,

b. p. 70–71°, was prepared as described in *Org. Synth.*, I, 24. To prepare β -methylallyl bromide, phosphorus tribromide (45 c.c.) was added dropwise with exclusion of moisture during 5 hours with periodic shaking to dried (CaO), freshly-distilled β -methylallyl alcohol (118 c.c.) in dried (KOH), freshly-distilled pyridine (32 c.c.) cooled with ice-salt: the reaction mixture was filtered, and the filtrate on distillation gave β -methylallyl bromide, b. p. 94–95° (85 g.). Both bromides after drying (P_2O_5 or $CaCl_2$) were used immediately, after a fresh distillation, for the preparation of the phosphines.

To 1½ mols. (36.5 g.) of finely divided magnesium a granule of iodine and 100 c.c. of absolute ether, contained in a dried round-bottom flask fitted with a mechanical stirrer, dropping funnel, reflux condenser, siphon tube, and a gas-inlet tube, through which dry hydrogen was passed, there was added, dropwise in the course of about 2 hours so as to maintain a gentle boiling, ½ mol. of allyl bromide (42 c.c.) or of β -methylallyl bromide (51 c.c.) in 285 c.c. of ether (Gilman and McGlumphy, *Bull. Soc. chim.*, 1928, 43, 1322). After an hour's standing, the Grignard solution was siphoned quickly through a glass-wool filter into a second round-bottom flask provided with similar fittings to the first, and, with continuous stirring, passage of hydrogen and external cooling with ice, thereto was added gradually in ether (100 c.c.) 1/12 mol. of phosphorus trichloride (7.1 c.c.) or 1/8 mol. of the aryldichlorophosphine [phenyl (17 c.c.), *p*-tolyl (19 c.c.), *p*-xylyl (21 c.c.), *p*-ethylphenyl (21 c.c.), *p*-isopropylphenyl (22 c.c.), *p*-methoxyphenyl (20 c.c.), *p*-phenoxyphenyl (24 c.c.), or *p*-bromophenyl (19 c.c.)]. After the addition, the mixture was boiled for ½ hour, again cooled to 0°, and then ammonium chloride (50 g.) in water (250 c.c.) was added gradually through the dropping-funnel until all the precipitated magnesium salts had dissolved. The resulting mixture was siphoned under carbon dioxide into a separating funnel, and the ether layer was dried (Na_2SO_4) in a stoppered bottle. The dried solution was distilled in carbon dioxide to remove ether and diallyl or di- β -methylallyl, and the residual phosphine was redistilled in carbon dioxide under low pressure and preserved in sealed glass tubes. All subsequent manipulations of the phosphine were carried out under carbon dioxide.

Triallylphosphine.—This compound was prepared from allylmagnesium bromide and phosphorus trichloride: the liquid (4 g.) had b. p. 69°/13 mm. (Found: C, 70.1; H, 10.0; P, 19.7. $C_9H_{14}P$ requires C, 70.1; H, 9.8; P, 20.1%). Mercuric chloride added to the phosphine in alcohol precipitated the *mercurichloride*, rhomboids, in. p. 135° (Found: Cl, 16.9; P, 7.2. $C_9H_{14}P.HgCl_2$ requires Cl, 16.7; P, 7.3%). This and all the succeeding mercurichlorides, mercuri-iodides and cadmi-iodides were repeatedly recrystallised to constant m. p. from alcohol, except where another solvent is stated.

The phosphine (1 c.c.) in alcohol (20 c.c.) mixed with *p*-benzoquinone (0.4 g.) in alcohol (20 c.c.) produced a red coloration, and after standing, the addition of ether precipitated pale-yellow stellate crystals of *triallylphosphine-p-benzoquinone*, which darkened at 100° and became black at 130° (Found: C, 69.1; H, 7.5. $C_{15}H_{18}O_2P$ requires C, 68.7; H, 7.3%). Excess of carbon disulphide added to the phosphine (2 c.c.) in alcohol (5 c.c.) gave a dark red coloration, and on cooling to 0° *triallylphosphine-carbondisulphide* separated as red needles, m. p. 32.5°, unstable in the air (Found: C, 51.7; H, 6.9. $C_{11}H_{14}PS_2$ requires C, 52.1; H, 6.6%). Mixed in the absence of air, the phosphine and methyl iodide in ether immediately gave a precipitate of *methyltriallylphosphonium iodide*, pearly flakes from alcohol-ether (Found: I, 42.7. $C_{10}H_{14}PI$ requires I, 42.9%).

Phenyldiallylphosphine.—This compound (8 g.) was obtained by the interaction of allylmagnesium bromide and phenyldichlorophosphine and had b. p. 127°/14 mm., d_4^{25} 0.9693, n_D^{25} 1.5670 (Found: C, 75.5; H, 8.1. $C_{12}H_{16}P$ requires C, 75.7; H, 8.0%). It formed the *mercurichloride*, needles, m. p. 123° (Found: Cl, 15.6. $C_{12}H_{16}P.HgCl_2$ requires Cl, 15.4%).

***p*-Tolyldiallylphosphine.**—The phosphine (7 g.) was produced from allylmagnesium bromide and *p*-tolylchlorophosphine and had b. p. 138°/14 mm., d_4^{25} 0.9651, n_D^{25} 1.5545 (Found: C, 75.9; H, 8.9. $C_{13}H_{17}P$ requires C, 76.4; H, 8.4%). It yielded the *mercurichloride*, elongated prisms, m. p. 110.5° (Found: Cl, 14.9. $C_{13}H_{17}P.HgCl_2$ requires Cl, 14.9%).

***p*-Xylyldiallylphosphine.**—The interaction of the allyl Grignard reagent and *p*-xylyldichlorophosphine gave the phosphine (16 g.), which had b. p. 144°/13 mm., d_4^{25} 0.9584, n_D^{25} 1.5540 (Found: C, 76.6; H, 8.8; P, 14.0; M, 223. $C_{14}H_{18}P$ requires C, 77.0; H, 8.8; P, 14.2%; M, 218). The *mercurichloride* crystallised in rhomboids, m. p. 170° (Found: Cl, 14.9; P, 6.3. $C_{14}H_{18}P.HgCl_2$ requires Cl, 14.5; P, 6.3%).

***p*-Ethylphenyldiallylphosphine.**—Obtained from allylmagnesium bromide and *p*-ethylphenyldichlorophosphine, the phosphine (16 g.) had b. p. 145°/10 mm., d_4^{25} 0.9484, n_D^{25} 1.5545 (Found: C, 76.7; H, 9.0. $C_{14}H_{18}P$ requires C, 77.0; H, 8.8%).

***p*-isopropylphenyldiallylphosphine.**—This compound (16 g.) was prepared from allylmagnesium bromide and *p*-isopropylphenyldichlorophosphine and had b. p. 153°/11 mm., d_4^{25} 0.9361, n_D^{25} 1.5435 (Found: C, 77.5; H, 9.1; M, 242. $C_{15}H_{20}P$ requires C, 77.5; H, 9.1%; M, 232). It yielded the *mercurichloride*, m. p. 47°, from glacial acetic acid (Found: Cl, 14.6. $C_{15}H_{20}P.HgCl_2$ requires Cl, 14.1%).

***p*-Methoxyphenyldiallylphosphine.**—This phosphine (12 g.), produced from allylmagnesium bromide and *p*-methoxyphenyldichlorophosphine, had b. p. 162°/15 mm., d_4^{25} 1.0189, n_D^{25} 1.5705 (Found: C, 70.6; H, 8.1. $C_{13}H_{18}OP$ requires C, 70.9; H, 7.8%). Its *mercurichloride* separated in prisms, m. p. 131° (Found: Cl, 14.8. $C_{13}H_{18}OP.HgCl_2$ requires Cl, 14.4%).

***p*-Phenoxyphenyldiallylphosphine.**—Obtained by the action of the allyl Grignard reagent on *p*-phenoxyphenyldichlorophosphine, this phosphine (12 g.) had b. p. 238°/15 mm., d_4^{25} 1.0847, n_D^{25} 1.6040 (Found: C, 76.2; H, 7.1; P, 10.9; M, 278. $C_{15}H_{18}OP$ requires C, 76.6; H, 6.8; P, 11.0%; M, 282). The *mercurichloride*, difficultly soluble in alcohol and ether, became black at 210° (Found: Cl, 13.2. $C_{15}H_{18}OP.HgCl_2$ requires Cl, 12.8%).

***p*-Bromophenyldiallylphosphine.**—The allyl Grignard reagent and *p*-bromophenyldichlorophosphine gave the phosphine (15 g.), b. p. 186°/37 mm., d_4^{25} 1.2783 (Found: C, 53.1; H, 5.5; P, 11.4; M, 272. $C_{11}H_{11}BrP$ requires C, 53.5; H, 5.2; P, 11.5%; M, 269). The *mercurichloride* crystallised in needles, m. p. 108° (Found: P, 5.7. $C_{11}H_{11}BrP.HgCl_2$ requires P, 5.7%).

Tri- β -methylallylphosphine.—This tertiary phosphine (5 g.) was prepared through the interaction of β -methylallylmagnesium bromide and phosphorus trichloride and had b. p. 112°/15 mm. (Found:

C, 73.1; H, 11.0; P, 15.4; M, 196. $C_{15}H_{21}P$ requires C, 73.4; H, 10.8; P, 15.8%; M, 196. It immediately oxidised in the air to form the *oxide*, needles, m. p. 132°, from ether (Found: C, 67.6; H, 10.2. $C_{15}H_{21}OP$ requires C, 67.9; H, 10.0%); the same compound was also produced from β -methylallylmagnesium bromide and phosphorus oxychloride. In the absence of air the phosphine and mercuric chloride in alcohol gave *tri- β -methylallylphosphine mercurichloride*, rhombic plates, m. p. 162° (Found: Cl, 15.2. $C_{15}H_{21}P.HgCl_2$ requires Cl, 15.2%). *Methyltri- β -methylallylphosphonium iodide*, from its components in ether, formed needles, m. p. 151°, from alcohol-ether (Found: I, 37.4. $C_{15}H_{24}PI$ requires I, 37.5%). *Tri- β -methylallylphosphine-p-benzoquinone*, precipitated by ether from mixed alcoholic solutions of its components, formed pale lemon-yellow stellate crystals, which darkened in the air or on heating, becoming black at 200° (Found: C, 70.8; H, 8.5. $C_{15}H_{25}O_2P$ requires C, 71.0; H, 8.3%).

Phenyldi- β -methylallylphosphine.—The compound (15 g.) was obtained from the Grignard reagent and phenyldichlorophosphine, and had b. p. 148°/13 mm., d_4^{25} 0.9484, n_D^{25} 1.5485 (Found: C, 76.8; H, 9.0; P, 14.2; M, 223. $C_{14}H_{19}P$ requires C, 77.0; H, 8.8; P, 14.2%; M, 218). It gave the *mercurichloride*, rectangular plates, m. p. 140.5° (Found: Cl, 14.7. $C_{14}H_{19}P.HgCl_2$ requires Cl, 14.5%). *Phenylmethyldi- β -methylallylphosphonium iodide* separated in needles, m. p. 188° (decomp.), from alcohol-ether (Found: I, 34.9. $C_{15}H_{22}PI$ requires I, 35.2%). On mixing hot alcoholic solutions of mercuric iodide and excess of the methiodide, *phenylmethyldi- β -methylallylphosphonium mercuri-iodide* crystallised out on cooling as lemon-coloured needles, m. p. 133° (Found: I, 47.0; Hg, 24.5. $C_{15}H_{22}PI.HgI_2$ requires I, 46.7; Hg, 24.6%). Similarly, cadmium iodide and the methiodide gave the *cadmi-iodide*, needles, m. p. 114° [Found: I, 46.7; Cd, 10.5. $(C_{15}H_{22}PI)_2.CdI_2$ requires I, 46.7; Cd, 10.3%]. Addition of excess of bromine to the phosphine in ether gave a precipitate, which, on solution in hot alcohol and treatment with water until turbidity appeared, yielded *phenyldi-(β -dibromo- β -methylpropyl)phosphine oxide*, needles, m. p. 105°, from aqueous alcohol (Found: Br, 57.6. $C_{14}H_{19}OBr_2P$ requires Br, 57.7%).

p-Tolyldi- β -methylallylphosphine.—Prepared from the β -methylallyl Grignard reagent and *p*-tolyl-dichlorophosphine, the phosphine (11 g.) had b. p. 168°/23 mm., d_4^{25} 0.9426, n_D^{25} 1.5465 (Found: C, 77.4; H, 9.3; P, 13.3; M, 228. $C_{15}H_{21}P$ requires C, 77.5; H, 9.1; P, 13.4%; M, 232). It gave the *mercurichloride*, cubes, m. p. 164° (Found: Cl, 14.2. $C_{15}H_{21}P.HgCl_2$ requires Cl, 14.1%). *p-Tolyldi- β -methylallylphosphonium iodide* crystallised in needles, m. p. 94°, from alcohol-ether (Found: I, 33.8. $C_{16}H_{24}PI$ requires I, 33.9%) and yielded *p-tolylmethyldi- β -methylallylphosphonium mercuri-iodide*, pale-yellow prisms, m. p. 79° (Found: I, 46.1; Hg, 24.1. $C_{16}H_{24}PI.HgI_2$ requires I, 45.9; Hg, 24.2%).

p-Xylyldi- β -methylallylphosphine.—The phosphine (12 g.) was obtained from β -methylallylmagnesium bromide and *p*-xylyldichlorophosphine; it had b. p. 166°/16 mm., d_4^{25} 0.9402, n_D^{25} 1.5450 (Found: C, 77.8; H, 9.4; P, 12.3. $C_{15}H_{23}P$ requires C, 78.0; H, 9.4; P, 12.6%). The *mercurichloride* separated in prisms, m. p. 201—202° (Found: Cl, 13.7. $C_{15}H_{23}P.HgCl_2$ requires Cl, 13.7%). *p-Xylylmethyldi- β -methylallylphosphonium iodide* crystallised in prisms, m. p. 161°, from alcohol-ether (Found: I, 32.5. $C_{17}H_{25}PI$ requires I, 32.7%). It gave with mercuric iodide in alcohol the *mercuri-iodide*, pale yellow rhombic plates, m. p. 71° (Found: I, 45.5; Hg, 23.6. $C_{17}H_{25}PI.HgI_2$ requires I, 45.2; Hg, 23.8%), and with cadmium iodide, the *cadmi-iodide*, needles, m. p. 159° [Found: I, 44.0; Cd, 10.2. $(C_{17}H_{25}PI)_2.CdI_2$ requires I, 44.4; Cd, 9.8%].

p-Ethylphenyldi- β -methylallylphosphine.—This compound (12 g.), prepared from the Grignard reagent and *p*-ethylphenyldichlorophosphine, had b. p. 178°/20 mm., d_4^{25} 0.9360, n_D^{25} 1.5435 (Found: C, 77.7; H, 9.6; P, 12.4; M, 240. $C_{16}H_{23}P$ requires C, 78.0; H, 9.4; P, 12.6%; M, 246). The *mercurichloride* separated in prisms, m. p. 156° (Found: Cl, 14.1. $C_{16}H_{23}P.HgCl_2$ requires Cl, 13.7%). *p-Ethylphenylmethyldimethyl- β -allylphosphonium iodide*, rectangular plates, m. p. 153°, from alcohol-ether (Found: I, 32.4. $C_{17}H_{26}PI$ requires I, 32.7%), gave the *mercuri-iodide*, pale yellow needles, m. p. 82.5° (Found: I, 45.3; P, 23.5. $C_{17}H_{26}PI.HgI_2$ requires I, 45.2; P, 23.8%).

p-Isopropylphenyldi- β -methylallylphosphine.—Interaction of the Grignard reagent and *p*-isopropylphenyldichlorophosphine gave the phosphine (14 g.), b. p. 182.5°/19 mm., d_4^{25} 0.9279, n_D^{25} 1.5350 (Found: C, 77.9; H, 9.8; P, 11.8; M, 263. $C_{17}H_{25}P$ requires C, 78.4; H, 9.7; P, 11.9%; M, 260). Its *mercurichloride* was obtained in needles, m. p. 153° (Found: Cl, 13.4. $C_{17}H_{25}P.HgCl_2$ requires Cl, 13.3%).

p-Methoxyphenyldi- β -methylallylphosphine.—*p*-Methoxyphenyldichlorophosphine and di- β -methylallylmagnesium bromide reacted to give the phosphine (12 g.), b. p. 192°/20 mm., d_4^{25} 0.9948, n_D^{25} 1.5513 (Found: C, 72.3; H, 8.7. $C_{15}H_{21}OP$ requires C, 72.6; H, 8.6%). Its *mercurichloride* separated in cubes, m. p. 181° (Found: Cl, 13.8. $C_{15}H_{21}OP.HgCl_2$ requires Cl, 13.6%). *p-Methoxyphenylmethyldi- β -methylallylphosphonium iodide*, needles, m. p. 134.5°, from water (Found: I, 32.3. $C_{16}H_{24}OPI$ requires I, 32.5%) gave the *mercuri-iodide*, pale yellow prisms, m. p. 71° (Found: I, 45.0; Hg, 23.7. $C_{16}H_{24}OPI.HgI_2$ requires I, 45.1; Hg, 23.7%), and the *cadmi-iodide*, needles, m. p. 132° [Found: I, 44.2; Cd, 10.1. $(C_{16}H_{24}OPI)_2.CdI_2$ requires I, 44.3; Cd, 9.8%].

p-Bromophenyldi- β -methylallylphosphine.—Obtained from di- β -methylallylmagnesium bromide and *p*-bromophenyldichlorophosphine, this phosphine (14 g.) had b. p. 189°/18 mm., d_4^{25} 1.2094, n_D^{25} 1.5752 (Found: C, 56.7; H, 6.3; P, 10.3; M, 293. $C_{14}H_{19}BrP$ requires C, 56.6; H, 6.1; P, 10.4%; M, 297). The *mercurichloride* was obtained in cubes, m. p. 194° (Found: Cl, 12.4. $C_{14}H_{19}BrP.HgCl_2$ requires Cl, 12.5%). *p-Bromophenylmethyldi- β -methylallylphosphonium iodide*, cubes, m. p. 174°, from alcohol-ether (Found: I, 28.8. $C_{15}H_{21}BrPI$ requires I, 28.9%), yielded the *mercuri-iodide*, pale yellow needles, m. p. 67° (Found: I, 42.8; Hg, 22.4. $C_{15}H_{21}BrPI.HgI_2$ requires I, 42.6; Hg, 22.4%) and the *cadmi-iodide*, needles, m. p. 178° [Found: I, 40.8; Cd, 9.3. $(C_{15}H_{21}BrPI)_2.CdI_2$ requires I, 40.8; Cd, 9.0%]. On adding bromine to the phosphine in ether until a brown colour persisted, there was deposited an oil which solidified on being kept in a vacuum; on dissolving the solid in alcohol, adding water until turbidity developed, and allowing the mixture to stand, there formed crystals of *p-bromophenyldi-(β -dibromo- β -methylpropyl)phosphine oxide*, needles, m. p. 152°, from alcohol (Found: C, 26.6; H, 2.9; Br, 63.2; non-nuclear Br, 51.3. $C_{14}H_{19}OBr_2P$ requires C, 26.6; H, 2.9; Br, 63.1; non-nuclear Br, 50.5%).

1450 Bergmann and Japhé: Bromination of Dimethoxystilbenes.

Preparation of the Arsines.—To the allyl or β -methylallyl Grignard reagent, prepared as already described, was added arsenic trichloride (6.8 c.c.) in ether (50 c.c.) or phenyldi-iodoarsine (51 g., obtained by the method of Steinkopf and Smie, *Ber.*, 1926, 59, 1461) in ether (200 c.c.). The isolation and purification of the arsine were also effected by redistillation under low pressure in carbon dioxide.

Phenyldiallylarsine.—This arsine (9 g.) was prepared by the interaction of allylmagnesium bromide and phenyldi-iodoarsine; it had b. p. $131^{\circ}/10$ mm. (Found: C, 61.3; H, 6.4; As, 31.3. $C_{11}H_{11}As$ requires C, 61.5; H, 6.5; As, 32.0%). It formed the *mercurichloride*, needles, m. p. 120° (Found: Cl, 13.8. $C_{11}H_{11}As.HgCl_2$ requires Cl, 14.0%).

Tri- β -methylallylarsine.—The compound (6 g.), obtained from β -methylallylmagnesium bromide and arsenic trichloride, had b. p. $114^{\circ}/15$ mm. (Found: C, 59.3; H, 8.7; As, 31.4. $C_{12}H_{14}As$ requires C, 60.0; H, 8.8; As, 31.2%). It yielded the *mercurichloride*, needles, m. p. $96-97^{\circ}$ (decomp.), from glacial acetic acid (Found: Cl, 14.2. $C_{12}H_{14}As.HgCl_2$ requires Cl, 13.9%), and *methyltri- β -methylallyl-arsonium iodide*, long rectangles, m. p. 129° (slight decomp.), from alcohol (Found: I, 33.0. $C_{12}H_{14}AsI$ requires I, 33.2%).

Phenyldi- β -methylallylarsine.—Interaction of the β -methylallyl Grignard reagent and phenyldi-iodoarsine gave the arsine (15 g.), b. p. $153^{\circ}/13$ mm., d_4^{25} 1.1200 (Found: C, 63.7; H, 7.5; As, 28.7. $C_{14}H_{19}As$ requires C, 64.1; H, 7.3; As, 28.6%). It formed *phenylmethyl-di- β -methylallylarsonium iodide*, needles, m. p. 163° (slight decomp.), from water (Found: I, 31.4. $C_{15}H_{21}AsI$ requires I, 31.4%).

Preparation of the Stannanes.—Triethylchlorotin, b. p. $209-210^{\circ}$, and diethyldichlorotin, m. p. 84° , were obtained by the methods of Kocheshkov (*J. Gen. Chem. Russia*, 1934, 4, 1359; 1935, 5, 211). **Tri-*n*-butylchlorotin** (40 g.) was prepared by heating (oil-bath) a mixture of tetra-*n*-butyltin (39 c.c.) and tin tetrachloride (4.6 c.c.) at 230° for 3 hours, and fractionating the product under low pressure; it had b. p. $172^{\circ}/25$ mm. (Found: Cl, 11.1. $C_{12}H_{27}SnCl_3$ requires Cl, 10.9%). **Di-*n*-butyldichlorotin** (20 g.) was obtained by heating a mixture of tetra-*n*-butyltin (16.5 c.c.) and tin tetrachloride (5.9 c.c.) for 3 hours at 240° , and recrystallising the product from light petroleum with cooling to -20° ; it formed plates, m. p. 40.5° (Found: Cl, 23.3. $C_8H_{19}SnCl_2$ requires Cl, 23.3%).

The chlorotin in benzene or ether was added to the allyl Grignard solution under hydrogen. After removal of the solvent and diallyl by distillation in carbon dioxide, the residue was dissolved in benzene (80 c.c.), the solution shaken with dilute sodium hydroxide solution to remove any traces of chloro-compound and then dried ($CaCl_2$), and the stannane isolated by distillation under low pressure in carbon dioxide.

Triethylallyltin.—This compound (21 g.) was prepared from the allyl Grignard solution and triethylchlorotin (30 g.) in benzene (90 c.c.), and had b. p. $76-77^{\circ}/10$ mm. (Found: C, 43.9; H, 8.3; Sn, 48.0. $C_6H_{13}Sn$ requires C, 43.8; H, 8.1; Sn, 48.1%).

Diethyldiallyltin.—Obtained by the action of the Grignard solution on diethyldichlorotin (16.8 g.) in benzene (60 c.c.), this compound (9 g.) had b. p. $99-100^{\circ}/17$ mm. (Found: C, 46.0; H, 7.7; Sn, 45.9. $C_{10}H_{20}Sn$ requires C, 46.3; H, 7.8; Sn, 45.9%).

Tri-*n*-butylallyltin.—The interaction of allylmagnesium bromide and tri-*n*-butylchlorotin (40 g.) in ether (120 c.c.) gave this compound as a liquid (30 g.), b. p. $155^{\circ}/17$ mm. (Found: C, 54.1; H, 9.8. $C_{18}H_{39}Sn$ requires C, 54.4; H, 9.8%).

Di-*n*-butyldiallyltin.—This compound (9.6 g.), prepared from the Grignard reagent and di-*n*-butyldichlorotin (19 g.) in ether (60 c.c.), had b. p. $145-146^{\circ}/17$ mm. (Found: C, 53.2; H, 9.1. $C_{14}H_{28}Sn$ requires C, 53.2; H, 9.0%).

The following derivatives were also prepared. **Ethyltrichlorotin** (6 g.) was obtained by refluxing tetraethyltin (7.9 c.c.) and tin tetrachloride (42 c.c.) for 24 hours and fractionating the product; it had b. p. $196-198^{\circ}$ (Found: Cl, 42.3. $C_6H_9SnCl_3$ requires Cl, 41.9%). After standing, a solution of 15 g. of allylstannonic acid (Found: Sn, 62.4. Calc. for $C_8H_9O_2Sn$: Sn, 61.5%) in a mixture of 50 c.c. of hydrobromic acid (d 1.5) and 50 c.c. of water deposited 40 g. of *allylpentabromostannic acid* (Found: Br, 71.2. $C_8H_7Br_5Sn$ requires Br, 71.2%); it separated in small, pale yellow cubes, soluble in water but not in organic solvents, and decomposed on heating.

The physical measurements here recorded were carried out with standardised apparatus, and all relevant corrections were applied. The yields given are not of crude, but of fully purified substance. Combustions were carried out by using lead chromate-copper oxide mixtures, determinations of phosphorus by the method of Davies and Davies (*J.*, 1931, 1207), of arsenic by that of Lewis and Davis (*J.*, 1939, 286), of tin by that of Gilman and King (*J. Amer. Chem. Soc.*, 1929, 51, 1213), and of mercury, cadmium, and iodine in complex salts by the method of Mannheim (*Annalen*, 1905, 341, 192).

274. Bromination of Dimethoxystilbenes.

By FELIX BERGMANN and HELENE JAPHÉ.

2 : 2'- and 3 : 3'-Dimethoxystilbene can be converted in a two-step process into symmetrical dibromodimethoxystilbenes. The 2 : 2'-compound is substituted in positions 5 and 5'.

In a recent publication (Bergmann and Schapiro, *J. Org. Chem.*, 1947, 12, 57) it was reported that 2-methoxystilbene undergoes nuclear bromination with such ease that in place of the expected dibromide there was obtained 5-bromo-2-methoxystilbene dibromide. We have now extended this observation to symmetrical dimethoxystilbenes.

Auwers (*Ber.*, 1903, 36, 1888), using excess of bromine, converted 4 : 4'-dimethoxystilbene into 3 : 5 : 3' : 5'-tetrabromo-4 : 4'-dimethoxystilbene dibromide. In this case, both positions

ortho to the methoxyl group are equivalent, whereas the *para* position is substituted by an olefinic chain. However, no disturbing effect is to be expected from this chain, as in all known cases the speed of addition of bromine to the central double bond of a stilbene is greater than that of nuclear substitution. The CHBr group is unlikely to exert any influence on this latter reaction, because Bance, Barber, and Woolman (*J.*, 1943, 1) observed the complete inertness of stilbene dibromide towards bromination in the ring. Therefore we assumed that in 2:2'-dimethoxystilbene dibromide the methoxy-groups would direct the attack of bromine exclusively. This was borne out by experiment.

After saturation of the double bond of 2:2'-dimethoxystilbene by bromine, substitution proceeded slowly, and although exactly 3 mols. of bromine were added, the reaction product was a mixture which could not be separated. It was, therefore, treated directly with potassium iodide. The mixture of bromostilbenes, so obtained, could be separated by fractional crystallisation into two substances of m. p. 214° and 130°, severally, which upon addition of 1 mol. of bromine yielded "dibromides" of m. p. 256° and 225° respectively. The compound of m. p. 214° is a dibromo-2:2'-dimethoxystilbene and was identified as the 5:5'-dibromoderivative by direct comparison with an authentic specimen (Ashley and Harris, *J.*, 1946, 567).

The substance of m. p. 130° contains only one bromine atom. That it was 5-bromo-2:2'-dimethoxystilbene was proved by its conversion *via* its dibromide into 5:5'-dibromo-2:2'-dimethoxystilbene dibromide. The reason for the incomplete conversion of 2:2'-dimethoxystilbene into the latter is to be found in the low reaction velocity. The monobromo-dibromide is sparingly soluble in chloroform, and if the bromine solution is added slowly, this compound has time to crystallise out, thus avoiding further bromination in the second ring. The preparation of the dibrominated bromide in nearly quantitative yield is, however, achieved easily, if excess bromine is added *at once* to a very dilute chloroform solution of 2:2'-dimethoxystilbene. This method thus presents a much easier route to 5:5'-dibromo-2:2'-dimethoxystilbene than the procedure of Ashley and Harris (*loc. cit.*).

3:3'-Dimethoxystilbene is converted smoothly into a dibromo-3:3'-dimethoxystilbene dibromide and hence into the corresponding stilbene; by analogy, these are deemed to be the 2:2'-dibromo-5:5'-dimethoxy-compounds, although we were unable to oxidise the stilbene to the expected 2-bromo-5-methoxybenzoic acid.

EXPERIMENTAL.

2:2'-Dimethoxystilbene.—By the procedure of Baumann and Fromm (*Ber.*, 1891, **24**, 1441), the required *o*-methoxythiobenzaldehyde is obtained mainly as a tough syrup and crystallizes only partly. However, the syrupy mass gave as good a yield (*ca.* 30%) upon thermal decomposition as did the crystalline portion. The crude stilbene was purified by distillation, b. p. 180–190°/0.5 mm., and then crystallized quickly upon trituration with methanol. It formed clusters of needles from butanol and prisms from toluene; m. p. 140°.

Bromination. (1) The stilbene (0.7 g.) was dissolved in chloroform (5 c.c.), and bromine (1.4 g.; 3 mols.) in the same solvent (5 c.c.) was added dropwise during 5 mins. The first third was decolorised instantaneously, then the speed of reaction slackened, and after addition of the second third of bromine a precipitate appeared. Decolorisation of the last third of bromine was very slow and was completed by warming on a water-bath. After the evolution of hydrogen bromide had ceased, the solvent was evaporated and the residue treated with methanol; yield 1.3 g., m. p. 218–220°. The product was not homogeneous, and crystallisation from xylene did not give a pure compound. It was, therefore, suspended in acetone (25 c.c.) and heated under reflux with sodium iodide (1 g.) for 3 hours. After evaporation of the solvent and addition of thiosulphate, a white substance was obtained. Upon recrystallisation from toluene, appeared first needles, then plates. They were separated by fractional crystallisation. The needles finally had m. p. 214° (Found: C, 48.4; H, 3.6. Calc. for $C_{16}H_{14}O_2Br_2$: C, 48.2; H, 3.5%) and were identified (mixed m. p.) as 5:5'-dibromo-2:2'-dimethoxystilbene described by Ashley and Harris (*loc. cit.*). The plates, recrystallised from isopropanol and then from light petroleum (b. p. 80°), formed glistening, elongated plates, m. p. 130° (Found: C, 60.0; H, 4.7. $C_{16}H_{14}O_2Br$ requires C, 60.2; H, 4.7%), of the *monobromostilbene*.

(2) 2:2'-Dimethoxystilbene (0.8 g.) was treated with bromine (2 mols.) in chloroform solution, and the product triturated with light petroleum. The 5-bromo-dibromide (1.6 g.; 100%) crystallised from toluene in colourless parallelepipeds with cut-off ends, m. p. 225° (Found: C, 39.8; H, 3.2. $C_{16}H_{14}O_2Br_3$ requires C, 40.1; H, 3.1%). It was identical with the compound formed by addition of bromine to the above monobromostilbene, into which it was converted by debromination with sodium iodide in acetone.

When the monobromostilbene was dissolved in chloroform and treated *at once* with excess of bromine, the dibromo-dibromide, m. p. 244° (see below), resulted.

(3) To 2:2'-dimethoxystilbene (6 g.; 1/40 mol.) in chloroform (50 c.c.) was added *at once* a solution of excess of bromine (20 g.; 5/40 mol.) in chloroform (50 c.c.), and the solution left overnight. The crude product (13.5 g.; 97%) had m. p. 244° and was difficult to recrystallise in greater amounts, because of decomposition. Small samples could be recrystallised from acetic anhydride, large volumes of xylene, or nitrobenzene. The products then showed different m. p.s; e.g., from xylene prisms of m. p. 245°, and from nitrobenzene of m. p. 256°. All these samples of 5:5'-dibromo-2:2'-dimethoxystilbene dibromide

showed identical analyses (Found : C, 34.2; H, 2.6. $C_{14}H_{14}O_2Br_4$ requires C, 34.4; H, 2.5%) and were quantitatively converted into the corresponding stilbene by debromination with sodium iodide or by the cuprous chloride-pyridine procedure of Bance *et al.* (*loc. cit.*).

3 : 3'-Dimethoxystilbene.—The desulphuration of *m*-methoxythiobenzaldehyde started at 200° and was completed by heating to 230° for 35 mins. The crude reaction product was mixed with an equal weight of copper-bronze and distilled in a vacuum; b. p. 180–182°/0.1 mm. The distillate crystallised spontaneously. From isopropanol it formed prismatic plates, m. p. 101°; yield 10%.

Bromination. To the stilbene (1.3 g.) in chloroform (10 c.c.) was added dropwise a solution of bromine (2.6 g.) in chloroform (8.3 c.c.). When addition was complete, 2 : 2'-dibromo-5 : 5'-dimethoxystilbene dibromide crystallised out. The solvent was evaporated, and the residue treated with ethanol; yield 2.7 g. (90%). From acetic anhydride the substance crystallises in hexagonal plates, m. p. 236° (Found : C, 34.6; H, 2.5. $C_{14}H_{14}O_2Br_4$ requires C, 34.4; H, 2.5%). Debromination with potassium iodide in acetone, as above, gave a 90% yield of 2 : 2'-dibromo-5 : 5'-dimethoxystilbene, which crystallised from toluene as prismatic rods, m. p. 154–155° (Found : C, 48.3; H, 3.7. $C_{14}H_{14}O_2Br_2$ requires C, 48.2; H, 3.5%).

The authors wish to thank Dr. J. N. Ashley, who carried out the comparison of 5 : 5'-dibromo-2 : 2'-dimethoxystilbene with an authentic specimen, prepared by him.

275. Benzylamine Analogues of Chemotherapeutic Diamidines.

By ADRIEN ALBERT, JOHN A. MILLS, and RICHARD ROYER.

To help trace the origins of the outstanding chemotherapeutic properties of aromatic diamidines of type (I), the simpler bases of type (II) were synthesised for the first time.

THE researches of Ewins and his colleagues (*cf.* Ashley, Barber, Ewins, Newbery, and Self, *J.*, 1942, 103) established that aromatic diamidines of type (I), especially *c*, *d*, *e*, and *f*, have outstanding antiparasitic properties against protozoa. It is not known (i) whether the anti-protozoal activity of these substances is derived largely from their having two well-ionized and mutually independent basic groups held at a distance from one another, or (ii) whether such activity depends specifically on the amidine group which may conceivably function by assisting adsorption, through the resonance of its ion, or by interfering with a similarly constituted metabolite in the parasite.

(a) X absent; (b) X = CH₂; (c) X = O;
(d) X = O·[CH₂]₃·O; (e) X = O·[CH₂]₆·O; (f) X = CH=CH.

At this stage we propose only to examine hypothesis (i). This cannot be tested simply by replacing each amidine group by an amino-group because the basic strength of the latter would be enormously lowered through interaction with the benzene ring (*cf.* aniline and methylamine, Table I), leading to an almost complete absence of kations in neutral solution. If, however, the amino-group is insulated from the aromatic ring by a methylene group, the base-weakening resonance is repressed and a high degree of ionization results (*cf.* benzylamine and methylamine, Table I). That the ionization of amidines is little affected by the presence of an aromatic substituent is now shown for the first time (Table I).

TABLE I.

Ionisation of certain bases under physiological conditions.

Compound.	pK _a , 20° (water).	Source of value,	% ionized pH 7.

Aniline	4.65	D	0.5
Benzylamine	9.4	E	99.5

- A. Schwarzenbach and Lutz, *Helv. Chim. Acta*, 1940, **23**, 1162.
B. Determined potentiometrically by Mr. R. Goldacre (for details of method, see Albert and Goldacre, *J.*, 1946, 706).
C. Britton and Williams, *J.*, 1935, 796.
D. Hall and Sprinkle, *J. Amer. Chem. Soc.*, 1932, **54**, 3469.
E. Carothers, Bickford, and Hurwitz, *ibid.*, 1927, **49**, 2908.

The preparation of the bisbenzylamine compounds (II, *a*—*f*) was accordingly undertaken to permit of biological comparison with the corresponding diamidines (I), in particular with *c* (Phenamidine), *d* (Propamidine), *e* (Pentamidine), and *f* (Stilbamidine).

The corresponding dinitriles were hydrogenated by the method of Schwoegler and Adkins (*J. Amer. Chem. Soc.*, 1939, **61**, 3499) for aliphatic amines, methanolic ammonia being used in the presence of Raney-nickel catalyst at 110° for 20 minutes under 1200 lb./sq. in. pressure. In this way were prepared *pp'*-bisaminomethyldiphenyl (II, *a*), *pp'*-bisaminomethyldiphenylmethane (II, *b*), characterized as its dibenzoyl derivative, *pp'*-bisaminomethyldiphenyl ether (II, *c*), 1 : 3-(*pp'*-bisaminomethyldiphenoxy)propane (II, *d*), 1 : 5-(*pp'*-bisaminomethyldiphenoxy)pentane (II, *e*), and *pp'*-bisaminomethylstilbene (II, *f*).

Before attempting the reduction of 4 : 4'-dicyanostilbene, it was confirmed that these conditions were not severe enough to reduce the double bond in *trans*-4 : 4'-diaminostilbene. The latter was made by reducing the mixture of dinitro- and dinitroso-stilbenes formed by the violent reaction of *p*-nitrotoluene and methanolic sodium hydroxide (Fischer and Hepp, *Ber.*, 1893, **26**, 2232). The mechanism of this reaction was investigated by Green, Davies, and Horsfall (*J.*, 1907, **91**, 2076), but no yields were given. As insufficient details exist in the literature for the safe and successful conduct of this reaction for preparative purposes, a detailed account is given in the experimental section.

The products (II, *a*—*f*) are white, water-insoluble solids which absorb carbon dioxide rapidly from the air but are stable in the form of their white, readily crystallising salts, of which the diacetates are more soluble than the dihydrochlorides and are to be preferred for biological work. That these substances possess the predicted basic strength may be inferred from the example quoted in Table II. This table also shows that, both here and in the diamidines, the two basic groups are too far apart for the ionization of the first to exert an adverse Coulombic effect on that of the second, such as is seen in trimethylenediamine (pK_a 9.8 and 7.0).

TABLE II.

Ionisation of certain diacid bases.

Compound.	pK_a values, 20° (50% ethanol).	Source of value.	Approx. % ionised in water at pH 7.
" Propamidine " (I, <i>d</i>)	11.6 & 10.8 (M/300)	B (see Table I)	100 & 100
<i>pp'</i> -Bisaminomethyldiphenyl- methane (II, <i>b</i>)	9.28 & 8.10 (M/160)		100 & 97

Von Braun (*Ber.*, 1937, **70**, 979) claimed to have produced (II, *a*) by the action of liquid ammonia on *pp'*-bisbromomethyldiphenyl; it is possible that his material was contaminated by secondary amines.

Note added in Proof.—Compounds (I, *c*—*f*) and (II, *a*—*f*) were kindly compared by Mr. L. G. Goodwin in experimental animal tests against *Trypanosoma rhodesiense*, *T. congolense*, *Plasmodium gallinaceum*, *Leishmania donovani*, and *Entamoeba histolytica*. No activity was shown by any Type (II) compound. We are also grateful to Prof. S. D. Rubbo for testing the same series, *in vitro*, against *Cl. welchii*, *Strept. pyog.*, *Staph. aur.*, *B. coli*, and *B. Proteus*. Only (I, *d* and *e*) showed outstanding activity.

Thus, unless it can be shown that these organisms possess an enzyme specifically destroying Type (II) compounds, hypothesis (i) is no longer tenable.

EXPERIMENTAL.

[The microanalysis of bisaminomethyldiphenyl and its hydrochloride were carried out by one of us (J. A. M.); the remainder were done by Miss J. Fildes, who is hereby thanked.]

General.—The dinitrile (15 g.), Raney-nickel catalyst (*ca.* 5 ml. of sludge), and methanolic ammonia saturated at 0° (150 ml.) were placed in a chilled-steel hydrogenation bomb (unlined) with two $\frac{1}{8}$ in. steel balls. These proportions allow about 7 mols. of ammonia, per cyano-group. Hydrogen was admitted at an initial pressure of 1300 lb./sq. in., and maintained at about 1200 lb. whilst the bomb was heated to 110° in 30 minutes with shaking. Uptake of hydrogen began at about 70°. It was rapid and approximately that required by theory. The autoclave was allowed to cool, and then chilled in ice. It was opened, and the contents filtered quickly with the assistance of some methanolic ammonia, in which the amines dissolve much better than in methanol. Carbon dioxide was excluded as much as possible from this and subsequent operations. The solvent was recovered by using a bath at 140° and applying a vacuum towards the end. The amines (crude yields about 90%) solidified on cooling and sometimes contained colloidal nickel hydroxide which caused foaming when the solids were distilled.

pp'-Bisaminomethyldiphenyl (II, *a*).—This was purified by distillation (*b. p.* 180°/0.5 mm.) and recrystallisation from 10 parts of toluene. The yield of pure material was 80%. A slightly under-

hydrogenated batch supersaturated badly. The substance is soluble in hot alcohol, benzene, and ethyl acetate, and in cold pyridine (Found: C, 79.5; H, 7.5; N, 13.3. Calc. for $C_{14}H_{15}N_3$: C, 79.2; H, 7.6; N, 13.2%). The compound and its derivatives had the following m. ps. (values of v. Braun, *loc. cit.*, in parenthesis): base, 144–145° (135°); picrate, 232–235° (decomp.) (222°); dibenzoyl derivative, 249–250° (243°); diacetyl derivative, 281–283° (272°). The dihydrochloride was formed by crystallisation from hot dilute hydrochloric acid. It is soluble in about 100 parts of cold water and readily precipitated by extra chloride ions (Found: C, 59.15; H, 6.3; Cl, 24.7. $C_{14}H_{15}N_3Cl_2$ requires C, 58.95; H, 6.4; Cl, 24.9%). The crystals developed a blue tint on exposure to sunlight.

pp'-Bisaminomethylidiphenylmethane (II, b).—This was purified by distillation at 0.5 mm., followed by dissolution in 5 parts of boiling benzene and treatment with 5 parts of light petroleum (b. p. 60–90°). The white crystals, m. p. 90° (80% yield), were dried in a vacuum over shredded paraffin. The compound is very soluble in alcohol without gradient, sparingly soluble in ether (Found: C, 79.4; H, 7.9; N, 12.2. $C_{15}H_{16}N_2$ requires C, 79.6; H, 8.0; N, 12.4%). The dihydrochloride (m. p. over 350°) is exceptional in this series in that it is difficult to precipitate with chloride ions; it is almost insoluble in alcohol and unaffected by light. The dibenzoyl derivative was prepared with benzoyl chloride in 10 volumes of pyridine (yield 90%) as white crystals from chlorobenzene, m. p. 224° (230° corr.), sparingly soluble in benzene, acetone, and alcohol (Found: N, 6.4. $C_{22}H_{20}O_2N_2$ requires N, 6.45%).

pp'-Bisaminomethylidiphenyl ether (II, c).—This was distilled (b. p. 186°/0.3 mm.), giving crystals (70% recovery) which began to melt at 56° and were completely molten at 77° (? double m. p.). The product was readily soluble in ethyl and amyl alcohols and in boiling toluene or acetone with gradient; only slightly soluble in ether and in light petroleum (Found: C, 73.0; H, 7.1; N, 12.2. $C_{14}H_{14}ON_2$ requires C, 73.6; H, 7.1; N, 12.3%). The dihydrochloride does not melt below 360°. The diacetate (m. p. 156°, anhydrous) was formed by dissolving the base in 8*N*-acetic acid at 50°, precipitating with acetone, and drying at 110°. It was readily soluble in cold water and hot ethanol.

1:3-(*pp'*-Bisaminomethylidiphenyloxy)propane (II, d).—This was purified by distillation (b. p. 242°/0.5 mm.) and then recrystallised from alcohol, m. p. 90–91° (70% yield). It is sparingly soluble in boiling benzene; moderately so in boiling acetone. The dihydrochloride is sparingly soluble in cold water and readily soluble in hot water; it sinters at ca. 290° but does not melt below 360°. The diacetate, m. p. 178°, prepared as above, is readily soluble in cold water, moderately in boiling alcohol, and insoluble in acetone (Found: C, 62.0; H, 7.4; N, 6.85. $C_{17}H_{22}O_2N_2$, $2C_2H_5O_2$ requires C, 62.0; H, 7.4; N, 6.9%).

1:5-(*pp'*-Bisaminomethylidiphenyloxy)pentane (II, e).—This was purified through the acetate without previous distillation. The base (70% yield), m. p. 74–75°, from aqueous ethanol, is readily soluble in pyridine and in methanol and has good gradients in toluene and chlorobenzene. It is very slightly soluble in ether and in light petroleum. The dihydrochloride is soluble in cold water and insoluble in ethanol and acetone. It sinters at ca. 270° but does not melt below 360°. The diacetate, m. p. 161°, is very soluble in water, moderately in cold and readily in boiling ethanol, and insoluble in acetone (Found: C, 63.4; H, 7.8; N, 6.4. $C_{19}H_{26}O_2N_2$, $2C_2H_5O_2$ requires C, 63.55; H, 7.9; N, 6.45%).

pp'-Bisaminomethylstilbene (II, f).—This compound was purified by recrystallisation first from chlorobenzene and then from ethanol, giving crystals, m. p. 210–211° (decomp.) on rapid heating (yield 75%). They are soluble in about 27 parts of boiling ethanol, moderately soluble in boiling benzene or pyridine (with gradient), and almost insoluble in acetone, ether, or light petroleum (Found: C, 80.6; H, 7.6; N, 11.7. $C_{14}H_{15}N_2$ requires C, 80.6; H, 7.6; N, 11.8%). The dihydrochloride is moderately soluble in boiling water (with gradient) and insoluble in alcohol or acetone. The diacetate, m. p. 206–207°, solidifies at 210° and melts again at 255° (approx.) and is readily soluble in water, slightly soluble in boiling alcohol, and insoluble in acetone.

trans-pp'-Diaminostilbene.—A three-neck flask (capacity 1 l.) was fitted with an efficient mechanical stirrer, a 24-in. water-cooled bulb condenser, and a cork containing a thermometer, the bulb of which was pushed down below the 250 ml. level. The operation was conducted under a good hood.

Sodium hydroxide sticks (125 g.) were broken into coarse grit and refluxed in the flask with methanol (500 ml.) until dissolved (about 90 minutes), heat being supplied by a glycerol-bath at 100°. The flame was extinguished, and the thermometer momentarily withdrawn while molten *p*-nitrotoluene (50 g.) was rapidly added. After 30 seconds a violent reaction set in, the temperature rising to 105° and falling back to 90° when the condensed methanol returned to the flask. The flask contents became deep red. The glycerol-bath was then heated for ½ hour to keep the flask contents at 100°. The thermometer was then withdrawn, and a condenser, arranged for distillation, inserted. Concentrated hydrochloric acid (1 equiv.; 300 ml. of 39% w/v) was added down the upright condenser during 15 minutes with rapid stirring. The bath was then maintained at 120° until 400 ml. of methanol, altogether, had been collected. The product consisted of a mixture of dinitrodibenzyl, dinitrostilbene, and (mainly) dinitrostilbene. These substances were separated by Fischer and Hepp, but it was found more economical to reduce them together, *in situ*, taking advantage of the relative insolubility of diaminostilbene salts.

The temperature of the bath was lowered to 100°, and a solution of stannous chloride crystals (330 g.; 4 mols. per mol. of nitrotoluene) in concentrated hydrochloric acid (330 ml.), warmed to 80°, was added down the upright condenser during 15 minutes. Stirring and heating at 100° (bath temp.) were continued for 2 hours. The flask was then cooled and kept in ice for 2 days.

The precipitate of sodium chloride and diaminostilbene stannichloride was filtered off, pressed well, and extracted successively with 500, 200, and 50 ml. of boiling water, leaving about 1 lb. of sludge. The combined filtrates were boiled and treated with sodium hydroxide (ca. 350 ml. of 5*N*) until Orange-II paper was reddened. The mixture was heated for ½ hour on the boiling water-bath and again adjusted to reddish Orange-II. The precipitate was filtered hot, pressed, and washed until the filtrate ceased to redden phenolphthalein. The cake was dissolved in the minimum (ca. 300 ml.) of boiling *N*-hydrochloric acid, 75 ml. of 10*N*-hydrochloric acid were then added, and the whole refrigerated overnight. Next day the diaminostilbene hydrochloride was filtered off, dissolved in boiling water (150 ml.) containing 10*N*-hydrochloric acid (1 ml.), and treated with sodium hydroxide, as above. The cake was collected, pressed hard, washed well, and dried at 120°. The yield was 17.0 g. (45%) of orange powder, m. p. 214°.

This was purified by boiling with 20 parts of chlorobenzene, filtering hot, and cooling in ice for a day (85% recovery; m. p. 225–226°).

Finally, recrystallisation from dilute alcohol removed a trace of orange impurity and gave minute, almost colourless crystals, m. p. 227–228° equal to the highest uncorrected m. p.s in the literature (Calvin and Buckles, *J. Amer. Chem. Soc.*, 1940, **62**, 3324; Klinge, *Ber.*, 1883, **16**, 943).

The authors wish to thank Professors J. C. Earl and A. K. Macbeth for their interest in this work, and Dr. A. J. Ewins for supplying the dinitriles. This work was supported by the National Health and Medical Research Council, the Commonwealth Research Fund, and the Wellcome Foundation.

276. *The Crystal Structure of Ammonium Nitrate III, and Atomic Scattering Factors in Ionic Crystals.*

By T. H. GOODWIN and J. WHETSTONE.

The crystal structure of ammonium nitrate III has been redetermined in the light of revised optical and X-ray evidence.

IN the course of an investigation into the conditions of stability of ammonium nitrate III, the form normally stable from 32·3° to 84·2°, we measured the series of single-crystal rotation and oscillation photographs which we obtained, and compared our data with those of Hendricks, Posnjak, and Kracek (*J. Amer. Chem. Soc.*, 1932, **54**, 2776). Although there is general agreement between their observations and ours, there are certain marked discrepancies [see information in Tables II and III concerning the planes (002) and (004), (101), and (200)]. Moreover, there are frequently wide discrepancies between their observed and calculated intensities, as, for example, for the planes observed to have "moderate" intensities.

We are unable to account for the observational discrepancies, but for the rest, it seems possible that the authors were aware of the optical data which Hendricks, Deming, and Jefferson published later (*Z. Krist.*, 1933, **85**, 145) and, believing them to be correct, proposed a structure in conformation with them. They say that their agreement between observed and calculated intensities is only moderate. A difficulty in trying to explain these discrepancies is that although the authors state that the interfacial angles between the needle zone faces is 90° 0' (faces therefore $a\{100\}$ and $b\{010\}$) they quote no data derived directly from rotation, oscillation, or Weissenberg photographs about the a - or b -axes apart from the intensities of $\{001\}$ which we consider erroneous and for which they fail to record calculated intensities. We therefore decided to redetermine the structure.

Since ammonium nitrate III is stable only above 32°, all manipulations of the crystals had to be carried out above this temperature. The specimens used were grown from aqueous-alcoholic solution in a thermostatic hot-air chamber at 50°, and selected and mounted while still in the chamber. They were then rapidly transferred to the goniometer arcs while a stream of hot air at *ca.* 42° was allowed to flow over crystal and arcs alike. Optical goniometry revealed that the crystals, which were long needles, usually had only the four prism faces of the $\{110\}$ form present, the angle $(110):(1\bar{1}0)$ being 94°. There is probably no significance in this difference of habit between our crystals and those of Hendricks *et al.*

After the camera had been placed in position, hot air was introduced into it by a wide tube inserted through the lid and reaching down to near the level of the crystal, a thermometer being present in the air stream to ensure maintenance of a sufficiently high temperature (*ca.* 42°). The X-radiation employed was from the copper target of a Shearer tube with a nickel-foil filter. The following axes were measured: $a = 7\cdot14$, $b = 7\cdot65$, $c = 5\cdot83$ Å. These compare satisfactorily with the results of Hendricks *et al.*, *viz.*, $a = 7\cdot06$, $b = 7\cdot66$, $c = 5\cdot80$ Å. Examination of oscillation photographs about the a , b , and c axes revealed $\{0kl\}$ present only when k is even, $\{h0l\}$ present only when $h + l$ is even, $\{h\bar{h}0\}$ and $\{h\bar{h}l\}$ present in all orders. These extinctions are consistent with the space-group $Pbnm$ (V_h^{16}) assumed by the American investigators although Pbn (C_{2h}^3) is also possible. For preliminary calculations the space-group of higher symmetry $Pbnm$ was assumed.

The structure factors for planes of the $\{h\bar{h}0\}$ zone are the same for both space-groups and, as is shown later, the atomic positions were deduced by constructing a Fourier projection on (001). Since it was impossible to carry out work with heated crystals on the Weissenberg

instrument available, visual estimates of intensities had to be made from rotation and oscillation photographs, with consequent limitations of accuracy. It was found possible, using the atomic positions definitely located by the Fourier synthesis, to postulate a structure based on the symmetry elements of *Pbnm*, giving satisfactory agreement between observed and calculated intensities within the limits of accuracy of the work. In addition, the packing of the atoms in the unit cell is such that there is little possibility of changes in the relative positions indicated if on the one hand the projection on (001) is to be maintained while on the other the space-group is to be altered to *Pbn*; any such changes would increase the range of $\text{NH}_4 \dots \text{O}$ distances observed on the structure. Thus we consider that the choice of the space-group of higher symmetry, *Pbnm*, is justified.

In this space-group, then, eight asymmetric units are required, four being mirror images of the others, but as only four NH_4NO_3 units, *i.e.*, four NH_4^+ and four NO_3^- ions, are present, these must possess two-fold symmetry; since the space-group does not involve axes of rotation, the ions are restricted to central or planar symmetry. Both these types need to be considered for, though neither the tetrahedral NH_4^+ nor the planar NO_3^- group can have a centre of inversion when "at rest", in ammonium nitrate I, the form stable from 125° to the melting point at 169.5° , there is only one ion of each species in a cubic cell and therefore each must be rotating in a way which enables it to simulate cubic symmetry. In ammonium nitrate III rotation of the NH_4^+ and NO_3^- could confer on them pseudo-central symmetry. On the other hand, (a) the latter modification is stable at considerably lower temperatures and its ions are therefore less likely to be rotating in the solid state, and (b) the number of ions present is the minimum required if they are planar and at rest. We decided, therefore, to begin by placing the nitrate ions on the symmetry planes, but in view of the fact that the ammonium ions are more nearly spherical and therefore more readily capable of free rotation, we decided to consider their location at centres of inversion and on planes of symmetry in turn. In the latter case the co-ordinates of the ammoniacal nitrogen are :

$$(a) \ u_A, v_A, \frac{1}{4}; \ u_A, \bar{v}_A, \frac{3}{4}; \ \frac{1}{2} - u_A, \frac{1}{2} + v_A, \frac{1}{4}; \ \frac{1}{2} + u_A, \frac{1}{2} - v_A, \frac{3}{4}.$$

In the former they may be either :

$$(b) \ 0, 0, 0; \ 0, 0, \frac{1}{2}; \ \frac{1}{2}, \frac{1}{2}, 0; \ \frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \text{ or } (c) \ \frac{1}{2}, 0, 0; \ \frac{1}{2}, 0, \frac{1}{2}; \ 0, \frac{1}{2}, 0; \ 0, \frac{1}{2}, \frac{1}{2}.$$

For the nitrate ions two dispositions on the symmetry planes of the crystal are possible, *viz.*, so that all four atoms of each ion are on the (same) symmetry plane or so that the nitrogen and one oxygen are on the plane, the other oxygens being above and below this. In the first case pronounced negative optical birefringence would occur, the minimum refractive index α being perpendicular to the symmetry planes, *i.e.*, parallel to the *c*-axis (cf. potassium nitrate and aragonite; Bragg, "Atomic Structure of Minerals", Oxford Univ. Press, 1937, pp. 119 *et seq.*). In the second, γ , the greatest refractive index, would be parallel to *c*. In fact, γ is parallel to *c*, so that the second possibility is the correct one; since the optic axial angle is high ($2V \approx 90^\circ$) it follows that the plane of the ion must be quite oblique to both the *a* and the *b* axis.

The atomic co-ordinates of N and one O of the NO_3^- must therefore be as in (a) above but with parameters u_N, v_N and u_O, v_O . The other oxygens are in general (*i.e.*, eight-fold) positions :

$$(d) \ x, y, z; \ \bar{x}, \bar{y}, \frac{1}{2} + z; \ \frac{1}{2} - x, \frac{1}{2} + y, \frac{1}{2} - z; \ \frac{1}{2} + x, \frac{1}{2} - y, \bar{z}; \\ x, y, \frac{1}{2} - z; \ \bar{x}, \bar{y}, \bar{z}; \ \frac{1}{2} - x, \frac{1}{2} + y, z; \ \frac{1}{2} + x, \frac{1}{2} - y, \frac{1}{2} + z.$$

To locate the various atoms, we first considered the orders of (001) since they involve only the *z*-co-ordinates. For those the structure factor F_{00l} is :

$$F_{00l} = 8f(\text{O}) \cos 2\pi lz + 4f(\text{O}) \cos 2\pi \frac{l}{4} + 4f(\text{N}) \cos 2\pi \frac{l}{4} + 4f(\text{A}) \cos 2\pi \frac{l}{4},$$

$$\text{or} \quad F_{00l} = 8f(\text{O}) \cos 2\pi lz + 4f(\text{O}) \cos 2\pi \frac{l}{4} + 4f(\text{N}) \cos 2\pi \frac{l}{4} + 4f(\text{A}) \cos 2\pi \frac{l}{2}$$

according as the ammonium ion is situated on the symmetry plane or at a symmetry centre; $f(\text{O})$, $f(\text{N})$ and $f(\text{A})$ are the atomic scattering factors of oxygen, nitrate nitrogen, and ammonium respectively. Hendricks, Posnjak, and Kracek "assumed that $f(\text{A})$ for Cu-K radiation is

approximately the same as determined for Mo-*K* radiation diffracted from NH_4Cl (Wyckoff and Armstrong, *Z. Krist.*, 1929, **72**, 319), that $f(\text{O})$ is the same as for oxygen in nickel oxide (Cu-*K* radiation) (Wyckoff, *Physical Rev.*, 1930, **35**, 583; "Structure of Crystals", 2nd Edn., 1931, p. 100), and that $f(\text{N}) = 0.35 f(\text{O})$ independent of $\sin \theta/\lambda$. It is thus implied that, so far as the diffraction of *X*-rays is concerned, the nitrate ion approximates to a N^{5+} ion surrounded by three O^{2-} ions. In view of the completed *L* shells of nitrogen and oxygen in nitrate ions as formulated by chemists, we have preferred to regard the *f* values of these atoms as the same, with $f_0(\text{N}) = f_0(\text{O}) = 8$, f_0 being the value of *f* when $\theta = 0$. Of the various theoretical arguments in support of this view, we quote only two. It is well known that the polarising power of a cation increases with increasing charge and decreasing radius. Since the "radii" of N^{5+} and, say, Li^+ are quoted by, e.g., Pauling ("Nature of the Chemical Bond", 2nd Edn., p. 346) as 0.11 and 0.60 Å., respectively, it follows that the polarising power of the N^{5+} will be so great as to lead to N-O bonds which are essentially covalent. Secondly, the uniformity of structure of the nitrate ion as a planar equilateral triangle in which the central nitrogen has no tendency to be surrounded by more than three oxygens or other "anions", shows that the N-O bonds are directed in space and therefore are covalent, not electrovalent.

Using, then, these atomic scattering factors, we found that if the NH_4^+ ion is on the mirror plane *z* must have a value of between 0.06 and 0.07 in order to account for the observed relative intensities of (002), (004) and (006); *z* was selected as 0.06, equivalent to a distance of about 2.21 Å. for O . . . O in the nitrate ion, or 1.27 Å. for N . . . O, which latter value lies between the measurement of 1.21 Å. made by Elliott (*J. Amer. Chem. Soc.*, 1937, **59**, 1380) for the nitrate ion in sodium nitrate, and the value of 1.31 Å. calculated by Pauling on the basis of one double bond resonating between the three positions. If the ammonium ion was placed at a symmetry centre no such satisfactory relative intensities could be calculated.

We next drew, on scaled diagrams of the (001) plane, the traces of various particularly strong and particularly weak $\{hk0\}$ planes (excluding space-group halvings). On examining the resulting diagram with the assistance of a scale model of the nitrate ion (edge = O . . . O proportional to 2.21 Å.), arranged so that one O . . . O direction was perpendicular to the diagram, tentative positions for the atoms of this ion were obtained which permitted a reasonable location of the NH_4^+ ion on the symmetry plane. From these we calculated, after some slight adjustments, structure factors which were in approximate agreement with our qualitative estimates of intensity. In an endeavour to refine the structure we then made by visual estimation numerical assays of the intensities of as many as possible of the $\{hk0\}$ planes from rotation and oscillation photographs and constructed a Fourier projection on (001).

This projection proved far from satisfactory because, while indicating unequivocally the two oxygens in the general positions (*d*), it left considerable doubt as to the placing of the ammonium ion and the third oxygen on the reflection planes. One of these was revealed as a definite peak in the landscape but the other only as an upland region. According to whether and where the ammonium or oxygen is placed in this upland region three alternative structures are obtained which give *F* values for the $\{hk0\}$ planes of roughly the same magnitude as those estimated visually. However, by trial and error methods the ammonium ion was eventually placed in this region in a position which led to satisfactory agreement with the intensities of reflections over all three principal zones as well as for the $\{hkl\}$ planes. The nitrate nitrogen was suitably located on the line joining the "special" and "general" oxygens in the projection. In view of the large changes in structure amplitude brought about in certain planes by movements of the atoms of less than one-hundredth of the cell edge, and the impossibility of testing all the combinations of atomic positions within the tolerances allowed by the Fourier synthesis, the agreement between observed and calculated intensities is as good as can be expected.

TABLE I.

Atomic co-ordinates.

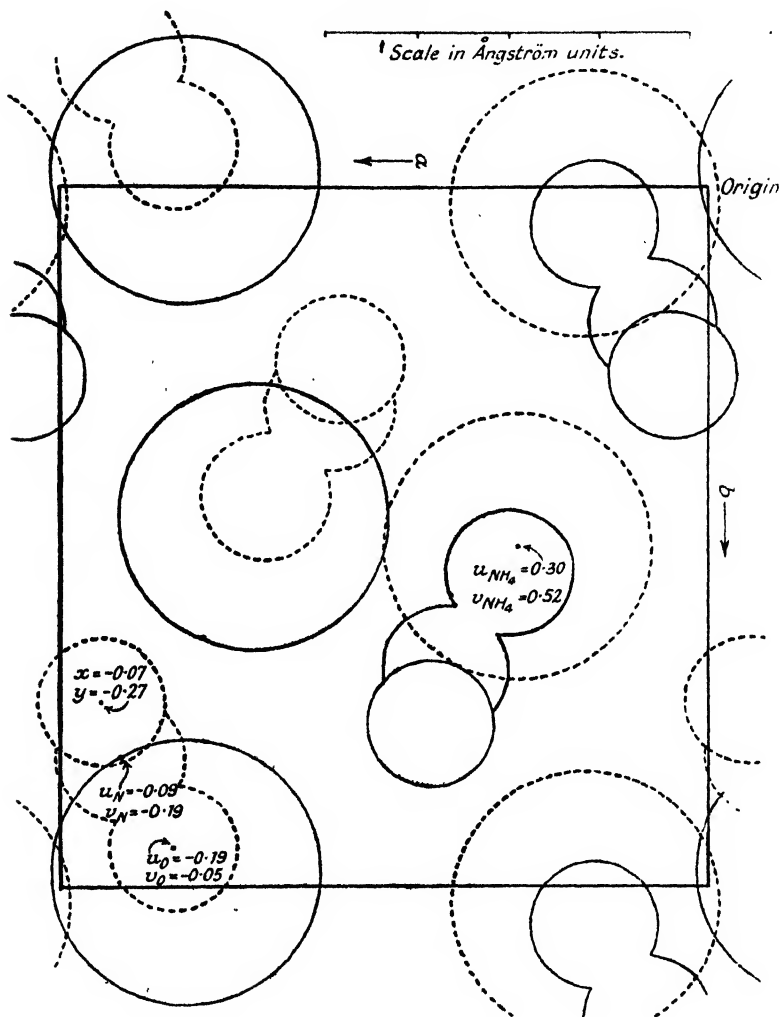

<i>x</i> = 0.05–0.06	<i>y</i> = 0.17–0.175–0.18	<i>z</i> = 0.06–0.07
<i>x_N</i> = 0.13–0.14	<i>v_N</i> = 0.14–0.145–0.15	<i>w_N</i> = 0.25
<i>x_O</i> = 0.30–0.29	<i>v_O</i> = 0.08–0.085–0.09	<i>w_O</i> = 0.25
<i>x_{NH₄}</i> = 0.30–0.32	<i>v_{NH₄}</i> = –0.02 to –0.03	<i>w_{NH₄}</i> = –0.25

Table I gives the limits within which we consider the parameters of the various atoms to lie, the figures in *italics* being those used in calculating the structure factors and intensities of Tables II, III, and IV.

Since the crystals were thin needles of nearly square cross-section, it was considered unnecessary to apply absorption corrections to the observed intensities of the $\{h k 0\}$ planes. They have, however, been applied to those of the other prism zones, though not to the $\{h k l\}$ planes, calculations of which were made rather as a final check.

In Table II are given first the observed intensities of the planes of the $\{h k 0\}$ zone. Then in col. 3 are recorded the structure factors calculated from the final ionic model, the four atoms

FIG. 1.

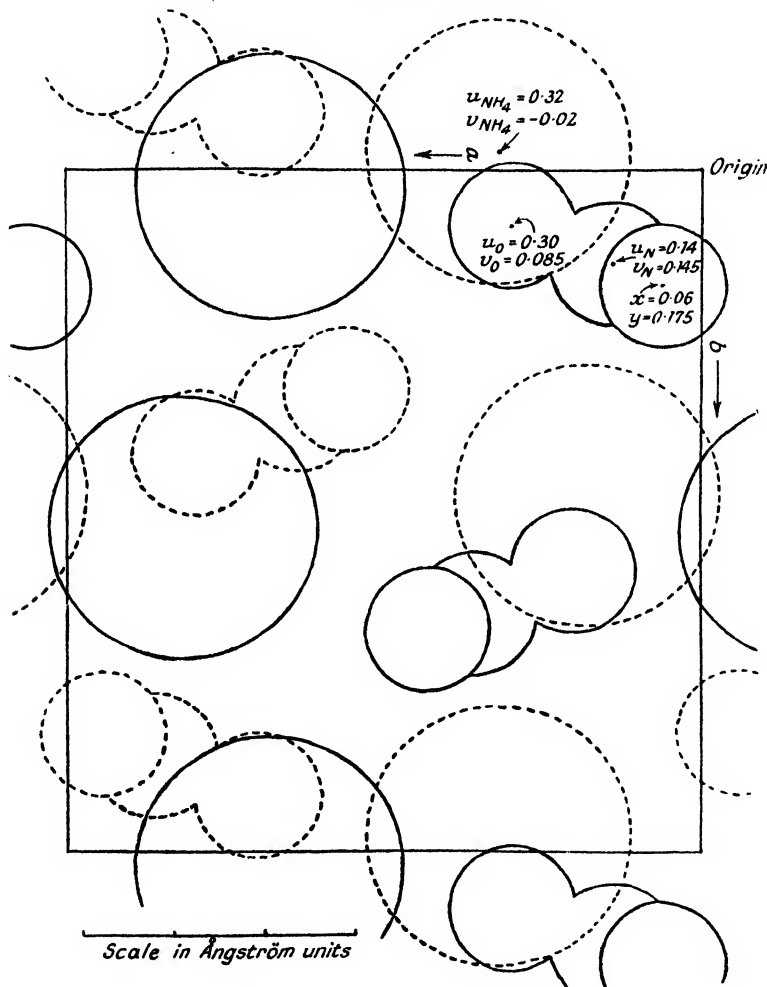

of the nitrate ion all being supposed to have the same atomic scattering factors with $f_0(O) = f_0(N) = 8$. Col. 4 gives the factor $L = (1 + \cos^2 2\theta) \sin 2\theta$ by which F^2 is converted into the intensity I , recorded in col. 5. Cols. 6 and 7 record the intensities observed and calculated by Hendricks *et al.* Table III contains the absorption corrections where applied; these were calculated from the lengths of the paths of the X-ray beam through the crystals and the mass absorption coefficients recorded in the "International Tables for the Determination of Crystal Structures," 1933, Vol. II, p. 577. Apart from this, Tables III and IV will be readily understood by comparison with Table II.

It will be seen that our observed and calculated results are in better agreement than those of Hendricks, Posnjak, and Kracek. The principle difference between the two structures is in the disposition of the nitrate ions, which in our model (Fig. 1) are more nearly parallel to the

a- than to the *b*-axis, the converse being the case with the structure reported by the Americans (Fig. 2). Our proposal would therefore lead to refractive indices $\alpha//b$, $\beta//a$, $\gamma//c$. The measured values as recorded by Hendricks, Deming, and Jefferson (*Z. Krist.*, 1933, 85, 145) are $\alpha = 1.463/a$, $\beta = 1.543/b$, and $\gamma = 1.600/c$. Our own measurements, carried out on mounted crystals of known orientation (as determined by X-rays) agree with these numerically, but we find $a//b$ and $\beta//a$. In view of the fact that the crystals are long needles with their needle zone

FIG. 2.

FIGS. 1 and 2.—Fig. 1 represents the unit cell of ammonium nitrate III deduced in this investigation, projected parallel to the *c*-axis; Fig. 2 is a similar projection of the structure of Hendricks, Posnjak, and Kracek. The unbroken and the dotted circles represent atoms located on or about reflection planes at $c = \frac{1}{2}$ and $\frac{3}{4}$, respectively. The large circles represent ammonium ions (Pauling's radius 1.48 Å.), while the groups of small circles represent the nitrate ions, and oxygens in the general positions being superimposed one on another in the projection. The radii of oxygen and nitrogen are taken as Pauling's covalent radii (0.66 Å. and 0.70 Å., respectively).

faces at or nearly at right angles, it is not surprising that the vibration directions of the fast and medium rays should have been wrongly identified. Thus the revised optical properties support our proposed ionic arrangement. In our structure the NH_4^+ ions are distant 2.7–3.2 Å. from their nearest oxygen neighbours, while in theirs the mean of nine such distances ranging from 2.75 to 3.13 Å. is 2.95 Å.

277. *The Separation of d-Fructose from Other Natural Sugars as its 2:3-4:5-Diacetone and 1:2-Monoacetone Derivatives: Observations on the Behaviour of Acetone Derivatives of Monosaccharides towards Cold Decinormal Sulphuric Acid.*

By D. J. BELL.

A simple procedure is described for the isolation of *d*-fructose from mixtures of monosaccharides as the 2:3-4:5-diacetone derivative. Glucose, mannose, xylose, and rhamnose do not interfere. The method is not applicable where galactose, arabinose, or fucose are present in quantity; in such instances a procedure leading to the isolation of 1:2-monoacetone fructose is adopted.

The diacetone derivatives of glucose, mannose, and xylose and the monoacetone derivatives of rhamnose and ribose (all understood to be derived from the furanose form of the sugars) are hydrolysed to the corresponding monoacetone compounds, or to the free sugar, by several hours' treatment with 0.1N-sulphuric acid at room temperature. On the other hand, 2:3-4:5-diacetone fructose, and the diacetone derivatives of galactose, fucose, and arabinose (all believed to have pyranose structures) resist this hydrolytic attack. 1:2-4:5-Diacetone fructose is anomalous: it behaves as if it had a furanose ring although it is generally considered to be derived from fructopyranose. Use being made of this difference in hydrolytic behaviour, a number of sugar separations are facilitated through their readily obtained acetone derivatives.

THE identification of *d*-fructose, especially in crude material of biological origin, has always presented difficulty. The only crystalline derivative hitherto employed to this end is the phenylmethylosazone (Neuberg, *Ber.*, 1902, 35, 960; Neuberg and Mandl, *Arch. Biochem.*, 1946, 11, 451). This substance is formed in variable yield; when it is isolated from mixtures its physical properties tend to be erratic, and in theory, if not in practice, it may also be formed from *d*-glucose and *d*-mannose. It is also necessary to work in relatively concentrated solutions, so the presence of large amounts of mineral matter, etc., besides other sugars, as often occur in biological extracts, complicates, or may even render impossible, isolation of the phenylmethylosazone. Work in this laboratory demanded an unequivocal means of identifying relatively small amounts (*e.g.*, 100 mg.) of *d*-fructose under conditions such as those described.

It was considered that treatment of the dried material with acetone and a suitable catalyst would provide a convenient means of separating carbohydrates (as monosaccharides) from inert material and at the same time produce derivatives which, directly or indirectly, would

lead to characterisation of the sugars, and this has proved to be the case. Irvine and Garrett (J., 1910, 97, 1283) observed that 2 : 3-4 : 5-diacetone fructose (the so-called " β "-derivative) displayed remarkable stability towards cold dilute acid, in marked contrast to the behaviour of the 1 : 2-4 : 5-isomer (" α " diacetone fructose). Ohle and Koller (Ber., 1924, 57, 1566) confirmed this finding and further noted that 1 : 2-5 : 6-diacetone glucose was, like α -diacetone fructose, unstable to cold 0.1N-sulphuric acid, both substances losing at least one isopropylidene radical by hydrolysis. Ohle and Koller further demonstrated that, although low concentration of mineral acid catalyst favoured the formation of α -diacetone fructose (cf. E. Fischer, Ber., 1895, 28, 1164; Irvine and Garrett, *loc. cit.*; Montgomery, J. Amer. Chem. Soc., 1934, 56, 419), yet increase in concentration of the catalyst led to increasing formation of the β -isomer, resulting in a series of mixed products, until, at a concentration of 4% of sulphuric acid, pure β -diacetone fructose was formed. The use of catalysts such as zinc chloride (H. O. L. Fischer and Taube, Ber., 1927, 60, 485) favours formation of the α -derivative.

In the present work the above observations have been confirmed and extended. The presence of 5% (v/v) of sulphuric acid in the acetone condensation (optimum duration, 6 hours) produces over 70% of the theoretical yield of β -diacetone fructose while diacetone glucose, under similar conditions, is formed to the extent of 50–55%. If a mixture of glucose and fructose, or sucrose itself, is treated in the above manner, the products are mainly β -diacetone fructose and diacetone glucose along with minor quantities of monoacetone derivatives. Partition of this mixture between chloroform and water leaves the "mono"-constituents in the aqueous phase. Six hours' treatment of the material obtained from the chloroform phase with 0.1N-sulphuric acid effects hydrolysis of the diacetone glucose and the α -diacetone fructose to the monoacetone derivatives; pure β -diacetone fructose is obtained by partition into chloroform. If all the "mono"-residues are brought into the dry state, recondensed with acetone, treated with dilute acid, and partitioned as before, the total yield of β -diacetone fructose may approach 80% of the theoretical.

It having been established that fructose could satisfactorily be separated from glucose, it seemed desirable to determine whether differences in hydrolytic behaviour existed among the acetone derivatives of other natural monosaccharides, and to what extent their presence might interfere with the isolation of β -diacetone fructose. The required derivatives were prepared under the conditions described above (which are not necessarily optimum for sugars other than fructose). Those compounds which are considered to be derived from the pyranose form of the parent sugar, *viz.*, the diacetone derivatives of *D*-galactose, *L*-arabinose, and *L*-fucose, all proved completely resistant to the action, for 6 hours, of 0.1N-sulphuric acid. In contrast, the furanose compounds, diacetone *D*-mannose, diacetone *D*-xylose, and monoacetone *L*-rhamnose, behaved similarly to diacetone glucose and were converted into substances which could not be extracted from water by chloroform. Crude "monoacetone *D*-ribose" (see Experimental) is hydrolysed comparatively slowly, but, although it is partitioned into chloroform, the restricted occurrence of the parent sugar is unlikely to cause difficulties. It was found practicable to isolate β -diacetone fructose from a mixture composed of 200 mg. each of *D*-fructose and six other sugars, despite the presence of both diacetone *D*-galactose and diacetone *L*-arabinose in the final product of the chloroform–water partition.

A possible explanation of the marked difference in stability towards acid exhibited by the two types of diacetone sugar may lie in the fact that in each example possessing a furanose sugar ring the labile isopropylidene radical is united through a primary alcoholic group. However, in the instance of the labile radical of α -diacetone fructose, if we assume that the hitherto accepted pyranose structure is correct, two secondary *cis*-alcoholic groups (4 and 5) are engaged. Such configurations are stable when the sugar ring is pyranose, and labile when it is furanose. The 1 : 2-monoacetone fructose derived from α -diacetone fructose is well known to possess a pyranose structure. It may be possible that α -diacetone fructose is really a derivative of fructofuranose having its isopropylidene radicals attached through positions 1 : 2 and 4 : 6, and that hydrolysis to the monoacetone derivative is accompanied by enlargement of the ring. Our present knowledge of the chemistry of the ketoses is too scanty definitely to forbid such a transformation.

If it is desired to separate fructose from sugars which form pyranose derivatives, with acetone, condensation catalysed by 0.3% (v/v) of sulphuric acid will lead to the production of α -diacetone fructose. The action of dilute acid will hydrolyse the latter to 1 : 2-monoacetone fructose which can be partitioned from chloroform into water, leaving the pyranose diacetone compounds in the organic solvent. The yield of monoacetone fructose thus obtained is good.

EXPERIMENTAL.

Evaporation of solvents was conducted below 50°, under diminished pressure. M. p.'s. are uncorrected. Measurements of optical activity were made in a 2-dm. tube. Acetone was kept, for at least 2 weeks, over calcium chloride before use.

α-Diacetone d-Fructose.—(a) *Catalyst, zinc chloride.* The method of H. O. L. Fischer and Taube (*loc. cit.*) was followed. From 2 g. of fructose, the yield (not improved by using varying amounts of catalyst) was 3.8 g., after recrystallisation from ligroin (b. p. 60–80°); m. p., 119°, $[\alpha]_D^{18}$ (water) – 161.0°; (chloroform) – 147.3°.

(b) *Catalyst, 0.3% sulphuric acid.* 5 G. of fructose were shaken with 50 ml. of dry acetone containing 0.15 ml. of concentrated sulphuric acid; after 24 hours the sugar was completely dissolved. The reaction mixture was kept for a further 24 hours, stirred with anhydrous sodium carbonate to remove acid, filtered, and evaporated. The residue was dissolved in water, the pH adjusted to 8.5–9 by addition of dilute sodium hydroxide, and the solution distilled under reduced pressure to remove mesityl oxide. The solution was then shaken with a little charcoal, filtered, and three times extracted with its own volume of chloroform. On evaporation of the dried (Na_2SO_4) extract, 5.29 g. of crystalline material were left. Recrystallised from ligroin (b. p. 60–80°), 4.79 g. (66%) of pure *α*-diacetone fructose were obtained, having m. p. 119°, $[\alpha]_D^{18}$ (chloroform) – 147.3°.

β-Diacetone Fructose.—(a) *Catalyst, 4% sulphuric acid* (cf. Ohle and Koller, *loc. cit.*). 5 G. of fructose were shaken with 50 ml. of dry acetone containing 2 ml. of sulphuric acid. The sugar dissolved rapidly and, after being kept for 3 hours, the solution was worked up in the manner described for the *α*-isomer. The crude product (3.7 g.) was crystalline; it proved, however, to consist of mixed crystals of the *α*- and the *β*-isomer which could not be separated by fractional crystallisation; m. p. ca. 80°, $[\alpha]_D^{18}$ (water) – 62.8°. (Ohle and Koller observed similar inseparable mixtures when using lower concentrations of catalyst.) This mixture corresponds to one of 25% "*α*" with 75% "*β*"; 3.2 g. were kept for 3 hours in 0.1N-sulphuric acid solution. After neutralisation of the acid with dilute sodium hydroxide, the solution was three times extracted with its own volume of chloroform. On evaporation of the solvent, 2.4 g. (75% of the mixed crystals taken) of needles, m. p. 93–94°, remained. After recrystallisation from ligroin (b. p. 60–80°), the m. p. rose to 95–96° and $[\alpha]_D^{18}$ (water) was – 33.1° (c. 7); these constants agree with those previously recorded.

(b) *Catalyst, 5% sulphuric acid.* 2.5 G. of fructose were shaken for 4 hours with 25 ml. of acetone containing 1.25 ml. of sulphuric acid, and the mixture treated as before. The chloroform phase yielded 2.7 g. (74%) of crystals, m. p. 90°, $[\alpha]_D^{18}$ (water) – 41.9°, corresponding to a mixture of 93% "*α*" with 7% "*β*".

The aqueous phase from the chloroform extraction was evaporated to dryness, and 0.5 g. of a colourless solid obtained; this was treated with 10 ml. of acetone (5% H_2SO_4) in the manner described above for 4 hours. After the customary separation by partition, 0.4 g. of crystalline diacetone fructoses was obtained, bringing the total yield to 3.1 g. 2.5 G. of this material were subjected to the action of 0.1N-sulphuric acid for 2 hours; the yield of pure *β*-diacetone fructose (m. p. 95–96°) was 2.3 g. (ca. 79%).

Ohle and Koller stated that the specific rotation (in water) of *β*-diacetone fructose varies with the concentration of the solute. That this is not the case is shown by the following observations:

Concn., g./100 ml.	7.0	3.5	1.0
$[\alpha]_D^{18}$	– 33.1°	– 33.1°	– 32.95°

The specific rotation in chloroform was also found to be – 24.8° over a range of concentrations.

The Stability of β-Diacetone Fructose towards 0.1N-Sulphuric Acid.—352 Mg. of pure *β*-diacetone fructose were dissolved in the acid, and the solution kept at room temperature for 6 hours. After the pH of the solution had been brought to about 9 by addition of sodium hydroxide, it was three times extracted with chloroform. Evaporation of the chloroform phase yielded 350 mg. (99.5%) of crystals, m. p. 95°, $[\alpha]_D^{18}$ (water) – 32.9° (c. 2.5).

Conversion of α into β-Diacetone Fructose.—1.300 G. of *α*-diacetone fructose were dissolved in 20 ml. of acetone containing 1 ml. of sulphuric acid. After being kept for 6 hours at room temperature, the product was isolated by the usual procedure. The yield of crystals was 1.202 g. (92.5%); $[\alpha]_D^{18}$ was – 32.7° (chloroform), corresponding to a mixture of 90% "*β*" with 10% "*α*". The material was therefore treated with 0.1N-sulphuric acid for 6 hours, and the *β*-diacetone fructose isolated by partition into chloroform. 1.010 G. of needles were obtained, corresponding to 93.5% of the *β*-diacetone compound estimated to be present in the product of the acetone treatment. The material had $[\alpha]_D^{18}$ (chloroform) – 24.8° (c. 5.78), and after recrystallisation from ligroin (b. p. 60–80°) melted at 95–96°.

Action of Acetone containing 5% of Sulphuric Acid on Some Monosaccharides.—The finely powdered sugar was shaken for 6 hours (unless stated to the contrary) with 20 parts (v/w) of acetone containing 5% (v/v) of the catalyst. The reaction mixture was treated as in the preparation of *α*-diacetone fructose, and the product isolated by triple chloroform extraction from water.

(a) *d*-Glucose (5 g.). Crude yield (crystalline) 4.59 g. (63%); recrystallised from ligroin (b. p. 60–80°), 3.84 g. (53%), m. p. 110°; $[\alpha]_D^{18}$ (chloroform) – 12.3° (c. 5.6).

(b) *d*-Galactose (5 g.). After 24 hours, 0.9 g. of sugar remained undissolved; yield (syrup) 3.55 g. (60%); $[\alpha]_D^{18}$ (chloroform) – 55.0° (c. 2.14), (water) – 42.8° (c. 2.77).

(c) *d*-Mannose (2 g.). 1.802 G. of crystals, m. p. 123°, were obtained. This material was pure, the m. p. not being raised by crystallisation from ethanol; $[\alpha]_D^{18}$ (methanol-water, 2:3) showed downward mutarotation, from + 7.8° to + 3.9° (const. after 24 hours) (c. 1.29). In chloroform solution (c. 5.9) similar behaviour was observed, $[\alpha]_D$ falling from + 8.7° to a constant value (24 hours) of + 5.7°.

(d) *d*-Fructose (5 g.). The crude product was treated with cold 0.1N-sulphuric acid for 6 hours. The yield of pure material (from ligroin, b. p. 60–80°) was 5.40 g. (75.8%), m. p. 95°, $[\alpha]_D^{18}$ (chloroform) – 24.6° (c. 3.9).

(e) *l*-Fucose. 535 Mg. yielded 670 mg. (84%) of syrup which crystallised (needles), m. p. 35–37°.

1464 The Separation of d-Fructose from Other Natural Sugars, etc.

Distillation in a high vacuum failed to raise the m. p. Recrystallisation was readily effected from 50% aqueous methanol, yielding needles, m. p. 35–36°, $[\alpha]_D^{25}$ (chloroform) + 53.6° (c. 2.35).

(f) l-Arabinose (5 g.). Crude yield, crystalline, 6.59 g. (86%). Recrystallised from water, the substance, 4.80 g. (66.5%) had m. p. 41–42° and $[\alpha]_D^{25}$ (water) + 5.4° (c. 2.88), (chloroform) – 13.2° (c. 4.2).

(g) d-Xylose (2 g.). Crude yield (syrup) 1.82 g. (59.5%), $[\alpha]_D^{25}$ (water) + 13.0° (c. 1.32), (chloroform) + 5.0° (c. 2.68).

(h) d-Ribose. 270 Mg. yielded 129 mg. of a syrupy "monoacetone" condensation product.

Although a reasonable yield is in each instance obtainable by the above procedure, it is emphasised that, the preparation of β -diacetone fructose excepted, methods already described in the literature may for individual examples prove superior.

Recovery of Acetone Sugars after Treatment with Cold 0.1N-Sulphuric Acid.—Weighed amounts of the sugars were condensed with acetone (5% sulphuric acid) for 6 hours, and the products, isolated by the procedure described above, subjected to the action of 0.1N-sulphuric acid at room temperature for the times stated. Any material extractable by chloroform was then recovered and weighed. The findings are tabulated below:

Sugar.	Wt. used, mg.	Hrs. in acid:		Yield (%) of sugar taken.		Diacetone cpd. resistant to 0.1N-H ₂ SO ₄ , %.
		2.	6.	2.	6.	
d-Glucose	500	82	0	11.3	0	0
d-Mannose	500	80	0	11.0	0	0
d-Xylose	500	49	0	6.4	0	0
l-Rhamnose	500	55 *	0	8.9 *	0	0
d-Ribose.....	270	—	50 †	—	14.6 *	—
d-Galactose	390	345	340	68	65	95.6
l-Arabinose	500	663	663	86.4	86.4	100
l-Fucose	535	670	633	84.2	83.3	94.4

* Monoacetone derivatives.

† This material is probably a mixture of 2 : 3-monoacetone ribofuranose with the anhydro-derivative described by Levene and Stiller (*J. Biol. Chem.*, 1933, **102**, 187); sufficient material was not available for accurate investigation.

Monoacetone d-ribose is considered by Levene and Stiller (*loc. cit.*) to be substituted in positions 2 and 3 and to have a furanose ring; the behaviour of the crude product described above is intermediate between those compounds which have furanose rings and those resistant substances where the sugar ring is pyranose. It is possible that the acid-resistant portion is the anhydro-fraction of the crude material.

Fission of Sucrose : Separation of d-Fructose from d-Glucose.—1.00 G. of finely powdered sucrose was shaken for 6 hours with 20 ml. of dry acetone containing 1.25 ml. of sulphuric acid. The crude product, isolated by the customary procedure, was a crystalline mixture of diacetone glucose with the two diacetone fructoses. Treatment of this with 0.1N-sulphuric acid for 6 hours, followed by partition between chloroform and water, yielded 0.66 g. (86.8%) of crystalline material which, after recrystallisation from ligroin (b. p. 60–80°), weighed 0.593 g. (78%) and had m. p. 95° and $[\alpha]_D^{25}$ (chloroform) – 24.7° (c. 5.2).

Separation of β -Diacetone Fructose from a Mixture of Seven Monosaccharides.—A mixture of 200 mg. of each of the following sugars was treated in the manner described for the foregoing experiment: d-glucose, d-galactose, d-mannose, l-arabinose, d-xylose, l-rhamnose, and d-fructose. After the acid treatment the crude product became partly crystalline. As it weighed 450 mg. it obviously contained diacetone galactose and diacetone arabinose as well as β -diacetone fructose. The crystals were drained on porous tile, after trituration with ice-cold ligroin (b. p. below 40°); recrystallisation in the usual way yielded 90 mg. of β -diacetone fructose, m. p. 95° alone or mixed with authentic substance.

Separation of Fructose, as the 1 : 2-Monoacetone Derivative, from a Sugar yielding an Acid-stable Diacetone Derivative.—If the mixture of sugars is condensed with acetone containing 0.3% of sulphuric acid as catalyst, as noted above, the fructose yields the acid-unstable α -diacetone derivative. (Galactose and arabinose yield 11% and 90% of their respective diacetone derivatives.) A mixture of 1.008 g. of α -diacetone fructose with 1.046 g. of diacetone galactose was kept in 0.1N-sulphuric acid solution for 4 hours at 16°. The unchanged diacetone galactose was extracted with chloroform, as in preceding experiments. The aqueous phase was made alkaline (phenolphthalein) with potassium hydrogen carbonate and heated at 100° for 30 minutes to destroy traces of reducing sugar. The solution was then evaporated, and the solid residue extracted three times with 50 ml. portions of boiling, dry ethyl acetate. On evaporation of this extract, 0.76 g. (89%) of nearly pure, crystalline 1 : 2-monoacetone d-fructose was obtained; m. p. 119°, $[\alpha]_D^{25}$ (water) – 158.8°. After recrystallisation from dry ethyl acetate, the m. p. rose to 121–122° and $[\alpha]_D^{25}$ (water) was – 159.4° (c. 3.4). From the chloroform phase of the partition 0.981 g. of diacetone d-galactose was recovered after evaporation of the solvent.

The author is grateful to Professor A. R. Todd and Dr. E. G. V. Percival for gifts of d-ribose and l-fucose. The financial support of the Agricultural Research Council is thankfully acknowledged.

278. The Reaction between Trialkyl Phosphites and Alkyl Halides.

By A. H. FORD-MOORE and J. HOWARTH WILLIAMS.

The rearrangement of trialkyl phosphites (Arbusov) has been extended so as to afford a simple method for preparing the dialkyl esters of alkyl- and halo-alkyl-phosphonic acids. When the halogen (bromine) atom in diethyl halogeno-alkylphosphonates is in the β -position to the phosphorus, hydrogen bromide is readily lost, giving dialkyl alkylenephosphonates.

THE Arbusov rearrangement in its simplest form (*Chem. Zentr.*, 1906, II, 1640) consists of the isomerisation of a trialkyl phosphite to a dialkyl alkylphosphonate (in 95% yield) by warming it with the corresponding alkyl iodide. Arbusov and Kushkova (*J. Gen. Chem. Russia*, 1936, 6, 283) extended the reaction to methylene iodide and found that when this compound was heated with triethyl phosphite (I), diethyl iodomethylphosphonate could be isolated from the reaction mixture.

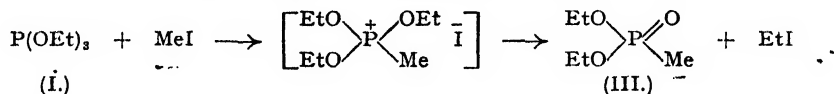

Later, Kosolapoff (*J. Amer. Chem. Soc.*, 1944, 66, 1511) reinvestigated the reaction between (I) and butyl bromide, hexyl bromide, ethylene bromide, and trimethylene bromide. He found that when the first three bromides were heated with (I), ethyl bromide was eliminated and some diethyl ethylphosphonate (II) formed. He was unable to isolate any other product of the reaction. With trimethylene bromide, he obtained some tetraethyl trimethylenediphosphonate and diethyl 3-bromopropylphosphonate, the latter as the free acid after hydrolysis.

In our hands, the Arbusov rearrangement was found to be of much wider application and can be used for preparing several series of compounds. In all cases except one (in which triisopropyl phosphite was used), the reaction was carried out with (I).

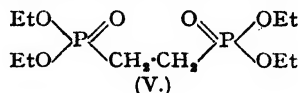

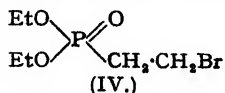

When (I) is warmed with an equimolar quantity of methyl iodide for a short time, a vigorous reaction sets in, and, on fractionation of the product, almost quantitative yields of ethyl iodide and diethyl methylphosphonate (III) are obtained. The reaction between methyl iodide and triisopropyl phosphite proceeds even more easily, the products being isopropyl iodide and diisopropyl methylphosphonate.

The interaction of (I) and ethylene bromide was next examined. If the reaction is carried out under reflux, the mixture on fractionation gives ethyl bromide, a considerable amount of (II), and a high boiling residue.

The reaction between (I) and methyl iodide gives strong support to the suggestion that the rearrangement takes place through the formation of an unstable phosphonium halide. In this particular case, the larger radical is eliminated as halide:

It seemed probable, therefore, that, in the reaction between (I) and ethylene bromide, if the ethyl bromide were allowed to escape, the amount of high-boiling residue formed would increase at the expense of the (II). This was found to be so. When the reaction was carried out under a column so that the ethyl bromide distilled out as fast as it was formed, the residue of high-boiling material was considerably greater. This, on further distillation at 1–2 mm., was found to be a mixture of diethyl 2-bromoethylphosphonate (IV) and tetraethyl ethylene-

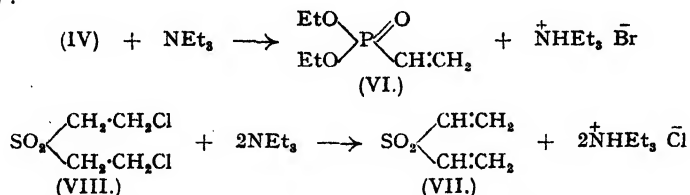

1 : 2-diphosphonate (V). Contrary to the observation of Kosolapoff (*loc. cit.*), they both appear to distil at this pressure without decomposition.

This reaction can be extended to primary alkyl bromides. With *n*-hexyl bromide or higher homologues, the reaction proceeds very smoothly giving ethyl bromide and a small amount of (II), most of the product consisting of the diethyl alkylphosphonate, isolated by distillation in a vacuum. The reaction of (I) with *n*-amyl bromide goes less easily; with *n*-butyl bromide and isoamyl bromide, it takes place very sluggishly; ethyl bromide is slowly evolved, a considerable amount of (II) is formed, and the yield of alkylphosphonate is poor. No reaction between secondary bromides, such as cyclohexyl bromide and 2-bromo-octane, and (I) takes place.

1466 The Reaction between Trialkyl Phosphites and Alkyl Halides.

When methylene bromide is used, the reaction goes slowly and a poor yield of tetraethyl methylenediphosphonate results, the bromomethylphosphonic ester being almost entirely absent. No difficulty is experienced in obtaining the methylenediphosphonate when methylene iodide is used in place of the bromide, the iodomethylphosphonic ester being formed simultaneously (cf. Arbusov and Kushkova, *loc. cit.*). With trimethylene bromide, we had no difficulty in obtaining tetraethyl trimethylenediphosphonate, but we were unable to prepare the bromopropylphosphonate either pure or in any quantity.

(IV) undergoes an interesting reaction on treatment with triethylamine in dry benzene. Triethylamine hydrobromide is formed, and diethyl vinylphosphonate (VI) can be isolated from the residue by distillation under reduced pressure. This reaction recalls the preparation of divinyl sulphone (VII) from 2 : 2'-dichlorodiethyl sulphone (VIII) (Alexander and McCombie, *J.*, 1931, 1913) :

Unlike (VII), which reacts with thiophenol with evolution of heat [to give 2 : 2'-bis(phenylthioethyl) sulphone], no reaction takes place between thiophenol and (VI).

Since secondary bromides do not enter into this reaction, we hoped to prepare diethyl 2-bromopropylphosphonate (IX) by the interaction of propylene bromide and (I); (IX) should lose HBr on treatment with triethylamine to give diethyl propenylphosphonate (X) :

When (I) and propylene bromide are heated, ethyl bromide distils but no trace of (IX) can be isolated, the product consisting of (II) together with a rather poor yield of (X).

The (I) used in these reactions was prepared by the method of McCombie, Saunders, and Stacey (*J.*, 1945, 380) who obtained it by the action of phosphorus trichloride on ethanol in ether in the presence of dimethylaniline. We found that the dimethylaniline could be replaced with advantage by diethylaniline and the ether by light petroleum (b. p. 40–60°). The diethylaniline hydrochloride formed is non-hygroscopic, a 95% recovery of the base is obtained without difficulty, and the yield of (I) is at least 85%.

EXPERIMENTAL.

Triethyl Phosphite (I).—This, prepared in 87–92% yield by the method of McCombie, Saunders, and Stacey (*loc. cit.*) but with light petroleum (b. p. 40–60°) and diethylaniline in place of ether and dimethylaniline, had the following constants: b. p. 52°/14 mm., 57°5'/19 mm. (McCombie, Saunders, and Stacey give b. p. 48°/12.5 mm.), d_{15}^{20} 0.963, n_D^{20} 1.4140.

Triisopropyl phosphite was prepared similarly, but owing to the closeness of its b. p. to that of diethylaniline, an equivalent amount of pyridine, or, better, triethylamine was used in place of the former.

Diethyl Methylphosphonate (III).—(I) (55 g.) and methyl iodide (50 g.) were refluxed gently for 2 hours on a steam-bath. On distillation at ordinary pressure, ethyl iodide (50 g.) was recovered. The residue distilled in a vacuum gave **diethyl methylphosphonate** (52.5 g.; 95%), b. p. 64–65°/2 mm., n_D^{20} 1.4120 (Found: C, 39.18; H, 8.83. $\text{C}_6\text{H}_{13}\text{O}_3\text{P}$ requires C, 39.47; H, 8.55%).

Diisopropyl methylphosphonate was obtained similarly from triisopropyl phosphite and methyl iodide in 95% yield. The reaction is vigorous and the conversion complete within a few minutes; b. p. 66°/3 mm., n_D^{20} 1.4120 (Found: C, 45.95; H, 9.53. $\text{C}_7\text{H}_{15}\text{O}_3\text{P}$ requires C, 46.66; H, 9.44%).

The Diethyl Alkylphosphonates.—Diethyl ethylphosphonate (II) was prepared in 95% yield by the method of Arbusov (*loc. cit.*) from (I) and ethyl iodide; b. p. 62°/2 mm., d_{15}^{20} 1.032, n_D^{15} 1.4172.

Diethyl n-dodecylphosphonate. (I) (62.5 g.) and n-dodecyl bromide (94 g.) were heated under a column attached to a condenser set for distillation. At about 160°, ethyl bromide started to distil. After about 1.5 hours, ethyl bromide (31.5 g.) stopped distilling and the mixture was fractionated under reduced pressure to give: (II) (7 g.), b. p. 60–70°/3 mm.; dodecyl bromide (8 g.), b. p. 124°/1 mm.; **diethyl n-dodecylphosphonate** (73 g.), b. p. 160°/1 mm., n_D^{20} 1.4419 (Found: C, 62.86; H, 11.60. $\text{C}_{14}\text{H}_{31}\text{O}_3\text{P}$ requires C, 62.74; H, 11.51%).

The following esters were obtained similarly. **Diethyl n-butylphosphonate**, b. p. 74°/1 mm., n_D^{17} 1.4244 (Found: C, 47.40; H, 10.21. $\text{C}_8\text{H}_{19}\text{O}_3\text{P}$ requires C, 49.49; H, 9.86%). **Diethyl n-amylphosphonate**, b. p. 86°/1.5 mm., $n_D^{16.5}$ 1.4282 (Found: C, 51.12; H, 10.36. $\text{C}_9\text{H}_{21}\text{O}_3\text{P}$ requires C, 51.90; H, 10.17%). **Diethyl n-hexylphosphonate**, b. p. 103°/2 mm., n_D^{17} 1.4311 (Found: C, 53.34; H, 10.58. $\text{C}_{10}\text{H}_{23}\text{O}_3\text{P}$ requires C, 54.08; H, 10.43%). **Diethyl n-heptylphosphonate**, b. p. 113°/1.9 mm., $n_D^{16.5}$

1.4325 (Found: C, 54.90; H, 10.87. $C_{11}H_{18}O_3P$ requires C, 55.90; H, 10.66%). *Diethyl n-octylphosphonate*, b. p. $119^\circ/1.2$ mm., n_D^{20} 1.4360 (Found: C, 57.54; H, 10.88. $C_{13}H_{27}O_3P$ requires C, 57.59; H, 10.88%). *Diethyl 3-methyl-n-butyl-1-phosphonate*, b. p. $75^\circ/0.8$ mm., n_D^{20} 1.4266 (Found: C, 51.54; H, 10.26. $C_8H_{17}O_3P$ requires C, 51.90; H, 10.17%).

Diethyl 2-bromoethylphosphonate (IV). (I) (83 g. = 0.5 mol.) and ethylene bromide (141 g. = 0.75 mol.) were heated as in the preparation of the dodecylphosphonic ester described above. The reaction was complete in about two hours, 48 g. of ethyl bromide having distilled. The residue on fractionation under reduced pressure gave the following products: recovered ethylene bromide, 77 g.; (II) b. p. $60-70^\circ/3$ mm., 15 g.; *diethyl bromoethylphosphonate*, b. p. $101^\circ/0.8$ mm., n_D^{20} 1.4600, 48.5 g. (Found: C, 29.71; H, 5.96. $C_8H_{14}O_3BrP$ requires C, 29.40; H, 5.76%); tetraethyl ethylenediphosphonate, (g.v.), b. p. $167^\circ/1$ mm.

Diethyl iodomethylphosphonate, b. p. $101^\circ/0.7$ mm., n_D^{20} 1.4975 (Found: C, 21.94; H, 4.58. Calc. for $C_8H_{13}O_3IP$: C, 21.60; H, 4.36%) and *tetraethyl methylenediphosphonate*, b. p. $143^\circ/1.5$ mm., n_D^{20} 1.4312 (Found: C, 35.68; H, 7.67. $C_8H_{12}O_6P_2$ requires C, 37.51; H, 7.70%) were obtained similarly by substituting methylene iodide for ethylene bromide. Tetraethyl methylenediphosphonate was also obtained by using methylene bromide in place of methylene iodide, but in poor yield; the expected diethyl bromomethylphosphonate was almost entirely absent.

Diethyl vinylphosphonate (VI). (IV) (48.5 g.), triethylamine (22 g. = 30 c.c.), and benzene (70 c.c.) were refluxed for 1 hour. After standing overnight, the triethylamine hydrobromide was filtered off, the benzene distilled from the filtrate, and the residue fractionated under reduced pressure. *Diethyl vinylphosphonate* (26 g.), n_D^{20} 1.4320, distilled at $63^\circ/2.5$ mm. (Found: C, 43.54; H, 8.37. $C_8H_{13}O_3P$ requires C, 43.88; H, 7.98%).

Tetraethyl ethylenediphosphonate (V). (I) (157 g.) and ethylene bromide (100 g. = 47 c.c.) were allowed to react as in the preparation of (IV) and the product was worked up similarly. Ethyl bromide (75 g.) distilled during the reaction, and the residue gave the following fractions: (II), b. p. $55-60^\circ/2$ mm., 55 g.; (IV), b. p. $99-115^\circ/1$ mm., 18 g.; *tetraethyl ethylenediphosphonate*, b. p. $167^\circ/1$ mm. ($180^\circ/2.5$ mm.), 71 g., n_D^{20} 1.4425 (Found: C, 39.26; H, 7.96. $C_{10}H_{24}O_6P_2$ requires C, 39.73; H, 8.00%).

Tetraethyl trimethylenediphosphonate. This was made similarly from (I) and trimethylene bromide; it had b. p. $175^\circ/0.8$ mm., n_D^{20} 1.4508 (Found: C, 40.34; H, 8.18. Calc. for $C_{11}H_{26}O_6P_2$: C, 39.73, H, 8.29%).

When (I) and 1:2-dibromopropane were similarly treated, no diethyl 2-bromopropylphosphonate could be isolated. After repeated fractionation under reduced pressure, the product was *diethyl propenylphosphonate* (X), b. p. $78-81^\circ/2$ mm., n_D^{20} 1.4320 (Found: C, 46.60; H, 8.79. $C_7H_{14}O_3P$ requires C, 47.19; H, 8.49%).

The microanalyses were carried out by Mr. W. Brown. The consistently low values found for carbon are probably due to the difficulty in effecting the complete combustion of these substances.

279. Lanosterol. Part IV. Hydrocarbons formed by the Action of Dehydrating Agents.

By CHARLES DORÉE, JAMES F. MCGHIE, and FREDERICK KURZER.

Phosphorus oxychloride and pentachloride have proved effective dehydrating agents in the lanosterol group. Thus, dihydrolanosterol, according to the reagent and conditions employed, yields two isomeric hydrocarbons of the formula $C_{30}H_{50}$, α -lanostadiene, and isolanostadiene, respectively. Dihydroagnosterol (γ -lanosterol) and other members of this series are dehydrated with equal facility to the corresponding hydrocarbons. A new alternative method for the preparation of α -lanostene (Ruzicka *et al.*, *Helv. Chim. Acta*, 1944, 27, 479) is also described, and the relationship between these hydrocarbons is discussed in connection with the position of the unsaturated centres in the molecule.

THE experimental facts established in previous researches in regard to lanosterol are the formula, $C_{30}H_{50}O$, and the presence of one secondary hydroxyl group and two double bonds—one reactive and one inert—in a tetracyclic, triterpenoid nucleus, with a side-chain of at least four carbon atoms terminating in an isopropylidene group, in which the reactive double bond is incorporated. It was known that the lanosterol fraction obtained from wool-grease contained approximately 10% of the analogous triply unsaturated alcohol agnosterol, $C_{30}H_{48}O$. More recently, Ruzicka *et al.* (*Helv. Chim. Acta*, 1944, 27, 479; *ibid.*, 1945, 28, 759) have recognized the presence of both dihydrolanosterol and dihydroagnosterol, and lanosterol has been shown to be identical with the cryptosterol of yeast. The agnosterol compounds can be removed by exhaustive crystallization, leaving a non-separable mixture of lanosterol and its dihydro-derivative, which hitherto has been described as lanosterol. Lanosterol (cryptosterol) has been obtained from this by oxidation, followed by separation and reduction of the ketones. The non-separable mixture, on hydrogenation, yields pure dihydrolanosterol which is suitable for experimental work.

An examination of the hydrocarbons derived from lanosterol and its analogues was undertaken to obtain evidence of the relationship between lanosterol and other tetracyclic triterpenes, and to make available new compounds for structural investigation. The fully saturated parent hydrocarbon lanostane has not yet been obtained. Lanostene, corresponding to lanosterol, and hydrocarbons derived from dihydrolanosterol, dihydroagnosterol (γ -lanosterol), and isodihydrolanosterol have been prepared by Ruzicka *et al.* (*loc. cit.*). The procedure employed in each case was to prepare the ketone, the semicarbazone of which was reduced, according to the Wolff-Kishner method, with sodium and ethanol under pressure. A simple and convenient modification has now been found in the direct reduction of ketone to hydrocarbon, using a modified form of the Clemmensen reaction with amalgamated zinc and hydrochloric acid. Under the conditions of experiment the hydrochloric acid does not cause bond-movement, and good yields of the desired hydrocarbons are readily obtained.

A systematic examination of the action of dehydrating agents on dihydrolanosterol has resulted in a new approach to hydrocarbons containing an additional double bond. In the dehydrations studied, the unsaturated linkage would be introduced by the removal of the hydroxyl group and the hydrogen of an adjacent carbon atom of the ring system. Provided that bond-movement does not take place, therefore, the location of the newly formed double bond is limited with great probability to a single position in the ring containing the hydroxyl group.

Most of the dehydrating agents that have been successfully employed in the case of the sterols and triterpenes were found unsuitable for dehydration in the lanosterol series. Anhydrous copper sulphate in xylene, activated alumina at temperatures up to 250°, *p*-toluenesulphonyl chloride in boiling pyridine, and acetic anhydride-sulphuric acid mixtures failed to yield products of dehydration. On the other hand, the halides and oxyhalides of phosphorus, particularly the oxychloride and pentachloride, proved highly satisfactory, giving hydrocarbons smoothly and in excellent yield.

Phosphorus oxychloride, applied by Heilbron (*J.*, 1935, 1223) in the conversion of lumisterol into lumistatetraene, when acting on dihydrolanosterol under analogous conditions gave a non-homogeneous reaction product from which α -lanostadiene was isolated. γ -Lanosterol (dihydroagnosterol) similarly gave a trebly unsaturated hydrocarbon, γ -lanostatriene. α -Lanostadiene showed no characteristic absorption in the ultra-violet, but γ -lanostatriene gave absorption maxima almost identical with those of γ -lanosteryl acetate (Bellamy and Dorée, *J.*, 1941, 178), indicating that the system of conjugated double bonds is still present. The newly formed unsaturated linkage is remote from this system, as the characteristic absorption curve is not altered, though the intensities are higher in the case of the hydrocarbon, as shown by the following measurements:

	$\lambda_{\max.}$	$E_{1\text{ cm.}}^{1\%}$	$\lambda_{\max.}$	$E_{1\text{ cm.}}^{1\%}$	$\lambda_{\max.}$	$E_{1\text{ cm.}}^{1\%}$
γ -Lanosteryl acetate	238	300	245	380	250	250
γ -Lanostatriene	237	400	243	440	254	320

Lanostadiene has an increased reactivity due to the additional double bond which, unlike the inert double bond in dihydrolanosterol, shows a reactivity approaching that of an ethylenic linkage. Its probable location in the terminal ring of the triterpene molecule, already suggested by its mode of formation, is supported by the properties of the hydrocarbon. Thus, α -lanostadiene readily adds two atoms of hydrogen in the presence of contact catalysts forming α -lanostene, which is identical with Ruzicka's "dihydrolanostene", obtained by Wolff-Kishner reduction of dihydrolanostenone semicarbazone. Similarly, α -lanostene rapidly absorbs two atoms of bromine: the addition product is highly labile, however, and decomposes at once forming a halogen-free compound, provisionally designated isomer X. Lanostadiene is readily isomerized by hydrogen chloride yielding β -lanostadiene, and it can be dehydrogenated to yield products of still higher unsaturation. The action of either selenium dioxide in anhydrous ethanol or *N*-bromosuccinimide afford excellent yields of α -lanostatriene. This triene shows no absorption in the ultra-violet, indicating the absence of a system of conjugated double bonds, and its non-identity with γ -lanostatriene.

Opening of the terminal ring of α -lanostadiene by controlled oxidative fission under various conditions has been attempted, but no crystallisable substances have so far been isolated from the large yields of acidic reaction products obtained.

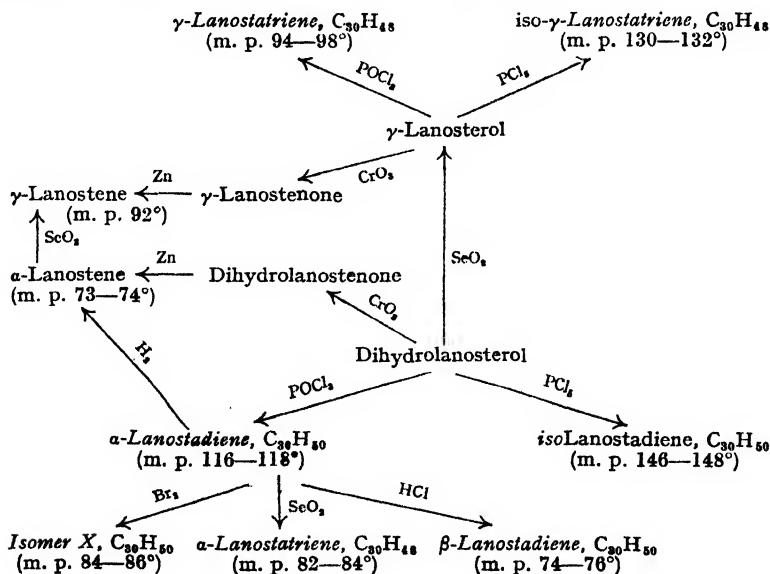

Phosphorus pentachloride has also proved a useful dehydrating reagent. α -Amyranonol, for example, in light petroleum solution is converted into α -amyradienone (Spring and Vickerstaff, *J.*, 1937, 251), while 3(β)-acetoxysterol-7- β -ol can be similarly dehydrated using the reagent in the presence of calcium carbonate in anhydrous media (Wintersteiner and

Moore, J. *Amer. Chem. Soc.*, 1943, **65**, 1507). Phosphorus pentachloride, acting on dihydrolanosterol in boiling light petroleum solution, gave excellent yields of a doubly unsaturated hydrocarbon, *isolanostadiene*. Wieland, when dehydrating dihydrocryptosterol by high vacuum distillation with boron trioxide at 350° (Wieland and Joost, *Annalen*, 1941, **546**, 119) obtained a cryptostadiene, $C_{30}H_{50}$. Since the identity of lanosterol and cryptosterol has been established by Ruzicka *et al.* (*Helv. Chim. Acta*, 1945, **28**, 759) and by ourselves, there seems little doubt that *isolanostadiene* is identical with Wieland's cryptostadiene.

isoLanostadiene and α -lanostadiene, prepared from dihydrolanosterol by the action of phosphorus pentachloride and oxychloride respectively, are isomeric. Unlike α -lanostadiene, *isolanostadiene* does not undergo hydrogenation, does not readily absorb bromine, and is considerably more resistant to chromic acid oxidation. The double bond in *isolanostadiene* is therefore far less reactive than that in α -lanostadiene, and its absence from the six-membered terminal ring (presumably owing to bond movement) can be assumed. This view is supported by spectrometric evidence. While α -lanostadiene is transparent over the spectral range in the ultra-violet, *isolanostadiene* shows a distinct absorption maximum at 235 m μ , suggesting the presence of a system of conjugated double bonds and consequently the close proximity of the centres of unsaturation. If the isomerism of the two products, however, was entirely due to the migration of the reactive double bond of α -lanostadiene under the influence of hydrochloric acid, α -lanostadiene should be readily convertible into the *iso*-compound by treatment with anhydrous hydrogen chloride. As already mentioned, however, α -lanostadiene when treated with either hydrogen chloride or phosphorus pentachloride does not yield *isolanostadiene*, but an entirely new isomer, β -lanostadiene. The observed facts can therefore not be accounted for by a consideration of geometrical isomerism alone. A retropinacoline rearrangement of the type recently described by Ruzicka *et al.* (*Helv. Chim. Acta*, 1945, **28**, 767, 942, 1628; 1946, **29**, 210), occurring when α -amyranonol, lupeanol, and oleanolic acid lactone are treated with phosphorus pentachloride, may possibly take place in the analogous formation of *isolanostadiene*. Experiments to obtain further information on the nature of these isomers are in progress.

Phosphorus pentachloride has proved equally satisfactory in the dehydration of related compounds. When applied to γ -lanosterol (dihydroagnosterol), for example, the procedure furnishes good yields of *iso*- γ -lanostatriene.

The relationships of these hydrocarbons are shown in the scheme below :

EXPERIMENTAL.

Melting points are uncorrected. The rotation measurements, for which the authors are indebted to Mr. H. Heath, were made in chloroform solution at 15°.

α -Lanostene ("Dihydrolanostenone").—A hot solution of dihydrolanostenone (5 g.; 1 mol.) in glacial acetic acid (150 ml.) was added to amalgamated zinc filings (40 g.; 50 mols.) and the mixture boiled. On

addition of concentrated hydrochloric acid (40 ml.; 30 mols.) vigorous reaction took place, and refluxing was continued for 1½ hours. The clear acetic acid solution was poured into water (600 ml.) and the crude dihydrolanostene, separating as a white flocculent precipitate, isolated by extraction with ether. The extracts were washed with sodium hydroxide solution and with water until neutral, and the colourless oily residue obtained on removal of the solvent further purified by filtration of its petroleum solution through alumina. After 3 recrystallisations from chloroform-methyl alcohol (1:5), α -lanostene (2–2.5 g.), m. p. 73–74°, $[\alpha]_D + 66.2^\circ$ (c, 0.90), was obtained in lustrous plates (Found: C, 87.58; H, 12.40. Calc. for $C_{30}H_{52}$: C, 87.38; H, 12.62%).

γ -Lanostene.—(a) γ -Lanostenone, when treated with amalgamated zinc as described above, gave 40–50% yields of γ -lanostene, forming shining plates, m. p. 89–91°, $[\alpha]_D + 77^\circ$ (c, 1.04) (Found: C, 87.99; H, 12.05. Calc. for $C_{30}H_{50}$: C, 87.81; H, 12.19%).

(b) A solution of dihydrolanostene (3 g.; 1 mol.) was refluxed with excess of selenium dioxide (3 g.; 4 mols.) in glacial acetic acid (50 ml.) for 2 hours. The separated selenium was removed, and the filtrate deposited crystalline γ -lanostene on cooling and standing. After two recrystallisations from chloroform-ethyl acetate-methyl alcohol (1:1:4), pure γ -lanostene, m. p. 90–92°, was obtained.

α -Lanostadiene.—To a solution of dihydrolanosterol (10 g.; 1 mol.) in pyridine (100 ml.) excess of phosphorus oxychloride (15 ml.; 7 mols.) was added slowly with shaking. The temperature of the mixture rose sharply to 80°. After being heated on the steam-bath for 1½ hours, the whole was boiled gently for 3 minutes and allowed to cool to room temperature. The dark brown liquid was then slowly treated with water under cooling; the crude reaction product then appeared in suspension. After repeated extraction with ether, the combined extracts were shaken with concentrated hydrochloric acid to remove pyridine, followed by repeated washings with distilled water until nearly neutral. The yellow mobile oil obtained, on removal of the solvent, was taken up in light petroleum (500 ml.) and filtered through a 25 g. alumina column. A clear colourless eluate was obtained. The yellow oil remaining after distillation of the solvent was crystallised from chloroform-acetone-methyl alcohol (30, 30, and 100 ml. respectively) to give good yields (ca. 7 g.) of a white microcrystalline mass. The material melted between 95° and 112° (signs of sintering at 85°). After repeated crystallisation from chloroform-methyl alcohol, α -lanostadiene, m. p. 114–117°, was obtained in minute white needles (2.5–3 g.). From the mother liquors there resulted a further crop (3–4 g.) of inferior material. The final fractions separated as an uncrystallisable oil (1–2 g.).

α -Lanostadiene forms microcrystalline white needles, m. p. 116–118°, $[\alpha]_D + 113^\circ$ (c, 1.040), slightly Beilstein-positive, giving a brown colour with tetranitromethane. It is soluble in chloroform, ethyl acetate, and acetone, sparingly soluble in methyl alcohol and hot glacial acetic acid (Found: C, 87.73; H, 12.26. $C_{30}H_{50}$ requires C, 87.81; H, 12.19%). Lanostadiene is optically transparent in the ultra-violet. It yields no addition product in the Diels-Alder reaction, and the absence of a system of conjugated double bonds may be inferred. It is readily reduced to α -lanostene.

A solution of α -lanostadiene (2.5 g., 1 mol.) in glacial acetic acid (150 ml.) was treated with hydrogen at 100° at ordinary pressure in the presence of finely divided platinum. Absorption of hydrogen took place rapidly, a total of 115 ml. being taken up within 10 minutes (theory, 130 ml.). Shaking was continued for another 30 minutes. After removal of the platinum the filtrate was distilled in a vacuum to small bulk (20 ml.) and the crude reaction product isolated from the residue, previously diluted with water (100 ml.), by extraction with ether. The ethereal extracts were washed with sodium hydroxide solution and with water and the solvent was removed. The residual oil, after filtration of its light petroleum solution through alumina, was crystallised thrice from chloroform-ethyl acetate-methyl alcohol, when α -lanostene was obtained in minute white plates, m. p. 70–74°, $[\alpha]_D + 65.7^\circ$ (c, 0.556), showing no depression of the melting point in admixture with α -lanostene obtained by the reduction of dihydrolanostenone (Found: C, 87.62; H, 12.40%).

Isomer X.— α -Lanostadiene (3 g.; 1 mol.), dissolved in anhydrous ether (60 ml.) was treated at 0°, within 5 minutes, with the theoretical amount of bromine dissolved in anhydrous ether (3.7 ml. of 10% v/v solution; 2 g.-atoms). The bromine solution was decolourised instantaneously; after 10 minutes' standing at 0° the ether was removed under reduced pressure, the slightly fuming yellow oil taken up in light petroleum (b. p. 60–80°; 200 ml.) and purified chromatographically. After three crystallisations from ethyl acetate-acetone-methyl alcohol, a halogen-free product, isomer X, m. p. 84–86°, $[\alpha]_D + 124^\circ$ (c, 0.372), was obtained in colourless lustrous elongated plates; ultra-violet absorption spectrum showed no absorption between 230 and 500 $m\mu$ (Found: C, 87.78; H, 12.21. $C_{30}H_{50}$ requires C, 87.81; H, 12.19%).

α -Lanostatriene.—(a) α -Lanostadiene (4 g.; 1 mol.) dissolved in ethanol (350 ml.) was treated with excess of selenium dioxide (3 g.; 3 mols.) and refluxed gently for 8 hours. The solvent was removed in a vacuum, the dark brown residue taken up in ether, and freed from traces of selenium by extraction with sodium cyanide solution. The crude reaction product in light petroleum solution was filtered through a comparatively large alumina column (30 g.). The intense yellow colour of the eluate, however, was retained after two such purifications. On crystallisation of the residue from chloroform-acetone-methyl alcohol, α -lanostatriene, m. p. 82–84°, $[\alpha]_D + 138^\circ$ (c, 0.796), was obtained in pale yellow needles; no characteristic absorption between 230 and 500 $m\mu$ (Found: C, 88.12; H, 11.83. $C_{30}H_{48}$ requires C, 88.23; H, 11.76%).

(b) α -Lanostadiene (2.5 g.; 1 mol.), dissolved in anhydrous carbon tetrachloride (60 ml.), was refluxed with excess of *N*-bromosuccinimide (1.5 g.; 1.6 mols.) for 1½ hours. Hydrogen bromide was given off throughout the reaction. After cooling, the succinimide was removed, the filtrate washed until neutral and concentrated. The oily residue was purified through an alumina column, and, after three recrystallisations from chloroform-acetone-methyl alcohol, gave α -lanostatriene in lustrous needles, m. p. 82–84°, $[\alpha]_D + 138^\circ$ (c, 0.362), identical with the product obtained by selenium dioxide dehydrogenation.

β -Lanostadiene.— α -Lanostadiene (2.5 g.), dissolved in anhydrous chloroform (50 ml.), was boiled under reflux, and hydrogen chloride passed through the solution for 3 hours. The clear green liquid obtained was washed until neutral and concentrated under reduced pressure. The residual oil, after

purification through alumina of its light petroleum solution, was crystallised thrice from chloroform-acetone-methyl alcohol, when β -lanostadiene was obtained in white needles, m. p. 74–76°, $[\alpha]_D + 128^\circ$ (c, 0.806); no characteristic absorption between 230 and 500 $m\mu$ (Found: C, 87.75; H, 12.28. $C_{30}H_{50}$ requires C, 87.81; H, 12.19%).

γ -Lanostatriene.— γ -Lanosterol (3 g.; 1 mol.), dissolved in pyridine (30 ml.) was treated with excess of phosphorus oxychloride (6 ml.; 10 mols.) at 100° for 1½ hours. On isolation of the product as described under α -lanostadiene, colourless lustrous plates of γ -lanostatriene were obtained in 60% yield, m. p. 94–98°, $[\alpha]_D + 133^\circ$ (c, 0.568) (Found: C, 88.06; H, 11.93. $C_{30}H_{48}$ requires C, 88.23; H, 11.76%). Ultra-violet absorption spectrum: Maxima at 237, 243, 254 $m\mu$; ($E_{1\%}^{1cm} = 400, 440, \text{ and } 320$ respectively), giving an absorption curve practically identical with that of γ -lanosteryl acetate (J., 1941, 178).

isoLanostadiene.—Dihydrolanosterol (10 g.; 1 mol.) dissolved in light petroleum (150 ml., b. p. 60–80°), was treated with excess of phosphorus pentachloride (10 g.; 2 mols.). Reaction took place with warming, and, after 2 hours at room temperature, dehydration was completed by refluxing for 1 hour on the steam-bath. The phosphorus pentachloride dissolved rapidly, hydrogen chloride being evolved throughout the reaction. The clear liquid was allowed to cool, diluted with an equal volume of ether (200 ml.), and freed from excess of acid by several washings with water. After drying, the solution of the crude reaction product in light petroleum was filtered through alumina and the residue obtained after evaporation of the solvent crystallised three times from chloroform-methyl alcohol. Yield, 75–85%.

isoLanostadiene forms lustrous needles, m. p. 146–148°, $[\alpha]_D + 66.4^\circ$ (c, 0.950), slightly Beilstein-positive, and giving a brown colouration with tetranitromethane (Wieland and Joost, *loc. cit.*, give m. p. 141–142° for cryptostadiene). It is soluble in chloroform, acetone, and ethyl acetate, sparingly soluble in methyl alcohol; like α -lanostadiene, and in contrast to the other members of the lanosterol group, it is sparingly soluble in hot glacial acetic acid (Found: C, 87.80; H, 12.18. Calc. for $C_{30}H_{50}$: C, 87.81; H, 12.19%). Ultra-violet absorption spectrum: maximum at 235 $m\mu$.

iso- γ -Lanostatriene.— γ -Lanosterol (6 g.; 1 mol.), dissolved in light petroleum (120 ml.; b. p. 60–80°) and treated with excess of phosphorus pentachloride (6 g.; 2 mols.) as described for *isolanostadiene*, gave good yields (60%) of iso- γ -lanostatriene, m. p. 130–132°, $[\alpha]_D + 11^\circ$ (c, 1.100), in colourless lustrous plates (Found: C, 88.14; H, 12.01. $C_{30}H_{48}$ requires C, 88.23; H, 11.76). Ultra-violet absorption spectrum: maxima at 235, 242, and 251 $m\mu$ ($E_{1\%}^{1cm} = 420, 450, \text{ and } 340$ respectively). Apart from higher intensities, the absorption curve was identical with that of γ -lanosteryl acetate.

280. Aliphatic Nitro-compounds. Part I. Preparation of Nitro-olefins by Dehydration of 2-Nitro-alcohols.*

By G. D. BUCKLEY and C. W. SCAIFE.

Nitroethylene and 1- and 2-nitroprop-1-ene are obtained in good yield by heating the appropriate nitro-alcohol with phthalic anhydride. The nitro-olefins are readily polymerised by alkali and decompose on heating; 2-nitroprop-1-ene decomposes rapidly even at room temperature.

ALTHOUGH β -nitrostyrene and its analogues have long been easily accessible, it is only within the last few years that satisfactory preparative methods for the purely aliphatic nitro-olefins have been described.

Four general methods are available all of which involve 2-nitroalkyl esters as intermediates: (a) reaction of olefins with nitrogen peroxide followed by treatment of the product with alkali (Levy and Scaife, *J.*, 1946, 1100), (b) treatment of 2-nitroalkyl esters with mild alkali (Schmidt and Rutz, *Ber.*, 1928, 61, 2142; Nightingale and Janes, *J. Amer. Chem. Soc.*, 1944, 66, 352), (c) pyrolysis of 2-nitroalkyl benzoates (Blomquist, Tapp, and Johnson, *J. Amer. Chem. Soc.*, 1945, 67, 1519), and (d) distillation of the 2-nitroalkyl acetates with a trace of sodium or potassium acetate (U.S.P. 2,257,980). The first two methods are not applicable to the preparation of nitroethylene and the nitropropenes owing to the ready polymerisation of the product.

The direct dehydration of nitro-alcohols to nitro-olefins, though well known in the case of 2-nitro-1-aryl alcohols, has hitherto been effected with only one aliphatic nitro-alcohol, 2-nitroethyl alcohol, which by treatment with potassium hydrogen sulphate gave a 50% yield of nitroethylene; this, however, cannot be used for more than a few grams of material at a time (Wieland and Sakellarios, *Ber.*, 1919, 52, 898).

Attempts to dehydrate 2-nitro-*n*-propyl alcohol with phosphoric oxide, potassium hydrogen sulphate, sulphuric acid, or zinc chloride failed to give any 2-nitropropene.

When the alcohol was heated with phthalic anhydride at 170° under a short column (to hold back unchanged material) at reduced pressure, a mixture of water and 2-nitroprop-1-ene

* Patent application pending.

(50—60% yield) distilled. 2-Nitroethyl and 2-nitroisopropyl alcohol under similar conditions gave nitroethylene and 1-nitroprop-1-ene respectively in 65—70% yield. The highest yields were obtained by using equimolecular parts of phthalic anhydride and nitro-alcohol, but, as the water formed distilled from the reactants, it was possible to reduce the anhydride to as little as 10 mol. %. Substituted phthalic anhydrides were equally effective.

Nitroethylene was obtained as a pale yellow lachrymatory oil which was moderately stable to heat and light but darkened slowly on keeping. It polymerised readily on treatment with water (cf. Wicland and Sakellarios, *loc. cit.*) and violently in presence of a trace of alkali. 2-Nitroprop-1-ene (Blomquist *et al.*, *loc. cit.*) was a pale yellow lachrymatory oil which rapidly turned green and decomposed to a black tar on being kept for a few days even in the dark; no means of arresting this decomposition was discovered. It decomposed vigorously on warming to 100° to give a complex mixture of products, and polymerised readily on treatment with alkalis. 1-Nitroprop-1-ene (Levy and Scaife, *loc. cit.*) resembled the two nitro-olefins described above, but was much more stable. It was apparently unchanged after one year's storage, and was unaffected by water, but polymerised vigorously on treatment with alkali, and decomposed on attempted distillation under atmospheric pressure.

EXPERIMENTAL.

Nitroethylene.—2-Nitroethyl alcohol (100 g.) (Levy, Scaife, and Wilder-Smith, *J.*, 1946, 1096) and phthalic anhydride (180 g.) were mixed in a distillation apparatus fitted with a short fractionating column and heated by means of an oil-bath. The apparatus was evacuated to 80 mm. and the bath temperature maintained at 140—150° until the mixture was homogeneous. The bath temperature was then raised to 175° and held at 175—180° until distillation ceased. The distillate was dried (CaCl₂) and re-distilled, giving nitroethylene (55 g.; 66.5% theory) as a pale yellow oil, b. p. 38—39°/80 mm.

1-Nitroprop-1-ene.—2-Nitroisopropyl alcohol (105 g.) (Levy and Scaife, *loc. cit.*) was brought into reaction with phthalic anhydride (150 g.) at 180°/50 mm. as described above for 2-nitroethyl alcohol. 1-Nitroprop-1-ene was obtained as a pale yellow oil (58.5 g.; 67% theory), b. p. 54°/28 mm.

2-Nitroprop-1-ene.—2-Nitro-*n*-propyl alcohol (105 g.) (Vanderbilt and Hass, *Ind. Eng. Chem.*, 1940, 32, 34) was brought into reaction with phthalic anhydride (150 g.) at 175—180°/80 mm. as described above to give 2-nitroprop-1-ene as a pale yellow oil (48.5 g.; 55.5% theory), b. p. 58°/90 mm.

The authors wish to thank Dr. A. Lowe and Mr. R. H. Stanley for suggestions and assistance in carrying out this work, and Dr. N. Levy and Dr. H. A. Piggott for their interest and advice.

281. Aliphatic Nitro-compounds. Part II. Conjugated Nitro-dienes.

By G. D. BUCKLEY and (MRS.) J. L. CHARLISH.

Three conjugated nitro-dienes, *viz.*: 3-nitropenta-1 : 3-diene, 2-nitro-3-methylbuta-1 : 3-diene and 1-(1-nitrovinyl)cyclohexene have been synthesised. These compounds are very unstable, and preliminary experiments on their addition reactions have yielded no identifiable products. 1-(1-Nitrovinyl)cyclohexene readily forms a crystalline *dimeride* of unknown constitution.

IN view of the high reactivity of the α -nitro-olefins, it seemed likely that conjugated nitro-dienes, if they could be prepared, would form a useful starting point for novel synthesis. No attempt to prepare compounds of this type appears to be recorded in the literature, and it was therefore decided to apply to the problem the methods which are successful in the synthesis of the nitro-olefins.

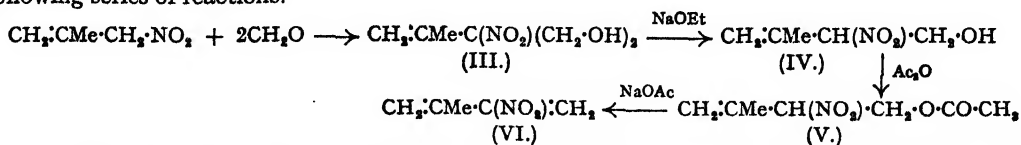

During the preparation of 2-nitroisopropyl acetate by acetylation of crude 2-nitroisopropyl alcohol formed by interaction of nitromethane and acetaldehyde (Henry, *Bull. Soc. chim.*, 1895, 13, 999), a large quantity of a high-boiling by-product was accumulated which on fractionation gave a mixture of diastereoisomerides of 3-nitro-2 : 4-diacetoxypentane (I), one of which was isolated in a pure crystalline state. On being heated with a small amount of sodium acetate, this material readily underwent fission to 3-nitropenta-1 : 3-diene (II) and acetic acid.

Like the simple nitro-olefins, the nitro-diene was a powerful lachrymator and very unstable. It decomposed to a black tar under the influence of light or heat, even in the presence of quinol, but was apparently unchanged after several weeks in the dark. It did not polymerise on treatment with alkalis but was readily polymerised by peroxides to a dark brown low-melting

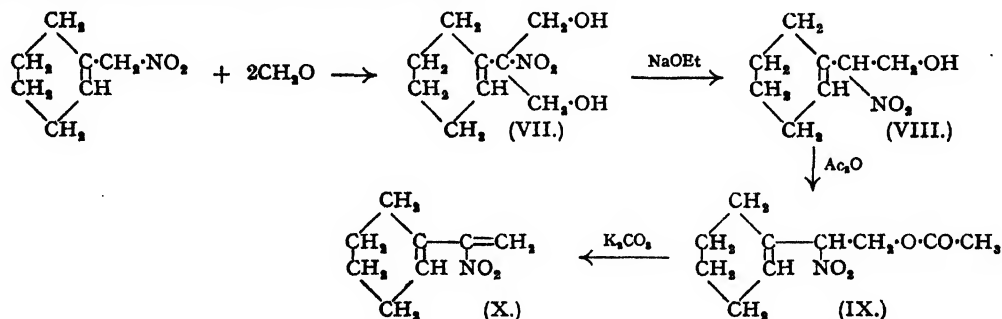

solid. It failed to react with aqueous sodium hydrogen sulphite and gave only tars on being warmed with maleic anhydride or cyclopentadiene. With bromine in carbon tetrachloride a dark oil was obtained which could not be purified; with piperidine an adduct was formed, but this was not further investigated.

2-Nitro-3-methylbuta-1:3-diene was prepared from 1-nitro-2-methylprop-2-ene by the following series of reactions.

The diol (III) on treatment with sodium ethoxide afforded the alcohol (IV) (cf. Schmidt and Wilkendorf, *Ber.*, 1919, 52, 389). Both the diol and the alcohol were difficult to purify, but for the preparation of (VI) this was immaterial, provided that the more stable acetate (V) was fractionated. The diene (VI) closely resembled the isomeric 3-nitropenta-1:3-diene in its properties but was even less stable, decomposing to a black tar on standing for a few days.

Application of these syntheses to 1-nitromethylcyclohexene gave 1-(1-nitro-2-acetoxyethyl)-cyclohexene (IX), but attempted distillation of this with sodium acetate resulted in violent decomposition. A similar result was obtained on attempting to dehydrate the alcohol (VIII) by distillation with 3-nitrophthalic anhydride.

By treating the nitro-ester (IX) in ether with potassium carbonate in presence of quinol a lachrymatory oil, presumably (X), was obtained, but this could not be purified. On standing it gave a solid which (from analysis and molecular weight) appeared to be a dimeride of (X). This product was also obtained directly if the potassium carbonate treatment was carried out in the absence of quinol. The yield was poor, but no other pure compounds were isolated. Although other new products were obtained, these could not be purified. Hydrogenation and addition of bromine to the dimer gave no definite products, and no systematic study of its reactions was attempted.

EXPERIMENTAL.

Microanalyses are by Mr. E. S. Morton. All m. ps. are uncorrected.

3-Nitro-2:4-diacetoxypentane (I).—The high-boiling residue (700 g.) from a series of preparations of 2-nitroisopropyl acetate (prepared by acetylation of the crude nitro-alcohol from acetaldehyde and nitromethane; cf. Schmidt and Rutz, *Ber.*, 1928, 61, 2142) was fractionated to give a viscous yellow oil (490 g.), b. p. 140–150°/20 mm., which partly crystallised on standing. The solid compound was collected and recrystallised from light petroleum (b. p. 100–120°), forming colourless needles (40 g.), m. p. 85–86° (Found: C, 46.6; H, 5.95; N, 6.2. $\text{C}_9\text{H}_{15}\text{O}_5\text{N}$ requires C, 46.35; H, 6.4; N, 6.0%).

The liquid fraction was apparently essentially a mixture of the two diastereoisomerides (Found: C, 46.05; H, 6.25; N, 6.6%).

3-Nitropenta-1:3-diene (II).—Crude 3-nitro-2:4-diacetoxypentane (145 g.) was stirred with anhydrous sodium acetate (1 g.) at 95–100° for 1 hour and distilled under 12 mm. The distillate was washed thrice with saturated brine, dried, and fractionated to give 3-nitropenta-1:3-diene (38 g.; 54% theory) as a pale yellow lachrymatory oil, b. p. 63–65°/13 mm. (Found: C, 53.25; H, 6.3; N, 12.35. $\text{C}_5\text{H}_9\text{O}_2\text{N}$ requires C, 53.1; H, 6.2; N, 12.4%). A considerable tarry residue remained after the distillation.

2-Nitro-1-hydroxy-3-methyl-2-hydroxymethylbut-3-ene (III).—A mixture of 1-nitro-2-methylprop-2-ene (2 g.; Levy and Scaife, in the press), ethyl acetate (6 c.c.), paraformaldehyde (1.3 g.), and 33% aqueous potassium hydroxide (1 drop) was refluxed until all the paraformaldehyde had dissolved. The solution was kept at 0° for several days, and the crystalline precipitate collected and purified by recrystallisation from ethyl acetate, giving colourless rectangular prisms of the compound, m. p. 103–104° (Found: C, 44.75; H, 6.55; N, 8.5. $\text{C}_6\text{H}_{11}\text{O}_4\text{N}$ requires C, 44.7; H, 6.8; N, 8.7%).

2-Nitro-1-hydroxy-3-methylbut-3-ene (IV).—A mixture of 1-nitro-2-methylprop-2-ene (20 g.), isopropyl alcohol (60 c.c.), paraformaldehyde (13.2 g.), and 33% aqueous potassium hydroxide (6 drops) was refluxed for 3 hours. After cooling, a solution of sodium ethoxide [from sodium (5 g.) in alcohol (50 c.c.)] was added slowly with stirring below 10°. After 1 hour's stirring at 0–10°, the precipitate was collected, dissolved in a little water, acidified with dilute hydrochloric acid below 15°, saturated with salt, and extracted with ether. The extract was dried and fractionated to give the compound as a colourless oil (5.2 g.), b. p. 113–115°/15 mm. (Found: C, 45.55; H, 7.05; N, 10.1. $C_6H_{10}O_2N$ requires C, 45.8; H, 6.85; N, 10.7%); distillation was stopped at this point owing to incipient decomposition of the residue.

2-Nitro-1-acetoxy-3-methylbut-3-ene (V).—1-Nitro-2-methylprop-2-ene (24 g.) was converted into 2-nitro-1-hydroxy-3-methylbut-3-ene as described above. After removal of the ether, the crude product was mixed with acetic anhydride (25.2 g.), heated at 100° for 1 hour, and distilled to give the compound as a colourless oil (30.2 g.), b. p. 102–104°/0.5 mm. (Found: C, 49.2; H, 6.3; N, 7.8. $C_7H_{11}O_4N$ requires C, 48.6; H, 6.35; N, 8.1%).

2-Nitro-3-methylbuta-1:3-diene (VI).—2-Nitro-1-acetoxy-3-methylbut-3-ene (30 g.) and anhydrous sodium acetate (0.1 g.) were heated under 12 mm. (oil-bath temperature 110–120°). A colourless liquid distilled, but after a short time the residue began to decompose and distillation was stopped. The distillate was washed thrice with saturated brine, dried, and distilled to give 2-nitro-3-methylbuta-1:3-diene as a pale yellow lachrymatory oil (4.7 g.), b. p. 54–57°/14 mm. (Found: N, 12.3. $C_6H_8O_2N$ requires N, 12.4%). This closely resembled 3-nitropenta-1:3-diene in all its reactions.

1-(1-Nitro-2:2'-dihydroxyisopropyl)cyclohexene (VII).—1-Nitromethylcyclohexene (7 g.; Fraser and Kon, J., 1934, 604), paraformaldehyde (3.3 g.), ethyl acetate (25 c.c.), and 33% aqueous potassium hydroxide (3 drops) were refluxed until homogeneous (2 hours). The mixture was carefully neutralised with N-hydrochloric acid and the solvent removed under reduced pressure. After being kept in a desiccator for several days, the viscous residue crystallised to a white solid, m. p. 58–61°, which was very soluble in all organic solvents except light petroleum. Attempts to purify this material were unsuccessful.

1-(1-Nitro-2-hydroxyethyl)cyclohexene (VIII).—Crude 1-(1-nitro-2:2'-dihydroxyisopropyl)cyclohexene (9 g.) was dissolved in alcohol (25 c.c.) and treated with a solution of sodium ethoxide [from sodium (1.25 g.) in alcohol (15 c.c.)] below 15°. The mixture was then cooled to 0°, and the precipitated sodium salt collected, dissolved in water, and acidified with hydrochloric acid below 15°. The product was isolated by extraction with ether, dried, and distilled to give a pale yellow oil (3 g.; 38% theory), b. p. 98–100°/0.5 mm., which solidified to a crystalline mass of 1-(1-nitro-2-hydroxyethyl)cyclohexene, m. p. 45–46° (Found: C, 56.05; H, 7.25; N, 8.1. $C_8H_{13}O_2N$ requires C, 56.15; H, 7.6; N, 8.2%).

1-(1-Nitro-2-acetoxyethyl)cyclohexene (IX).—1-Nitromethylcyclohexene (21 g.), paraformaldehyde (9.9 g.), isopropyl alcohol (45 c.c.), and 33% aqueous potassium hydroxide (0.5 c.c.) were refluxed until a clear solution was obtained. After the solution had been cooled to 0°, a solution of sodium ethoxide [from sodium (3.75 g.) in alcohol (40 c.c.)] was added during 30 minutes. After 1 hour at 0–10° with stirring, the sodium salt was collected, dissolved in water (100 c.c.), and acidified with aqueous hydrochloric acid below 10°. The precipitated oil was extracted with ether, the extract dried, and the solvent removed. The crude product was cooled in ice, treated with 98% sulphuric acid (2 drops) followed by acetic anhydride (23 g.), and the mixture stirred at 60° for 2 hours. Distillation gave a colourless oil (22.5 g.), b. p. 102–105°/1 mm. (Found: N, 6.5. $C_{10}H_{15}O_4N$ requires N, 6.55%).

1-(1-Nitrovinyl)cyclohexene (X).—1-(1-Nitro-2-acetoxyethyl)cyclohexene (15 g.), potassium carbonate (15 g.), ether (50 c.c.), and quinol (0.1 g.) were refluxed with stirring for 4 hours, cooled, and washed with water. The ethereal solution was then treated with a further 0.1 g. of quinol and dried ($CaCl_2$). The ether was removed under reduced pressure at 30°, leaving a pale yellow lachrymatory oil (9.2 g.) which decomposed on attempted distillation under 0.5 mm. (Found: N, 8.8. $C_8H_{11}O_2N$ requires N, 9.15%). The nitro-diene did not react with aqueous sodium hydrogen sulphite and did not polymerise on boiling with dilute sodium carbonate solution; on keeping, it slowly dimerised.

1-(1-Nitrovinyl)cyclohexene Dimer.—1-(1-Nitro-2-acetoxyethyl)cyclohexene (48 g.), potassium carbonate (48 g.), and ether (150 c.c.) were refluxed with stirring for 4 hours, cooled, washed with water, and dried ($CaCl_2$). The ethereal solution was allowed to evaporate at 20° and the crystals were collected (9.9 g.) and washed with light petroleum (b. p. 100–120°). Recrystallisation from light petroleum and from acetic acid gave large colourless plates of 1-(1-nitrovinyl)cyclohexene dimer, m. p. 136–137° (Found: C, 62.6; H, 7.4; N, 9.3; *M* (cryoscopic in benzene), 290. $C_{16}H_{22}O_4N_2$ requires C, 62.75; H, 7.2; N, 9.15%; *M*, 306).

The authors wish to acknowledge the interest and advice of Dr. H. A. Piggott in this work.

282. Aliphatic Nitro-compounds. Part III. Preparation of Alkyl 2-Nitroalkyl Ethers.*

By A. LAMBERT, C. W. SCAIFE, and A. E. WILDER-SMITH.

Alcohols add to α -nitro-olefins giving alkyl 2-nitroalkyl ethers, which on reduction yield amines, and on reaction with formaldehyde afford α -hydroxymethyl derivatives. 1:2-Dinitroethane (or 2-nitroethyl nitrate), 1:2-dinitropropane, and 1:2-dinitro-2-methyl-

* Cf. E.P.P. 573,872, 581,134.

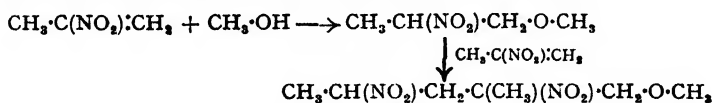

propane may be used as convenient substitutes for nitroethylene, 1-nitroprop-1-ene, and 1-nitro-2-methylprop-1-ene respectively.

THE addition of alcohols to some substituted nitro-olefins has been reported previously; thus, β -nitrostyrene (Rosenmund, *Ber.*, 1913, 46, 1034; Meisenheimer and Heim, *ibid.*, 1905, 38, 467), β -bromo- β -nitrostyrene (Thiele and Haeckel, *Annalen*, 1902, 325, 1), 2-nitro-1-(*p*-methoxyphenyl)prop-1-ene (Meisenheimer and Jochelson, *ibid.*, 1907, 355, 293), 1-bromo-1-nitrobut-1-ene and 1-bromo-1-nitropent-1-ene (Loevenich, Koch, and Pucknat, *Ber.*, 1930, 63, 636) all add alcohols in the presence of a basic catalyst to give 2-nitroalkyl ethers; benzylidene- ω -nitroacetophenone behaves similarly with boiling alcohol in the absence of a base (Wieland, *Annalen*, 1903, 328, 189; cf. Friedlander, Mahly, and Lazarus, *ibid.*, 1885, 229, 210, 234; Flürscheim, *J. pr. Chem.*, 1902, 66, 16). Since the present work was completed, the preparation of 2-nitroalkyl ethers by reaction of 1-nitrobut-1-ene and some higher nitro-olefins with sodium alkoxides has also been reported (U.S.P. 2,391,815).

The reaction of alcohols with 1 : 2-dinitro-paraffins and 2-nitroalkyl nitrates, obtained from the addition of nitrogen tetroxide to olefins (see Levy *et al.*, *J.*, 1946, 1096, 1100), and with α -nitro-olefins, was undertaken as part of a general investigation of the chemistry of these compounds and as a route to a wide variety of nitro- and amino-ethers. With boiling alcohols, 1 : 2-dinitroethane (or 2-nitroethyl nitrate) and 1 : 2-dinitropropane gave nitro-ethers as follows :

The reaction was found to be a general one, but yields diminished with increasing molecular weight of the alcohol and were lower with 2-nitroethyl nitrate than with 1 : 2-dinitroethane. Treatment of 1 : 2-dinitro-2-methylpropane with boiling alcohols gives 1-nitro-2-methylprop-1-ene which adds alcohols only in the presence of a basic catalyst. 2-Nitroprop-1-ene, 2-nitrobut-2-ene, and β -nitro- β -methylstyrene also require a basic catalyst, the highest yields being obtained by the use of an equivalent of the appropriate sodium alkoxide. In the reaction of 2-nitroprop-1-ene with sodium methoxide, in addition to methyl 2-nitro-*n*-propyl ether, some methyl 2 : 4-dinitro-2-methylamyl ether was obtained as a by-product, formed by addition of the mononitro-ether to 2-nitropropene (cf. Part VIII in this series) :

β -Nitrostyrene and sodium methoxide have been reported to give a small yield of methyl 2 : 4-dinitro-1 : 3-diphenylbutyl ether by a similar mechanism (Meisenheimer and Heim, *loc. cit.*). Nitroethylene was very reactive; even when stabilised with a small amount of phosphoric acid it added 2-methoxyethyl alcohol at ordinary temperature.

The nitro-ethers were readily hydrogenated to amines, and reaction with formaldehyde in the presence of a base gave α -hydroxymethyl derivatives.

The 2-nitrobut-2-ene used in this work was obtained from 2-nitro-3-acetoxybutane (Vanderbilt and Hass, *Ind. Eng. Chem.*, 1940, 32, 34) by heating it with sodium acetate (cf. Gen. Aniline and Film Corp., U.S.P. 2,257,980). Its structure was established by reduction with zinc and acetic acid (cf. Bouveault and Wahl, *Bull. Soc. chim.*, 1903, 29, 643) to methyl ethyl ketoxime. It is interesting that a product from the decomposition of the silver salt of nitroethane was described by Angeli and Alessandri (*Atti R. Accad. Lincei*, 1910, 19, 784; *Chem. Zentr.*, 1910, II, 731) as being probably 2-nitrobut-2-ene, but its structure was not proved.

EXPERIMENTAL.

Analyses are by Mr. E. S. Morton and Mr. A. E. Heron. All m. ps. are uncorrected.

Alkyl 2-Nitroalkyl Ethers.

(a) From 1 : 2-Dinitro-paraffins.—*Alkyl 2-nitroethyl ethers.* Methyl and ethyl 2-nitroethyl ethers were prepared by refluxing a 15% solution of 1 : 2-dinitroethane (Levy, Scaife, and Wilder-Smith, *J.*, 1946, 1096) in the appropriate alcohol for 36 hours. The excess of alcohol was distilled, and the residual crude nitro-ether distilled first in steam at 60 mm. (to avoid the unstable residue formed on distillation) and then in high vacuum. For the higher alkyl 2-nitroethyl ethers, molten 1 : 2-dinitroethane was added to the boiling alcohol, the temperature of the bath being adjusted to distil off the alkyl nitrite as formed. The nitro-ether was then isolated by fractional distillation. The compounds prepared by this method are methyl (60% yield), b. p. 38°/1 mm., 67°/12 mm.; d_{20}^{20} 1.128; n_D^{20} 1.417 (Found : C, 34.7; H, 6.9; N, 13.4. $\text{C}_2\text{H}_5\text{O}_2\text{N}$ requires C, 34.3; H, 6.7; N, 13.3%); ethyl (50% yield), b. p. 46°/1 mm.;

72°/12 mm.; d_4^{25} 1.069 (Henry, *Rec. Trav. chim.*, 1899, 18, 259, records b. p. 178°/760 mm.; d_4^{25} 1.148) (Found: C, 40.5; H, 7.5; N, 12.0. Calc. for $C_6H_{11}O_2N$: C, 40.3; H, 7.6; N, 11.8%); *n*-propyl (45% yield), b. p. 48°/0.5 mm. (Found: N, 10.3. $C_6H_{11}O_2N$ requires N, 10.5%); isopropyl, b. p. 43°/0.5 mm. (Found: N, 10.6. $C_6H_{11}O_2N$ requires N, 10.5%); *n*-butyl (27% yield), b. p. 70—72°/2 mm. (Found: N, 9.7. $C_6H_{11}O_2N$ requires N, 9.5%); and *n*-amyl 2-nitroethyl ether (39% yield), b. p. 80—82°/1.5 mm. (Found: N, 8.4. $C_7H_{13}O_2N$ requires N, 8.7%).

Methyl nitro-tert.-butyl ether. 1:2-Dinitro-2-methylpropane (29.6 g.) (Levy and Scaife, in the press) in methyl alcohol (50 c.c.) was added dropwise with stirring during 30 minutes to a solution of sodium methoxide [from sodium (9.2 g.) in methyl alcohol (200 c.c.)]. The product after dilution with water and neutralisation (acetic acid) was extracted with ether and fractionated, giving *methyl nitro-tert.-butyl ether* (5.7 g.), b. p. 75°/15 mm. (Found: C, 45.1; H, 8.3; N, 10.8. $C_6H_{11}O_2N$ requires C, 45.1; H, 8.3; N, 10.5%).

Ethyl nitro-tert.-butyl ether. 1:2-Dinitro-2-methylpropane (29.6 g.), urea (6.0 g.), and alcohol (300 c.c.) were refluxed for 15 hours. Fractionation gave *ethyl nitro-tert.-butyl ether* (4.9 g.), b. p. 75°/15 mm. (Found: C, 48.7; H, 8.7; N, 9.3. $C_6H_{13}O_2N$ requires C, 49.0; H, 8.8; N, 9.5%). Some 1-nitro-2-methylprop-1-ene, b. p. 54—58°/11 mm., was also formed, and the alcohol recovered contained acetone, formed by hydrolysis of the dinitro-paraffin.

Methyl 2-nitroisopropyl ether. 1:2-Dinitropropane (30 g.) (Levy and Scaife, *J.*, 1946, 1100) was refluxed with methyl alcohol (70 g.) for 17 hours, and the mixture fractionated, giving *methyl 2-nitroisopropyl ether* (8 g.), b. p. 36—41°/1 mm., 62°/12 mm. (Found: C, 40.9; H, 7.7; N, 11.5. $C_4H_9O_2N$ requires C, 40.3; H, 7.6; N, 11.8%).

(b) *From Nitro-olefins*.—2-Nitro-2'-methoxydiethyl ether. A mixture of nitroethylene (19.7 g.), 2-methoxyethyl alcohol (100 c.c.), and orthophosphoric acid (1 c.c.), after being kept for 1 month at ordinary temperature, was distilled to give 2-nitro-2'-methoxydiethyl ether (12.5 g.), b. p. 81—84°/0.5 mm. (Found: C, 40.3; H, 7.3; N, 9.6. $C_4H_{11}O_2N$ requires C, 40.3; H, 7.4; N, 9.4%).

Methyl nitro-tert.-butyl ether. 1-Nitro-2-methylprop-1-ene (20.2 g.) was added dropwise with stirring during 30 minutes to a solution of an equivalent of sodium methoxide [from sodium (4.6 g.) in methyl alcohol (100 c.c.)] at ordinary temperature. The product, after dilution with water and neutralisation (acetic acid), was extracted with ether and distilled, giving *methyl nitro-tert.-butyl ether* (17.3 g.), b. p. 75°/15 mm.

2-Nitro-3-methoxybutane. This was prepared as described above from 2-nitrobut-2-ene (101 g.) and sodium methoxide in methyl alcohol. 2-Nitro-3-methoxybutane was obtained as a colourless liquid, b. p. 61—63°/15 mm. (Found: C, 45.1; H, 8.3. $C_6H_{11}O_2N$ requires C, 45.1; H, 8.3%). The 2-*p*-nitrophenylazo-derivative, from the sodium salt of the nitro-ether and *p*-nitrobenzenediazonium chloride, separated in two forms; α -form, fine yellow needles from light petroleum, m. p. 91° (Found: C, 46.6; H, 5.3; N, 19.7. $C_{11}H_{14}O_4N_4$ requires C, 46.8; H, 5.0; N, 19.8%), and β -form, red prisms from light petroleum, m. p. 84° (Found: C, 46.8; H, 5.1; N, 19.3%).

Methyl 2-nitropropyl ether. This was prepared from 2-nitroprop-1-ene (27 g.; see Part I of this series) and sodium methoxide in methyl alcohol as described above. Distillation gave *methyl 2-nitropropyl ether* (15.2 g.) as a colourless oil, b. p. 61—64°/14 mm. (Found: C, 40.6; H, 7.3. $C_4H_9O_2N$ requires C, 40.3; H, 7.6%). Some methyl 2:4-dinitro-2-methylamyl ether (4.8 g.), b. p. 92.5°/0.2 mm. (see Part VIII of this series), was also obtained.

Methyl 2-nitroisopropyl ether. Interaction of 1-nitroprop-1-ene (50 g.; see Part I of this series) with sodium methoxide in methyl alcohol as described above afforded methyl 2-nitroisopropyl ether (29 g.), b. p. 62°/12 mm., identical with that obtained from 1:2-dinitropropane.

2-Nitroisopropyl *n*-butyl ether. 1-Nitroprop-1-ene (25 g.) and a solution of sodium butoxide [from sodium (6.6 g.) in *n*-butyl alcohol (120 c.c.)], brought into reaction at 0—10° and worked up in the usual way, afforded 2-nitroisopropyl *n*-butyl ether (28 g.) as a colourless oil, b. p. 98—101°/14 mm. (Found: C, 52.7; H, 9.1; N, 8.6. $C_7H_{13}O_2N$ requires C, 52.2; H, 9.3; N, 8.7%).

Nitro-tert.-butyl *n*-amyl ether. 1-Nitro-2-methylprop-1-ene (50 g.) interacted with sodium *n*-amylate as described above to afford nitro-tert.-butyl *n*-amyl ether (26 g.), b. p. 75°/1 mm. (Found: C, 57.7; H, 9.9; N, 7.2. $C_9H_{19}O_2N$ requires C, 57.2; H, 10.0; N, 7.4%).

*Methyl 2-nitro-1-phenyl-*n*-propyl ether*. A solution of β -nitro- β -methylstyrene (489 g.; cf. Alles, *J. Amer. Chem. Soc.*, 1932, 54, 271) in dioxan (150 c.c.) was added to a solution of sodium methoxide [from sodium (10.35 g.) in methyl alcohol (150 c.c.)] at 10° during $\frac{1}{2}$ hour. After being stirred for 2 hours at room temperature, the mixture was diluted with water, acidified (acetic acid), extracted with ether, and distilled. Fractionation gave *methyl 2-nitro-1-phenyl-*n*-propyl ether* (51.3 g.) as a colourless oil, b. p. 138—141°/16 mm. (Found: C, 61.6; H, 6.5; N, 7.5. $C_{10}H_{13}O_2N$ requires C, 61.5; H, 6.6; N, 7.2%).

(c) *From 2-Nitroethyl Nitrate*.—2-Nitroethyl nitrate (30 g.) was refluxed with alcohol (150 c.c.) for 8 hours. Fractionation gave ethyl 2-nitroethyl ether (15 g.), b. p. 46°/1 mm.

Interaction of Nitroalkyl Ethers with Formaldehyde.

2-Nitro-3-methoxy-*n*-propyl Alcohol.—A solution of methyl 2-nitroethyl ether (26.25 g.) in alcohol (25 c.c.) was added to a solution of sodium hydroxide (10 g.) in alcohol (150 c.c.). Paraformaldehyde (7.5 g.) was added and the mixture stirred until a homogeneous solution was obtained. The sodium salt which separated was collected, dissolved in water, acidified (acetic acid), and extracted with ether. Distillation afforded 2-nitro-3-methoxy-*n*-propyl alcohol (13.5 g.), b. p. 99—104°/0.5 mm. (Found: C, 35.2; H, 6.8; N, 10.5. $C_4H_9O_4N$ requires C, 35.6; H, 6.7; N, 10.4%). Reduction of the nitro-alcohol with Adams's platinum catalyst in alcohol at 20°/100 atm. afforded methyl 2-aminoethyl ether, isolated as the *picrate*, m. p. 148—150° (Found: C, 35.9; H, 4.1. $C_2H_5ON, C_6H_5O_2N_3$ requires C, 35.6; H, 4.0%).

2-Nitro-2-methoxymethylpropane-1:3-diol.—Methyl 2-nitroethyl ether (9.32 g.) in methyl acetate (20 c.c.) was treated with paraformaldehyde (5.32 g.) and a trace of alcoholic potassium hydroxide.

After neutralisation the product was collected and crystallised from methyl acetate–light petroleum (b. p. 40–60°), giving 2-nitro-2-methoxymethylpropane-1 : 3-diol, m. p. 82.5–83.5° (Found : C, 36.2; H, 6.8; N, 8.4. $C_6H_{11}O_3N$ requires C, 36.4; H, 6.7; N, 8.5%). Reduction of the nitro-diol with Adams's platinum catalyst in alcohol gave 2-amino-2-methoxymethylpropane-1 : 3-diol, isolated as the *picrolonate*, m. p. 219–220° (Found : N, 17.6. $C_5H_{11}O_3N, C_{10}H_{19}O_6N_4$ requires N, 17.6%).

2-Nitro-2-ethoxymethylpropane-1 : 3-diol.—This was prepared from ethyl 2-nitroethyl ether as described above for the lower homologue. The diol was obtained as an undistillable oil, identified as the *di-p-nitrobenzoyl* derivative, m. p. 240–241° (Found : C, 50.7; H, 3.7; N, 8.3. $C_{20}H_{19}O_{11}N_4$ requires C, 50.4; H, 4.0; N, 8.8%).

2-Nitro-3-methoxy-2-methyl-n-butyl Alcohol.—A mixture of 2-nitro-3-methoxybutane (40 g.), paraformaldehyde (9.1 g.), aqueous sodium hydroxide (1.5 c.c. of 40%), and methyl alcohol (80 c.c.) was stirred overnight at ordinary temperature. After neutralisation with 2N-hydrochloric acid, distillation gave 2-nitro-3-methoxy-2-methyl-n-butyl alcohol (42 g.) as a colourless oil, b. p. 110°/15 mm., 82°/0.5 mm. (Found : C, 43.5; H, 7.7; N, 8.3. $C_8H_{15}O_3N$ requires C, 44.2; H, 7.9; N, 8.6%).

2-Nitro-3-n-butoxy-n-butyl Alcohol.—2-Nitroisopropyl n-butyl ether (53 g.) was dissolved in a solution of sodium hydroxide (13.5 g.) in water (100 c.c.) at 10°, and paraformaldehyde (10 g.) was added portionwise with stirring, the temperature being allowed to rise to 32°. After 20 minutes the solution was acidified (2N-hydrochloric acid), concentrated at 40–50° under reduced pressure, filtered, and distilled, giving 2-nitro-3-n-butoxy-n-butyl alcohol (53 g.) as a pale yellow oil, b. p. 98°/0.2 mm. (Found : C, 49.9; H, 9.2; N, 7.5. $C_8H_{17}O_3N$ requires C, 50.3; H, 8.9; N, 7.3%). Reduction of the nitro-alcohol (42 g.) in methyl alcohol (700 c.c.) with Raney nickel and hydrogen at 20°/68 atms. (initial pressure) gave 2-amino-3-n-butoxy-n-butyl alcohol (27 g.) as a colourless oil, b. p. 90–92°/0.1 mm. (Found : N, 9.1. $C_8H_{17}O_2N$ requires N, 8.7%).

Alkylaminoethyl Ethers.

Methyl 2-Aminoethyl Ether.—Methyl 2-nitroethyl ether (2.0 g.) in alcohol (22 c.c.) was hydrogenated with Adams's platinum catalyst at 20°/100 atms. to give methyl 2-aminoethyl ether, isolated as the *picrate*, m. p. 148–150° (Found : C, 35.9; H, 4.1. $C_4H_9ON, C_8H_9O_3N_3$ requires C, 35.6; H, 4.0%).

Ethyl 2-aminoethyl ether, obtained in 52% yield by similar reduction of ethyl 2-nitroethyl ether, had b. p. 105°; *picrolonate*, m. p. 208–209° (decomp.) (Found : C, 47.7; H, 5.5; N, 19.6. Calc. for $C_6H_{11}ON, C_{10}H_{19}O_3N_4$: C, 47.6; H, 5.4; N, 19.8%); *picrate*, m. p. 121–123° (Found : C, 37.2; H, 4.6; N, 17.8. Calc. for $C_4H_9ON, C_8H_9O_3N_3$: C, 37.6; H, 4.4; N, 17.6%). (Meyer, *Ber.*, 1905, **38**, 3130, records m. p. 204° and 122° respectively for these derivatives.)

2-Amino-3-methoxybutane.—2-Nitro-3-methoxybutane (20 g.) was added slowly with stirring to a mixture of iron powder (3.5 g.), ferric chloride (1 g.), concentrated hydrochloric acid (10 c.c.), and water (75 c.c.) at 100°. After being stirred at 100° for 15 hours, the mixture was basified strongly with aqueous sodium hydroxide and distilled in steam. The distillate was neutralised with hydrochloric acid, evaporated to dryness, basified with excess of 50% aqueous potassium hydroxide, and extracted with ether. The dried extract was fractionated, giving 2-amino-3-methoxybutane (5 g.) as colourless oil, b. p. 114–116° (Found : N, 13.3. $C_6H_{13}ON$ requires N, 13.6%). The *platinichloride* formed orange prisms from methyl alcohol–ether, m. p. 189–190° (decomp.) (Found : Pt, 31.1. $(C_6H_{13}ON)_3, H_4PtCl_6$ requires Pt, 31.6%); the 2 : 4-dinitrophenylurea (cf. McVeigh and Rose, *J.*, 1945, 621) formed yellow prisms from alcohol, m. p. 152–154° (Found : C, 45.9; H, 4.7; N, 17.6. $C_{12}H_{15}O_6N_4$ requires C, 46.1; H, 5.1; N, 17.9%). The same amine was formed in 50% yield by catalytic reduction of the nitro-ether with Raney nickel–methyl alcohol at 50°/120 atms.

2-Nitrobut-2-ene.—2-Nitro-3-acetoxybutane (161 g.; Vanderbilt and Hass, *loc. cit.*) was stirred with anhydrous sodium acetate (0.6 g.) at 100° for 1 hour and then distilled. The acidic distillate was washed successively with brine, aqueous sodium hydrogen carbonate, and brine, and the product fractionated, giving 2-nitrobut-2-ene (86 g.) as a pale yellow liquid, b. p. 55.5°/15 mm., n_D^{20} 1.4600 (Found : C, 46.9; H, 6.8; N, 13.8. $C_4H_7O_2N$ requires C, 47.5; H, 6.9; N, 13.8%). Reduction of the nitro-olefin (30 g.) with zinc and acetic acid (cf. Bouveault and Wahl, *loc. cit.*) gave methyl ethyl ketoxime (17 g.), b. p. 140–150°, which with 2 : 4-dinitrophenylhydrazine in hydrochloric acid gave methyl ethyl ketone 2 : 4-dinitrophenylhydrazone, m. p. and mixed m. p. with an authentic specimen, 115°.

The authors wish to thank Mr. R. H. Stanley and Mr. H. Baldock for assistance with the preparative work, and Dr. N. Levy and Dr. H. A. Piggott for their interest and advice.

283. Aliphatic Nitro-compounds. Part IV. Addition of Thiols to α -Nitro-olefins.*

By R. L. HEATH and A. LAMBERT.

Thiols and hydrogen sulphide react with α -nitro-olefins under basic conditions, giving 2-nitroalkyl sulphides or thiols. The former can be oxidised to 2-nitroalkyl sulphones (also formed from the nitro-olefin and, e.g., sodium *p*-toluenesulphonate) or reduced to 2-aminoalkyl sulphides, which on oxidation give 2-aminoalkyl sulphones. In certain cases the 2-nitro-alcohols or their esters can be used as convenient substitutes for the nitro-olefins.

* Patent application pending.

As a logical extension of the synthesis of alkyl 2-nitroalkyl ethers by interaction of an α -nitro-olefin with an alcohol (see Part III of this series), the addition of thiols and hydrogen sulphide to nitro-olefins was investigated. This addition was found to be of wide application, and was more facile than the corresponding addition of alcohols.

In the presence of sodium methoxide, 2-nitroprop-1-ene and methylthiol gave an 86% yield of *methyl 2-nitropropyl sulphide*; similarly *methyl 2-nitro-1-methylpropyl sulphide* was obtained from 2-nitrobut-2-ene and methylthiol, *2-nitropropyl butyl sulphide* from 2-nitroprop-1-ene and butylthiol, *methyl 2-nitro-1-phenylethyl sulphide* from β -nitrostyrene and methylthiol, and *phenyl 2-nitroisopropyl sulphide* from 1-nitroprop-1-ene and thiophenol.

That thiols add to nitro-olefins with greater facility than do alcohols is well illustrated by the interaction of *n*-butylthiol with 2-nitroprop-1-ene; in the absence of a catalyst, this yielded 20% of 2-nitropropyl *n*-butyl sulphide, whilst only traces of methyl 2-nitropropyl ether are formed by refluxing methyl alcohol and the nitro-olefin; further, interaction of equimolecular proportions of sodium methoxide and 2-nitroprop-1-ene gave, in addition to the expected methyl 2-nitropropyl ether, some methyl 2 : 4-dinitro-2-methylamyl ether, formed by addition of the nitro-ether to unchanged nitro-olefin (cf. Part III of this series), but in the corresponding reaction with sodium thiomethoxide in place of sodium methoxide, this type of side reaction does not occur.

In the presence of piperidine as catalyst, nitro-*tert.*-butyl alcohol behaved as 1-nitro-2-methylprop-1-ene, and with butylthiol afforded *butyl nitro-tert.-butyl sulphide*; as in many examples cited in other parts of this series, 2-nitroethyl nitrate could be used as a convenient source of nitroethylene, and reacted with sodium thioalkoxides to give alkyl (or aryl) 2-nitroethyl sulphides. *Methyl, p-tolyl, p-n-butylphenyl, and carboxymethyl 2-nitroethyl sulphides* were prepared by this method, and sodium thiolacetate gave *2-nitroethyl thiolacetate*.

The addition of water to nitro-olefins in the presence of a basic catalyst is known to yield, in certain cases, 2-nitro-alcohols. It has been found that hydrogen sulphide reacts with nitro-olefins more readily than does water, and in the absence of catalysts, 2-nitrothiols are formed many of which react further with the nitro-olefin, giving di-(2-nitroalkyl) sulphides. The yields of thiol and sulphide vary widely from case to case, and are tabulated below.

Nitro-olefin.	Products and yield.
Nitroethylene	2-Nitroethylthiol (18%) and di-(2-nitroethyl) sulphide (48%)
2-Nitroprop-1-ene	2-Nitropropylthiol (7%)
1-Nitro-2-methylprop-1-ene	Nitro- <i>tert.</i> -butylthiol (31%) and di(nitro- <i>tert.</i> -butyl) sulphide (trace)
2-Nitrobut-2-ene	Di-(2-nitro-1-methylpropyl) sulphide (25%)
β -Nitrostyrene	Di-(2-nitro-1-phenylethyl) sulphide (37%)

The low yield of 2-nitropropylthiol obtained from 2-nitroprop-1-ene was due to the formation of much unstable high-boiling material. In the condensation of 2-nitrobut-2-ene with hydrogen sulphide, some thiol was formed but could not be obtained pure by distillation. The product from β -nitrostyrene was a mixture from which only one stereoisomeride of *di-(2-nitro-1-phenylethyl) sulphide* could be isolated.

In addition to their formation from nitroethylene and hydrogen sulphide, *2-nitroethylthiol* and *di-(2-nitroethyl) sulphide* were also obtained from 2-nitroethyl nitrate with potassium hydrogen sulphide and potassium sulphide respectively, and hydrolysis of 2-nitroethyl thiolacetate (from thiolacetic acid and 2-nitroethyl nitrate) also gave 2-nitroethylthiol in small yield. 1-Nitro-2-methylprop-1-ene and sodium sulphide gave *di(nitro-tert.-butyl) sulphide* and nitro-*tert.*-butylthiol.

Oxidation of nitroalkyl sulphides with hydrogen peroxide in acetic acid afforded the nitroalkyl sulphones in good yield. Thus, *p*-tolyl 2-nitroethyl sulphide gave *p-tolyl 2-nitroethyl sulphone*, which is also obtained by reaction of sodium *p*-toluenesulphinate with 2-nitroethyl nitrate or nitroethylene. Catalytic reduction (Raney nickel) of the nitro-sulphones yielded amino-sulphones, and these were also formed by similar reduction of the nitroalkyl sulphides to aminoalkyl sulphides, followed by oxidation with hydrogen peroxide.

EXPERIMENTAL.

Analyses are by Mr. E. S. Morton. All m. ps. are uncorrected.

Methyl 2-Nitro-1-methylpropyl Sulphide.—A solution of sodium methoxide (from sodium (9.6 g.) in methyl alcohol (100 c.c.)) was added slowly with stirring to a solution of methylthiol (24 g.) in methyl alcohol (60 c.c.) at -5° . 2-Nitrobut-2-ene (42 g.; see Part III of this series) was then added dropwise during 40 minutes with stirring at $0-5^{\circ}$, and, after being stirred for a further hour, the solution was poured into ice-water (400 c.c.), acidified with dilute acetic acid, and extracted with ether. Fractionation

of the dried extract gave *methyl 2-nitro-1-methylpropyl sulphide* (26 g.) as a colourless unpleasant smelling oil, b. p. 91—96°/15 mm. (Found : N, 9.1. $C_5H_{11}O_2NS$ requires N, 9.4%).

Methyl 2-Nitropropyl Sulphide.—2-Nitroprop-1-ene (30 g.; Part I of this series) was brought into reaction with methylthiol (20 g.) as described above. *Methyl 2-nitropropyl sulphide* (40 g.) was obtained as a colourless liquid, b. p. 98—100°/16 mm. (Found : N, 10.2. $C_4H_9O_2NS$ requires N, 10.4%).

Methyl 2-Nitropropyl Sulphone.—Hydrogen peroxide (30%; 45 c.c.) was added quickly with shaking to a boiling solution of methyl 2-nitropropyl sulphide (10 g.) in glacial acetic acid (40 c.c.). The mixture was boiled for 1 hour and evaporated to dryness under reduced pressure at 40—50°. Crystallisation of the residue from benzene gave *methyl 2-nitropropyl sulphone*, m. p. 69—70° (Found : C, 28.8; H, 5.1; N, 7.9. $C_4H_9O_4NS$ requires C, 28.7; H, 5.4; N, 8.4%).

Methyl 2-Aminopropyl Sulphone.—Methyl 2-nitropropyl sulphone (12 g.) in methyl alcohol (600 c.c.) was shaken with Raney nickel and hydrogen (75 atms. initial pressure) at room temperature. Distillation of the product gave methyl 2-aminopropyl sulphone (2 g.) as a viscous pale yellow oil, b. p. 110—120°/0.3 mm.; the residue decomposed. The benzoyl derivative formed colourless needles from ethyl acetate, m. p. 154° (Found : N, 5.9; S, 13.9. $C_{11}H_{15}O_3NS$ requires N, 5.8; S, 13.3%).

Phenyl 2-Nitroisopropyl Sulphide.—Thiophenol (10 g.) was added to a solution of sodium (2.1 g.) in methyl alcohol (50 c.c.) at 0°. 1-Nitroprop-1-ene (7.9 g.; Part I of this series) was added dropwise with stirring at 0—5° and the product treated as described above for the preparation of methyl 2-nitro-1-methylpropyl sulphide. *Phenyl 2-nitroisopropyl sulphide* (11.5 g.) was obtained as a colourless liquid, b. p. 110—111°/0.1 mm. (Found : N, 6.9. $C_9H_{11}O_2NS$ requires N, 7.1%).

Methyl 2-Nitro-1-phenylethyl Sulphide.—A solution of sodium methoxide [from sodium (9.2 g.) in methyl alcohol (100 c.c.)] was added slowly with stirring to a solution of methylthiol (21 g.) in methyl alcohol at —10°. A solution of β -nitrostyrene (29.8 g.) in dioxan (500 c.c.) was then added dropwise with stirring during $\frac{1}{2}$ hour at 10°. After being stirred at room temperature for $\frac{1}{2}$ hour, the mixture was poured into water and extracted with ether. Distillation of the dried ethereal extract gave *methyl 2-nitro-1-phenylethyl sulphide* (19.1 g.) as a yellow oil, b. p. 168—172°/22 mm. (Found : N, 6.7. $C_9H_{11}O_2NS$ requires N, 6.9%).

2-Nitropropyl Butyl Sulphide.—Butylthiol (10.4 g.) was added to a solution of sodium (2.7 g.) in methyl alcohol (50 c.c.) at 0°. 2-Nitroprop-1-ene (10 g.) was then added dropwise with stirring at 0—10° and the product isolated in the usual way. *2-Nitropropyl butyl sulphide* (12 g.) was obtained as a colourless liquid, b. p. 124—128°/13 mm. (Found : N, 7.8. $C_7H_{15}O_2NS$ requires N, 7.9%). The same product was also obtained by interaction of *n*-butylthiol and 2-nitroprop-1-ene in absence of a catalyst. Equimols. of the reactants were warmed in methyl alcohol solution until reaction commenced, heating was discontinued, and the mixture kept for 12 hours, diluted with ether, washed with sodium hydrogen carbonate and with water, and finally distilled, giving 2-nitropropyl butyl sulphide, b. p. 120—130°/16 mm. in 19% yield. Identity was established by oxidation to the sulphone (see below).

2-Nitropropyl Butyl Sulphone.—Prepared from the sulphide by oxidation with hydrogen peroxide in glacial acetic acid, the sulphone separated from methyl alcohol in colourless plates, m. p. 36—37° (Found : N, 6.2; S, 14.7. $C_8H_{15}O_4NS$ requires N, 6.7; S, 15.3%).

n-Butyl Nitro-tert.-butyl Sulphide.—A mixture of *n*-butylthiol (7.0 g.), nitro-*tert.*-butyl alcohol (10 g.; see Part XVIII of this series), and piperidine (1 g.) was kept at 20° for 3 days. The mixture was neutralised with 2*N*-hydrochloric acid, diluted with ether, and washed with water. Distillation of the ethereal solution gave *n-butyl nitro-tert.-butyl sulphide* (8.6 g.) as a colourless liquid, b. p. 124°/11 mm. (Found : C, 50.4; H, 8.6; N, 7.2. $C_8H_{17}O_2NS$ requires C, 50.3; H, 8.9; N, 7.3%).

m-Di(nitro-tert.-butylsulphonyl)benzene.—Dithioresorcinol (14.2 g.) was added with stirring to a solution of sodium methoxide [from sodium (4.6 g.) in methyl alcohol (160 c.c.)] at 0—10°. 1-Nitro-2-methylprop-1-ene (20.2 g.; Levy and Scaife, in the press) was added dropwise at 0—5°, and the mixture stirred at room temperature for a further 2 hours. The product was poured into ice-water, acidified with dilute acetic acid, and extracted with ether. Distillation of the ethereal extract gave a colourless oil (18.1 g.), b. p. 130°/0.5 mm. The sulphur content of this oil (Found : S, 24.7. Calc. for $C_{14}H_{20}O_4N_2S_2$: S, 18.6%) indicated that it was contaminated with dithioresorcinol. However, on oxidation with hydrogen peroxide in glacial acetic acid pure *m-di(nitro-tert.-butylsulphonyl)benzene* was obtained in 17% yield. It separated from methyl alcohol in colourless needles, m. p. 166—168° (Found : N, 7.1. $C_{14}H_{20}O_4N_2S_2$ requires N, 6.9%).

Methyl 2-Nitroethyl Sulphide.—A solution of methylthiol (9.6 g.) in methyl alcohol (50 c.c.) was added to a solution of sodium methoxide (10.8 g.) in methyl alcohol (30 c.c.) at —10°. 2-Nitroethyl nitrate (27.2 g.; Levy, Scaife, and Wilder-Smith, *J.*, 1946, 1096) was added dropwise with stirring at —5°, and, after being stirred for 3½ hours at 0°, the solution was filtered and distilled, giving *methyl 2-nitroethyl sulphide*, b. p. 105°/20 mm., in 80% yield (Found : C, 30.2; H, 5.8; N, 11.1. $C_3H_7O_2NS$ requires C, 29.8; H, 5.8; N, 11.6%).

Methyl 2-Aminoethyl Sulphide.—Methyl 2-nitroethyl sulphide (40 g.) in methyl alcohol (700 c.c.) was hydrogenated over Raney nickel at 50—60° and 100 atms. (initial pressure). Fractionation of the product gave methyl 2-aminoethyl sulphide (20 g.) as a colourless liquid, b. p. 90—91°/114 mm. (Schneider, *Annalen*, 1912, 386, 337, gives b. p. 146—148°/760 mm.). The picrate had m. p. 119° (Schneider, *loc. cit.*, gives m. p. 119°).

Methyl 2-Nitroethyl Sulphone.—Oxidation of methyl 2-nitroethyl sulphide (12.1 g.) with hydrogen peroxide in boiling glacial acetic acid gave *methyl 2-nitroethyl sulphone* (12.1 g.), colourless needles from alcohol, m. p. 78° (Found : C, 23.3; H, 5.1; N, 9.1. $C_3H_7O_4NS$ requires C, 23.5; H, 4.6; N, 9.1%).

Methyl 2-Aminoethyl Sulphone.—Methyl 2-nitroethyl sulphone (3.06 g.) in methyl alcohol (40 c.c.) was hydrogenated (Raney nickel) at ordinary temperature and pressure. Distillation of the product gave *methyl 2-aminoethyl sulphone* as a colourless liquid, b. p. 180°/0.02 mm., in almost quantitative yield (Found : N, 10.9. $C_3H_7O_4NS$ requires N, 11.4%). The hydrochloride had m. p. 168° (Schneider, *loc. cit.*, gives m. p. 169°), and the benzoyl derivative, m. p. 134° (Schneider, *loc. cit.*, gives m. p. 134°).

p-n-Butylphenyl 2-Nitroethyl Sulphone.—2-Nitroethyl nitrate (16.4 g.) was added dropwise to a stirred solution of sodium thio-*p*-butylphenol (22.6 g.) in methyl alcohol (200 c.c.) at —10° to —5°.

After being stirred for 4 hours the mixture was filtered, evaporated to dryness, and extracted with ether. Removal of the ether gave crude *p*-*n*-butylphenyl 2-nitroethyl sulphide as a colourless syrup which on oxidation with hydrogen peroxide gave *p*-*n*-butylphenyl 2-nitroethyl sulphone as colourless needles from alcohol, m. p. 91–92° (Found: C, 53.1; H, 6.4; N, 5.3. $C_{15}H_{17}O_4NS$ requires C, 53.1; H, 6.3; N, 5.2%).

Carboxymethyl 2-Nitroethyl Sulphide.—To a solution of thioglycolic acid (9.2 g.) and sodium methoxide (10.8 g.) in methyl alcohol (150 c.c.), 2-nitroethyl nitrate (13.6 g.) was added dropwise with stirring at 0–5°. After being stirred for 3 hours at 0–20° the mixture was filtered, treated with 2*N*-hydrochloric acid (50 c.c.), evaporated to dryness, and extracted with ether. Removal of the ether gave *carboxymethyl 2-nitroethyl sulphide* (9.9 g.) as a colourless syrup which solidified on standing, and crystallised from toluene, m. p. 47° (Found: C, 29.4; H, 4.0; N, 8.5. $C_4H_7O_4NS$ requires C, 29.1; H, 4.2; N, 8.5%).

Carboxymethyl 2-Nitroethyl Sulphone.—Oxidation of *carboxymethyl 2-nitroethyl sulphide* with hydrogen peroxide in boiling glacial acetic acid gave *carboxymethyl 2-nitroethyl sulphone* in almost quantitative yield. From alcohol-ether-light petroleum (b. p. 40–60°), white crystals, m. p. 115–116°, were obtained (Found: C, 24.7; H, 3.9; N, 7.1. $C_4H_7O_6NS$ requires C, 24.4; H, 3.6; N, 7.1%). The *ethyl ester*, prepared in almost quantitative yield by heating the acid in alcoholic solution, formed colourless crystals from alcohol, m. p. 62° (Found: C, 32.2; H, 4.8; N, 6.3. $C_6H_{11}O_6NS$ requires C, 32.0; H, 4.8; N, 6.2%).

Carboxymethyl 2-Aminoethyl Sulphide.—*Carboxymethyl 2-nitroethyl sulphide* (8.0 g.) in methyl alcohol (200 c.c.) was hydrogenated over Raney nickel at ordinary temperature and pressure. After filtration, removal of the methyl alcohol gave a nickel salt, which was dissolved in water and decomposed by hydrogen sulphide. The solution was filtered from nickel sulphide and evaporated to dryness. Crystallisation of the residue from alcohol gave *carboxymethyl 2-aminoethyl sulphide* (2.8 g.), m. p. 156° (Found: C, 35.3; H, 5.5; N, 10.6. $C_4H_9O_2NS$ requires C, 35.5; H, 6.6; N, 10.3%).

2-Nitroethyl Thiocacetate.—To a solution of thiocetic acid (15.2 g.) and sodium methoxide (10.8 g.) in methyl alcohol (200 c.c.), 2-nitroethyl nitrate (27.2 g.) was added dropwise with stirring at 0–5°. After being stirred for 2 hours, the filtered solution was evaporated and distilled, giving *2-nitroethyl thiocacetate* (23.1 g.), b. p. 68–70°/0.1 mm. (Found: C, 32.0; H, 5.4; N, 9.4. $C_4H_7O_3NS$ requires C, 32.2; H, 4.7; N, 9.4%).

2-Nitroethylthiol.—(a) *From nitroethylene and hydrogen sulphide.* Nitroethylene (20 g.; Part I of this series) was added slowly with stirring to a saturated solution of hydrogen sulphide in alcohol (350 c.c.) at 0°. The vessel was then sealed and kept at 20° for 2 hours; some di-(2-nitroethyl) sulphide separated at this stage. After removal of the alcohol, distillation of the residue in nitrogen gave *2-nitroethylthiol* (5.2 g.) as a colourless liquid, b. p. 86–87°/14 mm. (Found: C, 22.4; H, 4.3; N, 12.9; S, 29.5. $C_4H_7O_2NS$ requires C, 22.4; H, 4.7; N, 13.1; S, 29.9%), and *di-(2-nitroethyl) sulphide* (11.8 g.) as a pale yellow oil, b. p. 140–144°/0.2 mm., which darkened on standing (Found: S, 17.8. $C_6H_9O_4N_2S$ requires S, 17.8%).

(b) *From 2-nitroethyl nitrate and potassium hydrogen sulphide.* 2-Nitroethyl nitrate (13.6 g.) was added dropwise with stirring to a solution of potassium hydrogen sulphide (7.2 g.) in methyl alcohol (100 c.c.) at room temperature. After being stirred for 3 hours, the mixture was filtered, evaporated to dryness, and extracted with ether. Distillation of the ethereal solution gave *2-nitroethylthiol* (2.1 g.), b. p. 95°/20 mm.

(c) *By hydrolysis of 2-nitroethyl thiocacetate.* 2-Nitroethyl thiocacetate (7.4 g.) was kept for 1 hour at 20° with a solution of sodium hydroxide (4 g.) in water (70 c.c.). The solution was acidified with dilute hydrochloric acid and extracted with ether. The ethereal solution, washed free of acetic acid with aqueous sodium hydrogen carbonate, was distilled in nitrogen, giving *2-nitroethylthiol* (0.5 g.), b. p. 95–100°/20 mm. Mercury 2-nitrothioethoxide, prepared from the thiol and mercuric cyanide in alcohol, separated from alcohol in colourless needles, m. p. 67–68°. It decomposed rapidly on standing. *2:4-Dinitrophenyl 2-nitroethyl sulphide* was prepared by addition of 1-chloro-2:4-dinitrobenzene (1.1 g.) in alcohol (20 c.c.) to a solution of the thiol (0.6 g.) in *N*-sodium hydroxide (5.5 c.c.). The solution was heated to boiling and the product which separated crystallised from benzene, m. p. 196–197° (Found: N, 15.6. $C_8H_9O_6N_3S$ requires N, 15.4%).

Di-(2-nitroethyl) Sulphide.—2-Nitroethyl nitrate (27.2 g.) was added dropwise to a stirred solution of potassium sulphide (11.0 g.) in methyl alcohol (200 c.c.) at 0–5°. After being stirred for 2 hours, the filtered solution was evaporated to dryness, the residue extracted with acetone, and the extract distilled, yielding *di-(2-nitroethyl) sulphide* (9 g.) identical with that obtained from nitroethylene and hydrogen sulphide. Oxidation of the samples with hydrogen peroxide gave identical specimens of *di-(2-nitroethyl) sulphone*, colourless plates from acetone, m. p. 132° (Found: C, 22.6; H, 3.7; N, 13.2. $C_6H_9O_4N_2S$ requires C, 22.6; H, 3.8; N, 13.2%).

Nitro-tert.-butylthiol and Di(nitro-tert.-butyl) Sulphide.—(a) *From sodium sulphide.* 1-Nitro-2-methylprop-1-ene (101 g.) was added slowly to a stirred solution of sodium sulphide ($Na_2S \cdot 9H_2O$; 120 g.) in water (450 c.c.) at 0–10°. When homogeneous, the solution was treated with acetic acid (120 c.c. of 50%) and extracted with ether. Distillation afforded a fraction, b. p. 46–64°/7 mm. (38 g.), from which unchanged nitro-olefin was extracted with aqueous sodium hydrogen sulphite, giving *nitro-tert.-butylthiol* (12 g.), b. p. 58–63°/7 mm. (Found: C, 35.9; H, 6.3; N, 11.0; S, 22.9. $C_4H_9O_2NS$ requires C, 35.6; H, 6.7; N, 10.4; S, 23.7%). Mercury nitro-tert.-thiobutoxide, colourless needles from alcohol, m. p. 108°, decomposes slowly on keeping. The residue, after removal of the fraction, b. p. 46–64°/7 mm., was crystallised from benzene-light petroleum to give *di(nitro-tert.-butyl) sulphide*, m. p. 59–60° (Found: C, 40.8; H, 6.8; S, 13.5. $C_8H_{15}O_4N_2S$ requires C, 40.7; H, 6.8; S, 13.6%).

(b) *From hydrogen sulphide.* A solution of 1-nitro-2-methylprop-1-ene (20 g.) in alcohol (350 c.c.) was saturated at 0° with hydrogen sulphide and kept in a sealed vessel for 7 days at 20°. The alcohol was distilled and the residue, after extraction with aqueous sodium hydrogen sulphite, was isolated with ether and distilled giving *nitro-tert.-butylthiol* (8.4 g.), b. p. 68°/8 mm., and a residue (0.5 g.) which, after crystallisation from benzene-light petroleum, afforded *di(nitro-tert.-butyl) sulphide*, m. p. 59–60°.

Di(nitro-tert.-butyl) Sulphone.—Oxidation of di(nitro-tert.-butyl) sulphide with hydrogen peroxide in the manner described above gave di(nitro-tert.-butyl) sulphone, long colourless needles from methyl alcohol, m. p. 186° (Found: N, 10.4. $C_8H_{16}O_6N_2S$ requires N, 10.4%).

Di-(2-nitro-1-methylpropyl) Sulphide.—A solution of 2-nitrobut-2-ene (27.4 g.) in alcohol (350 c.c.) was saturated with hydrogen sulphide at 0°. The vessel was then sealed and kept at room temperature for 16 hours. After filtration and removal of the alcohol, distillation of the residue in a stream of nitrogen gave an almost colourless liquid, b. p. 70–90°/15 mm., and di-(2-nitro-1-methylpropyl) sulphide (3 g.), b. p. 110°/0.04 mm. (Found: S, 13.4. $C_8H_{16}O_4N_2S$ requires S, 13.6%). The fraction, b. p. 70–90°/15 mm., appeared to be a mixture of unchanged nitro-olefin and the stereoisomerides of 2-nitro-1-methylpropylthiol, but attempts to separate them by distillation failed. Redistillation of this material after 2 weeks, however, gave more (5 g.) di-(2-nitro-1-methylpropyl) sulphide, indicating reaction between the components.

Di-(2-nitro-1-methylpropyl) Sulphone.—Oxidation of the crude sulphide with hydrogen peroxide in the usual way gave a mixture of stereoisomerides of di-(2-nitro-1-methylpropyl) sulphone which separated from benzene–light petroleum (b. p. 60–80°) in colourless needles, m. p. 92–98° (Found: C, 35.8; H, 6.0; N, 10.2. $C_8H_{16}O_6N_2S$ requires C, 35.8; H, 6.0; N, 10.4%).

2-Nitropropylthiol.—2-Nitroprop-1-ene (20 g.) was added slowly with stirring to a saturated solution of hydrogen sulphide in alcohol (350 c.c.) at 0°. The vessel was then sealed and kept at 20° for 1½ hours. After removal of the alcohol, distillation of the residue gave 2-nitropropylthiol (2 g.) as a colourless liquid, b. p. 83°/12 mm. (Found: S, 25.8. $C_3H_7O_2NS$ requires S, 26.4%). The dark residue decomposed on attempted distillation at 0.2 mm.

Di-(2-nitro-1-phenylethyl) Sulphide.—A solution of β -nitrostyrene (30 g.) in alcohol (350 c.c.) was saturated with hydrogen sulphide at 0°. The vessel was then sealed and kept at 20° for 2 hours. On cooling to 0°, di-(2-nitro-1-phenylethyl) sulphide (9.5 g.) separated as a colourless solid which crystallised from alcohol in large prisms, m. p. 106–107° (Found: N, 8.3; S, 9.5. $C_{16}H_{16}O_4N_2S$ requires N, 8.4; S, 9.6%). The bulk of the product remained in the mother liquors as a viscous oil, b. p. 80–120°/0.08 mm.; this mixture of stereoisomerides was not separated.

p-Tolyl 2-Nitroethyl Sulphone.—(a) *From nitroethylene*. Nitroethylene (3.7 g.) was added slowly to a stirred solution of sodium *p*-toluenesulphinate (8.9 g.) in water (25 c.c.) at 0°. After being stirred at 0° for 3 hours, the mixture was filtered from polynitroethylene, acidified with acetic acid, and extracted with ether. Concentration of the ethereal solution gave *p*-tolyl 2-nitroethyl sulphone (0.6 g.) as colourless needles, m. p. 114° (from alcohol) (Found: C, 46.8; H, 5.0; N, 6.6. $C_9H_{11}O_4NS$ requires C, 47.2; H, 4.8; N, 6.1%).

(b) *From 2-nitroethyl nitrate and sodium p-toluenesulphinate*. 2-Nitroethyl nitrate (13.6 g.) was added dropwise to a stirred solution of sodium *p*-toluenesulphinate (17.8 g.) in water (50 c.c.) at 20°. The product was filtered off and crystallised from alcohol, giving *p*-tolyl 2-nitroethyl sulphone (18.3 g.), m. p. and mixed m. p. 114°.

(c) *From p-tolyl 2-nitroethyl sulphide*. A solution of sodium methoxide [from sodium (2.3 g.) in methyl alcohol (50 c.c.)] was added to a solution of thio-*p*-cresol (12.4 g.) in methyl alcohol (100 c.c.) at 0°. 2-Nitroethyl nitrate (13.6 g.) was then added dropwise with stirring at –10° to –5°. After being stirred for 3 hours the filtered solution was evaporated, giving crude *p*-tolyl 2-nitroethyl sulphide as a colourless oil, which on oxidation with hydrogen peroxide in acetic acid gave *p*-tolyl 2-nitroethyl sulphone (21 g.), m. p. and mixed m. p. 114°.

p-Tolyl 2-Aminoethyl Sulphone.—*p*-Tolyl 2-nitroethyl sulphone (2.3 g.) in methyl alcohol (40 c.c.) was hydrogenated over Raney nickel at ordinary temperature and pressure. Evaporation of the filtered solution gave *p*-tolyl 2-aminoethyl sulphone as a colourless syrup. The benzoyl derivative had m. p. 158° (Found: C, 63.2; H, 5.7; N, 4.7. $C_{16}H_{17}O_2NS$ requires C, 63.3; H, 5.6; N, 4.6%).

p-Tolyl 2-Aminoethyl Sulphide.—Crude *p*-tolyl 2-nitroethyl sulphide (5 g.) in methyl alcohol (50 c.c.) was hydrogenated over Raney nickel at ordinary temperature and pressure. Removal of the methyl alcohol gave a colourless syrup, which with ethereal hydrogen chloride yielded *p*-tolyl 2-aminoethyl sulphide hydrochloride (4.1 g.), colourless crystals from alcohol-ether, m. p. 132° (Found: C, 53.3; H, 6.9; N, 6.8. $C_9H_{13}NS.HCl$ requires C, 53.1; H, 6.9; N, 6.9%).

The authors wish to acknowledge the interest and advice of Dr. H. A. Piggott and Mr. J. D. Rose in this work.

284. Aliphatic Nitro-compounds. Part V. Preparation of 2-Nitroalkanesulphonic Acids by Interaction of α -Nitro-olefins and Sodium Hydrogen Sulphite.*

By R. L. HEATH and H. A. PIGGOTT.

α -Nitro-olefins react with sodium hydrogen sulphite giving sodium 2-nitroalkanesulphonates, which on catalytic reduction afford the corresponding 2-aminoalkanesulphonic acids in good yield. In the absence of oxygen, sulphurous acid can be used in place of sodium hydrogen sulphite, and in many cases esters of 2-nitro-alcohols (2-nitroethyl nitrate, 2-nitropropyl acetate) behave in the same way as the nitro-olefins.

* Cf. E.P. 571,157.

THE interaction of α -nitro-olefins and sodium hydrogen sulphite was studied during a general investigation of the addition reactions of nitro-olefins, as a potentially interesting route to certain 2-aminoalkanesulphonic acids required as intermediates in the synthesis of dyestuffs.

The addition of alkali hydrogen sulphites to unsaturated substances has been studied by many workers. Rosenthal (*Annalen*, 1886, 233, 38) prepared the diammonium salt of β -sulphopropionic acid by the interaction of ammonium hydrogen sulphite and ammonium acrylate. The addition of potassium hydrogen sulphite to allyl alcohol was demonstrated by Müller (*Ber.*, 1873, 6, 1442), and the product was established by Marckwald (*ibid.*, 1898, 31, 1864) as potassium 1-hydroxypropane-3-sulphonate. Kolker and Lapworth (*J.*, 1925, 307) added ammonium hydrogen sulphite to a large number of olefins, whilst the reaction of sodium hydrogen sulphite and styrene, first reported by Ashworth and Burkhardt (*J.*, 1928, 1791), has been shown by Kharasch, Schenck, and Mayo (*J. Amer. Chem. Soc.*, 1939, 61, 3092) to yield 2-phenylethane-1-sulphonic acid, 2-phenylethylene-1-sulphonic acid, 2-phenylethane-1:1-disulphonic acid, and 2-hydroxy-2-phenylethane-1-sulphonic acid. Knoevenagel and Morrisse (*Ber.*, 1904, 37, 4038) successfully added alkali hydrogen sulphites to $\alpha\beta$ -unsaturated aldehydes and ketones, and the addition to unsaturated furyl compounds has been described by the American Cyanamide Co. (*Brit. Appl.* 14357/43).

The formation of alkali 2-nitroalkanesulphonates by interaction of an α -nitro-olefin and alkali hydrogen sulphite was found to be a general reaction; in the absence of oxygen, sulphurous acid behaved in a similar way, giving the free nitro-sulphonic acid, but in the presence of oxygen sulphamic acid was formed, probably by (a) oxidation of sulphurous to sulphuric acid, (b) formation of hydroxylamine from sulphuric acid and the nitro-olefin, and (c) interaction of hydroxylamine and sulphur dioxide. The use of sodium sulphite in this reaction resulted in the formation of the sodium salt of the sodium *aci*-nitroalkanesulphonate, and in two cases esters of 2-nitro-alcohols have been shown to react in the same way as the nitro-olefins.

Accurate analyses of the nitroalkanesulphonates were not easy to obtain owing to the difficulty of freeing them from the last traces of moisture, and many were characterised as their *p*-toluidine salts (see Chambers and Watt, *J. Org. Chem.*, 1941, 6, 376). All attempts to characterise them by salts of *S*-benzylisothiurea were unsuccessful.

The *sulphonates* which have been prepared are listed in the Table.

Nitro-compound.	Sulphite.	Nitro-sulphonate.
Nitroethylene	NaHSO ₃	Na 2-nitroethanesulphonate
2-Nitroethyl nitrate	NaHSO ₃	Na 2-nitroethanesulphonate
1-Nitroprop-1-ene	NaHSO ₃	Na 1-nitropropane-2-sulphonate
1-Nitroprop-1-ene	H ₂ SO ₃	1-Nitropropane-2-sulphonic acid
1-Nitroprop-1-ene	Na ₂ SO ₃	Na ₂ 1- <i>aci</i> -nitropropane-2-sulphonate
2-Nitroprop-1-ene	NaHSO ₃	Na 2-nitropropane-1-sulphonate
2-Nitropropyl acetate	NaHSO ₃	Na 2-nitropropane-1-sulphonate
1-Nitro-2-methylprop-1-ene	NaHSO ₃	Na 1-nitro-2-methylpropane-2-sulphonate
1-Nitro-2-methylprop-1-ene	H ₂ SO ₃	1-Nitro-2-methylpropane-2-sulphonic acid
2-Nitrobut-2-ene	NaHSO ₃	Na 2-nitrobutane-3-sulphonate and (?) Na 2-oximinobutane-3-sulphonate
2-Nitrostyrene	NaHSO ₃	Na 1-nitro-2-phenylethane-2-sulphonate
2-Nitrostyrene	H ₂ SO ₃	1-Nitro-2-phenylethane-2-sulphonic acid
1-Nitro-2-(2-furyl)ethylene	NaHSO ₃	Na 1-nitro-2-(2-furyl)ethane-2-sulphonate
Ethyl α -nitro- $\beta\beta$ -dimethylacrylate	NaHSO ₃	Na 1-nitro-1-carbethoxy-2-methylpropane-2-sulphonate

A few deviations from the normal reaction course were noted. 1-Nitrocyclohexane and 2-nitro-1-phenylprop-1-ene with sodium hydrogen sulphite gave viscous syrups which could not be characterised and on reduction gave nitrogen-free products. 2-Nitrobut-2-ene, condensed with sodium hydrogen sulphite in an atmosphere of nitrogen, gave a syrupy and a crystalline condensation product both of which on reduction yielded amino-sulphonic acids which, whilst agreeing in analysis with the expected 2-aminobutanesulphonic acid, were not identical. The original crystalline product may be the oximinobutanesulphonic acid, but the structures of the amino-sulphonic acids have not been determined.

The interaction of ethyl α -nitro- $\beta\beta$ -dimethylacrylate and sodium hydrogen sulphite was described by Bouveault and Wahl (*Bull. Soc. chim.*, 1901, 25, 910) who made no attempt to isolate or characterise the reaction product. This has been repeated and the product shown to be that of normal addition.

Reduction of the nitro-sulphonates with Raney nickel and hydrogen gave good yields of the corresponding amino-sulphonic acids; in most cases the reduction was sufficiently facile to

proceed at ordinary temperature and pressure and in only a few was it necessary to use hydrogen under pressure.

EXPERIMENTAL.

Analyses are by Mr. E. S. Morton. All m. ps. are uncorrected.

Sodium 2-Nitroethanesulphonate.—(a) *From nitroethylene.* Nitroethylene (27.5 g.; this series, Part I) was added dropwise to a vigorously stirred solution of sodium hydrogen sulphite (39.2 g.) in water (70 c.c.) at -5° to 0° and stirring continued at this temperature for 2 hours and finally at 20° for 4 hours. The mixture was evaporated under reduced pressure at 40° and the residue extracted with absolute alcohol, giving sodium 2-nitroethanesulphonate in 75% yield. The salt was recrystallised from alcohol (Found: N, 7.9. $\text{C}_2\text{H}_4\text{O}_2\text{NSNa}$ requires N, 7.9%). The *p*-toluidine salt, prepared by addition of aqueous *p*-toluidine hydrochloride to the aqueous sodium salt, formed needles from absolute alcohol, m. p. 179° (decomp.) (Found: C, 40.6; H, 5.5; N, 10.6. $\text{C}_9\text{H}_{10}\text{O}_2\text{NS}_2\text{C}_6\text{H}_4\text{N}$ requires C, 41.2; H, 5.4; N, 10.7%).

(b) *From 2-nitroethyl nitrate.* 2-Nitroethyl nitrate (13.6 g.; Levy, Scaife, and Wilder-Smith, *J.*, 1946, 1096) was added dropwise to a well-stirred solution of sodium hydrogen sulphite (20.8 g.) in water (40 c.c.) at -5° to 0° and stirring was continued for 24 hours at 20° . 2-Nitroethyl nitrate (3.2 g.) was recovered from the solution by ether extraction, and the aqueous layer, after evaporation and extraction as described in (a) above, gave the nitro-sulphonic acid, characterised as its *p*-toluidine salt, in 50% yield.

2-Aminoethanesulphonic Acid.—The nitro-sulphonic acid (above) (1.77 g.) in water (30 c.c.) was shaken with hydrogen and Raney nickel at ordinary temperature and pressure. The filtered solution was evaporated to dryness, treated with concentrated hydrochloric acid, filtered, and again evaporated. The residue on crystallisation from aqueous alcohol afforded 2-aminoethanesulphonic acid (taurine), m. p. 317° (decomp.), in 65% yield. Cortese (*J. Amer. Chem. Soc.*, 1936, 58, 191) gives m. p. $300-305^{\circ}$ (decomp.) (Found: C, 19.2; H, 5.6; N, 10.9. Calc. for $\text{C}_2\text{H}_5\text{O}_2\text{NS}$: C, 19.2; H, 5.6; N, 11.2%).

Sodium 1-Nitropropane-2-sulphonate.—(a) *From sodium hydrogen sulphite.* The salt was prepared from 1-nitroprop-1-ene (17.4 g.; this series, Part I) and sodium hydrogen sulphite (20.8 g.) in water (50 c.c.) as described above for sodium 2-nitroethane sulphonate. Sodium 1-nitropropane-2-sulphonate monohydrate separated from alcohol in 78% yield (Found: C, 17.4; H, 4.1; N, 7.0. $\text{C}_3\text{H}_7\text{O}_2\text{NSNa}\cdot\text{H}_2\text{O}$ requires C, 17.2; H, 3.8; N, 6.7%). The *p*-toluidine salt had m. p. $164-166^{\circ}$ (Found: C, 43.8; H, 5.8; N, 10.2. $\text{C}_8\text{H}_9\text{O}_2\text{NS}_2\text{C}_6\text{H}_4\text{N}$ requires C, 43.5; H, 5.8; N, 10.2%).

(b) *From sulphurous acid.* 1-Nitroprop-1-ene (10 g.) was shaken in a stoppered bottle at room temperature for 2 days with an aqueous solution of sulphurous acid (saturated at 0°). The solution was neutralised with sodium carbonate, evaporated to dryness at 40° under reduced pressure, and the residue extracted with hot absolute alcohol to give sodium 1-nitropropane-2-sulphonate, characterised as the *p*-toluidine salt, m. p. $164-166^{\circ}$.

(c) *From sodium sulphite.* 1-Nitroprop-1-ene (8.7 g.) was gradually added to a vigorously-stirred solution of sodium sulphite heptahydrate (25.2 g.) in water (25 c.c.) at $0-5^{\circ}$ and stirring continued for a further 3 hours at $0-5^{\circ}$ and at 20° for 16 hours. The solution was evaporated to dryness and the residue extracted with absolute alcohol to give disodium 1-aci-nitropropane-2-sulphonate trihydrate, which separated from aqueous alcohol in white crystals (Found: C, 13.6; H, 4.0; N, 5.3. $\text{C}_3\text{H}_6\text{O}_2\text{NSNa}_2\cdot 3\text{H}_2\text{O}$ requires C, 13.6; H, 4.1; N, 5.2%). It was characterised as its *p*-toluidine salt, m. p. $164-166^{\circ}$ alone and in admixture with the sample prepared under (a) above.

1-Aminopropane-2-sulphonic Acid.—The nitro-sulphonic acid (above) was reduced with hydrogen and Raney nickel as described for 2-aminoethanesulphonic acid. The amino-acid, obtained in 79% yield, had m. p. $290-295^{\circ}$ (decomp.) (Gabriel and Colman, *Ber.*, 1906, 39, 2891, give m. p. $290-295^{\circ}$) (Found: C, 25.7; H, 6.5; N, 10.6. Calc. for $\text{C}_3\text{H}_7\text{O}_2\text{NS}$: C, 25.9; H, 6.5; N, 10.1%).

Sodium 2-Nitropropane-1-sulphonate.—(a) *From 2-nitroprop-1-ene.* This was prepared from 2-nitroprop-1-ene (this series, Part I) and sodium hydrogen sulphite as described for sodium 1-nitropropane-2-sulphonate. The salt was crystallised from absolute alcohol, giving sodium 2-nitropropane-1-sulphonate in 88% yield (Found: C, 18.7; H, 4.1; N, 7.0. $\text{C}_3\text{H}_7\text{O}_2\text{NSNa}$ requires C, 18.8; H, 3.1; N, 7.8%).

Catalytic reduction of the salt in the usual way afforded a 60% yield of 2-aminopropane-1-sulphonic acid, which separated from aqueous alcohol, m. p. $325-335^{\circ}$ (decomp.); Gabriel and Ohle (*Ber.*, 1906, 39, 2891) give m. p. 323° (decomp.) (Found: C, 25.9; H, 6.7; N, 10.0. Calc. for $\text{C}_3\text{H}_7\text{O}_2\text{NS}$: C, 25.9; H, 6.5; N, 10.1%).

(b) *From 2-nitropropyl acetate.* A mixture of 2-nitropropyl acetate (7.35 g.; Blomquist, Tapp, and Johnson, *J. Amer. Chem. Soc.*, 1945, 67, 1519), sodium hydrogen sulphite (20.8 g.), and water (50 c.c.) was stirred vigorously at 35° for 16 hours. The homogeneous solution was evaporated to dryness and extracted with absolute alcohol. Evaporation of the alcohol gave a mixture of sodium acetate and sodium 2-nitropropane-1-sulphonate, which was reduced with hydrogen and nickel in the usual way, giving 2-aminopropane-1-sulphonic acid, m. p. $325-328^{\circ}$ (decomp.).

Sodium 1-Nitro-2-methylpropane-2-sulphonate.—(a) *Using sodium hydrogen sulphite.* This reaction was carried out in the normal way using 1-nitro-2-methylprop-1-ene (Levy and Scaife, in the press) in place of the nitropropenes as described above. Recrystallisation from alcohol gave sodium 1-nitro-2-methylpropane-2-sulphonate monohydrate in 95% yield (Found: C, 22.3; H, 4.2; N, 6.1. $\text{C}_4\text{H}_9\text{O}_2\text{NSNa}\cdot\text{H}_2\text{O}$ requires C, 21.5; H, 4.5; N, 6.3%).

(b) *Using sulphurous acid.* The nitro-olefin (10.1 g.) was shaken for 5 days at room temperature in a stoppered bottle with aqueous sulphurous acid (100 c.c. saturated at 0°) in an atmosphere of nitrogen. The solution was neutralised with sodium carbonate and worked up in the normal manner, giving sodium 1-nitro-2-methylpropane-2-sulphonate in 55% yield. In a parallel experiment in which the sulphurous acid solution had been prepared in the presence of air, the only isolated product was sulphamic acid, m. p. 212° (decomp.), obtained in 31% yield, identical with an authentic specimen (Found: H, 3.0; N, 14.3; S, 32.6. Calc. for $\text{H}_2\text{O}_2\text{NS}$: H, 3.1; N, 14.4; S, 33.0%).

1-Amino-2-methylpropane-2-sulphonic Acid.—The nitrosulphonic acid (above) (5 g.) in water (50 c.c.) was reduced with hydrogen and Raney nickel, and the product isolated as described for 2-aminoethanesulphonic acid. **2-Amino-2-methylpropane-2-sulphonic acid** separated from aqueous alcohol as colourless crystals, m. p. 350—360° (decomp.), in 75% yield (Found: C, 31.0; H, 7.2; N, 8.8. $C_4H_9O_2NS$ requires C, 31.3; H, 7.2; N, 9.1%).

Sodium 2-Nitrobutane-3-sulphonate.—2-Nitrobut-2-ene (50.5 g.; this series, Part III) was added dropwise to a cooled solution of sodium hydrogen sulphite (52 g.) in water (120 c.c.). The reaction was carried out in an atmosphere of nitrogen, and stirring was continued for 16 hours. Unreacted 2-nitrobut-2-ene was removed by extraction with ether, the aqueous solution evaporated to dryness under reduced pressure, and the residue extracted with absolute alcohol from which, by evaporation, a pale yellow viscous syrup (80 g.) was obtained. A crystalline solid (10 g.) (see below) separated from this syrup on standing. The syrup, apparently crude sodium 2-nitrobutane-3-sulphonate, gave a *p*-toluidine salt which decomposed below its melting point (Found: C, 45.5; H, 5.8; N, 9.1. $C_8H_{11}O_2NS.C_7H_7N$ requires C, 45.5; H, 6.2; N, 9.6%). Reduction of the syrup with Raney nickel and hydrogen, followed by isolation in the usual way, gave 2-aminobutane-3-sulphonic acid, m. p. 267—270°, in 60% yield (Found: C, 31.3; H, 6.9; N, 9.5. $C_4H_9O_2NS$ requires C, 31.4; H, 7.2; N, 9.2%). The crystalline solid (above) could not be identified with certainty. It may be sodium 2-oximinobutane-3-sulphonate (Found: C, 24.7; H, 4.4; N, 7.4. Calc. for $C_4H_9O_2NSNa$: C, 25.4; H, 4.2; N, 7.4%). The *p*-toluidine salt had m. p. 186—188° (Found: C, 47.1; H, 6.6; N, 10.4. Calc. for $C_8H_{11}O_2NS.C_7H_7N$: C, 48.1; H, 6.6; N, 10.2%). On reduction with hydrogen and Raney nickel in the usual way it gave an amino-acid, m. p. 320—324° (decomp.), in 60% yield (Found: C, 30.6; H, 6.8; N, 9.0. Calc. for $C_4H_9O_2NS$: C, 31.4; H, 7.2; N, 9.2%).

2-Nitro-4-methylpent-2-ene.—To a cooled mixture of isobutaldehyde (36 g.) and diethylamine (10 g.), nitroethane (37.5 g.) was added during 30 minutes, the temperature being kept at 20—30° by intermittent cooling. The mixture was kept at 20° for 15 hours, acidified (2*N*-hydrochloric acid), extracted with ether, and the dried extract fractionated, giving 2-nitro-4-methylpent-2-ene (40.5 g.; 65%, b. p. 67°/10 mm.), as a pale yellow lachrymatory oil (Found: C, 56.2; H, 8.1; N, 10.9. $C_6H_{11}O_2N$ requires C, 55.8; H, 8.5; N, 10.8%).

2-Amino-4-methylpentane-3-sulphonic Acid.—2-Nitro-4-methylpent-2-ene (12.9 g.) in methyl alcohol (35 c.c.) was added dropwise with stirring to a solution of sodium hydrogen sulphite (24 g.) in water (100 c.c.) and methyl alcohol (35 c.c.) at 20°. The mixture was maintained at 30° for 16 hours, evaporated, and extracted with hot absolute alcohol. Concentration of this extract yielded crude sodium 2-nitro-4-methylpentane-3-sulphonate as a pale yellow viscous syrup (yield, 99%), which could not be crystallised. Reduction in aqueous solution with Raney nickel and hydrogen at 25° and 100 atms. (initial pressure) gave 2-amino-4-methylpentane-3-sulphonic acid, white crystals from aqueous alcohol, decomp. > 340°, in 75% yield (Found: C, 40.0; H, 8.3; N, 7.7. $C_6H_{11}O_2NS$ requires C, 39.7; H, 8.3; N, 7.7%).

Sodium 1-Nitro-2-phenylethane-2-sulphonate and 1-Amino-2-phenylethane-2-sulphonic Acid.—(a) *From sodium hydrogen sulphite.* A solution of 2-nitrostyrene (14.9 g.) in dioxan (60 c.c.) was added slowly to a well-stirred solution of sodium hydrogen sulphite (15 g.) in water (90 c.c.) at 20°, and stirring then continued at 30° for 10 hours. Unchanged nitrostyrene was removed with ether, and the aqueous dioxan solution evaporated to dryness. The residue was crystallised from hot absolute alcohol, giving sodium 1-nitro-2-phenylethane-2-sulphonate as white crystals, unmolten at 300°, in 80% yield (Found: N, 5.2. $C_8H_9O_2NSNa$ requires N, 5.5%). Reduction in aqueous solution with Raney nickel and hydrogen at ordinary temperature and pressure, followed by working up in the normal way, afforded 1-amino-2-phenylethane-2-sulphonic acid in 70% yield, pearly plates from aqueous alcohol, m. p. 358—360° (decomp.) (Found: C, 47.1; H, 5.3; N, 7.0. $C_8H_9O_2NS$ requires C, 47.7; H, 5.5; N, 7.0%).

(b) *From sulphurous acid.* 2-Nitrostyrene (10 g.) was shaken with saturated aqueous sulphurous acid (100 c.c.) in a stoppered bottle in the absence of oxygen for 6 days at room temperature. The unreacted nitrostyrene (2.0 g.) was removed by filtration and the solution neutralised with solid sodium carbonate. The crude nitro-acid was reduced with Raney nickel and hydrogen, giving the amino-acid, m. p. 358—360° (decomp.), in 56% yield.

Sodium 1-Nitro-2-(2-furyl)ethane-2-sulphonate.—1-Nitro-2-(2-furyl)ethylene (13.9 g.; Thiele and Landers, *Annalen*, 1909, **369**, 303) in dioxan (50 c.c.) was slowly added to a stirred solution of sodium hydrogen sulphite (24 g.) in water (100 c.c.) and dioxan (50 c.c.) at 25°, and stirring continued for a further 16 hours. The solution was evaporated to dryness, and the residue, extracted with absolute alcohol, gave sodium 1-nitro-2-(2-furyl)ethanesulphonate as a colourless syrup which crystallised slowly on keeping, but could not be recrystallised (Found: C, 26.2; H, 4.2; N, 5.4. $C_8H_9O_2NSNa.2H_2O$ requires C, 25.8; H, 3.6; N, 5.0%). Reduction with Raney nickel and hydrogen in methyl alcohol at ordinary temperature and pressure gave 1-amino-2-(2-furyl)ethane-2-sulphonic acid, white crystals from aqueous dioxan, m. p. 250—252° (decomp.), in 30% yield (Found: N, 7.0. $C_8H_9O_2NS$ requires N, 7.3%).

1-Amino-1-carbethoxy-2-methylpropane-2-sulphonic Acid.—Ethyl α -nitro- $\beta\beta$ -dimethylacrylate (5 g.; Bouveault and Wahl, *Compt. rend.*, 1900, **131**, 687, 748) was added dropwise to a vigorously stirred solution of sodium hydrogen sulphite (5 g.) in water (20 c.c.) at 30°, and stirring was continued for a further 20 hours. The solution was evaporated under reduced pressure and extracted with hot absolute alcohol to give crude sodium 1-nitro-1-carbethoxy-2-methylpropane-2-sulphonate as a colourless glass in 84% yield. Reduction of the above salt (6.7 g.) in water (60 c.c.) with Raney nickel and hydrogen at ordinary temperature and 90 atms. (initial pressure), followed by evaporation of the filtered solution, afforded sodium 1-amino-1-carbethoxy-2-methylpropanesulphonate, white crystals from aqueous alcohol, in 45% yield (Found: N, 5.4. $C_5H_9O_2NSNa$ requires N, 5.7%). Acidification of an aqueous solution of the sodium salt with concentrated hydrochloric acid gave the free amino-sulphonic acid, white crystals from aqueous alcohol, m. p. 223°, in 34% yield (Found: N, 6.0. $C_5H_9O_2NS$ requires N, 6.2%).

Sodium 1-Nitro-2:4:4-trimethylpentane-2-sulphonate.—A mixture of 1-nitro-2:4:4-trimethylpent-1-ene (5 g.; see Levy, Scaife, and Baldock, in the press), dioxan (15 c.c.), and saturated aqueous sodium hydrogen sulphite (50 c.c.) was stirred at 20° for 8 hours. After concentration under reduced

pressure at 20°, the residual white solid was extracted with alcohol, filtered, and the extract treated with dry ether. A white crystalline salt was precipitated, and purified by reprecipitation from alcohol with ether. Sodium 1-nitro-2:4:4-trimethylpentane-2-sulphonate was obtained as white crystals, m. p. 189° (decomp.) (Found: N, 5.4; S, 12.8. $C_8H_{16}O_8NSNa$ requires N, 5.4; S, 12.3%).

285. Aliphatic Nitro-compounds. Part VI. Reaction of α -Nitro-olefins with Hydrochloric Acid.

By ROYDEN L. HEATH and J. D. ROSE.

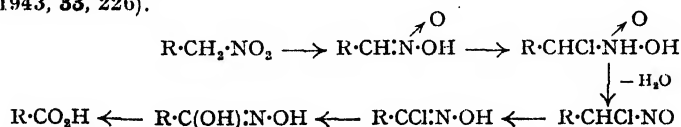

α -Nitro-olefins react with anhydrous hydrogen chloride in ether giving 1:2-dichloronitroso-compounds which rearrange, if an α -hydrogen atom is present, into 1:2-dichloro-oximes. These on hydrolysis with water afford hydroxylamine hydrochloride and an α -hydroxy- or α -chloro-carboxylic acid according to the extent of the hydrolysis. Reaction of the nitro-olefins containing an α -hydrogen atom with concentrated aqueous hydrochloric acid gives similar products, but the intermediate dichloro-oximes are not isolated. It is suggested that the initial step is a 1:4-addition of hydrogen chloride to the nitro-olefin.

THE literature on the action of hydrochloric acid on α -nitro-olefins is scanty. Haitinger (*Monatsh.*, 1881, 2, 287; *Wien Akad. Ber.*, 1878, 77, 428; *A.*, 1879, 700) reported that 1-nitro-2-methylprop-1-ene, treated with hydrogen chloride at 20° or with boiling concentrated hydrochloric acid, gave hydroxylamine hydrochloride, carbon dioxide, and ammonia; a hydroxy-acid, m. p. 65°, was also isolated but not characterised. Our experience, below, suggests that this was probably impure α -hydroxyisobutyric acid (m. p. 79—80°). Priebis (*Annalen*, 1884, 225, 319) obtained phenylchloroacetic acid by treatment of β -nitrostyrene with fuming hydrochloric acid at 100°.

A study of the action of hydrochloric acid on α -nitro-olefins was undertaken as part of a general exploration of the chemistry of the aliphatic nitro-compounds. In the case of nitro-olefins with an α -hydrogen atom ($R_2C:CH:NO_2$), treatment with ethereal hydrogen chloride gave hydroxylamine hydrochloride and an α -chloro- or α -hydroxy-acid (cf. Priebis, *loc. cit.*).

The possibility that the first stage in the reaction was 1:2-addition of hydrogen chloride to the double bond was excluded when it was found that 2-nitroisopropyl chloride, $Me\cdot CHCl\cdot CH_2\cdot NO_2$, was not affected by ethereal hydrogen chloride under the conditions which converted 1-nitroprop-1-ene, $Me\cdot CH_2\cdot CH:NO_2$, into α -chloropropionic acid and hydroxylamine

hydrochloride. It therefore follows that the first addition is 1:4- to give $R_2CCl:CH:N\cdot OH$, which, as the *aci*-form of a primary nitro-paraffin, breaks down *via* the hydroxamic acid to hydroxylamine hydrochloride and an α -chloro- or α -hydroxy-acid (depending on the lability of the chlorine atom). The mechanism of conversion of the *aci*-primary nitro-paraffin into hydroxamic acid is still obscure but is considered to involve the following steps (cf. Yale, *Chem. Reviews*, 1943, 33, 226).

In this mechanism, an important stage is the rearrangement of the 1-chloronitroso-compound to an oxime, which requires a hydrogen atom on the carbon carrying the nitroso-group. From secondary nitro-paraffins, in which this hydrogen is not available, the product expected would therefore be a 1-chloronitroso-compound or its breakdown products. In agreement with this we have found that treatment of nitro-olefins of the type $RR'C:CR''\cdot NO_2$ with ethereal hydrochloric acid gives deep blue highly lachrymatory liquids. Although it has not been possible to obtain these analytically pure on account of the closeness of their boiling points to those of the parent nitro-olefins, there seems little doubt that these are the dichloronitroso-compounds.

Attempts to break down these dichloronitroso-compounds by further treatment with hydrochloric acid gave a trace of hydroxylamine hydrochloride as the only product identified.

EXPERIMENTAL.

Action of Anhydrous Hydrogen Chloride on Nitroethylene.—Nitroethylene (37 g.; this series, Part I) was added dropwise to stirred saturated ethereal hydrogen chloride (300 c.c.) below 0°. Stirring was continued at 0° for 4 hours and at 20° for a further 12 hours. After removal of the ether under reduced pressure $\alpha\beta$ -dichloroacetaldoxime remained as a colourless mobile liquid which began to decompose immediately. The crude product was stirred with water (300 c.c.) at 20° for 16 hours; the mixture, which was homogeneous, still gave a positive test for a hydroxamic acid and was refluxed for $\frac{1}{2}$ hour (hydroxamic acid test negative) and evaporated to dryness under reduced pressure. The residue was extracted with ether, giving chloroacetic acid (39 g.; 82%), m. p. 62–63°, after recrystallisation from chloroform, and hydroxylamine hydrochloride (31.5 g.; 90%) as the ether-insoluble product.

Action of Concentrated Hydrochloric Acid on 2-Nitroethyl Alcohol.—2-Nitroethyl alcohol (10 g.; Levy, Scaife, and Wilder-Smith, J., 1946, 1096) was heated at 140° for 12 hours with concentrated hydrochloric acid (80 c.c.) in a sealed tube. The solution was evaporated and separated by ether into chloroacetic acid (6.2 g.; 60%) and hydroxylamine hydrochloride (5.3 g.; 70%).

Action of Anhydrous Hydrogen Chloride on 1-Nitroprop-1-ene.—This was carried out using 1-nitroprop-1-ene (51 g.; this series, Part I) and ethereal hydrogen chloride (250 c.c.) as described above for nitroethylene. The $\alpha\beta$ -dichloropropaldoxime was distilled (80%), b. p. 78–80°/12 mm., but began to decompose immediately after distillation. A portion (37 g.) was hydrolysed by refluxing it with water (100 c.c.) for $\frac{1}{2}$ hour. After evaporation the residue was separated by ether into lactic acid (8.0 g.; 33%), α -chloropropionic acid (0.7 g.; 2%), and hydroxylamine hydrochloride (10.4 g.; 60%).

Action of Concentrated Hydrochloric Acid on 1-Nitroprop-1-ene and 2-Nitroisopropyl Alcohol.—1-Nitroprop-1-ene (20 g.) was stirred with concentrated hydrochloric acid (100 c.c.) at 20° for 24 hours and then at 40° for 2 hours. After working up in the usual way, hydroxylamine hydrochloride (12 g.; 75%), lactic acid (6.0 g.; 30%), and α -chloropropionic acid (0.5 g.; 2%) were obtained. Similarly, 2-nitroisopropyl alcohol (10.5 g.) heated at 140° for 2 hours with concentrated hydrochloric acid (sealed tube) gave hydroxylamine hydrochloride (5.3 g.; 75%) and α -chloropropionic acid (5.6 g.; 54%).

Action of Anhydrous Hydrogen Chloride on 2-Nitroprop-1-ene.—2-Nitroprop-1-ene (26.1 g.; this series, Part I) was added dropwise with stirring to dry ether saturated at 0° with anhydrous hydrogen chloride (200 c.c.); a deep blue colour rapidly developed. Stirring was continued at 0° and precipitated hydroxylamine hydrochloride (1.8 g.) removed. Separated water was absorbed by the addition of anhydrous magnesium sulphate, and the solution distilled giving 1:2-dichloro-2-nitrosopropane, b. p. 48–50°/60 mm., as a deep blue, mobile, powerfully lachrymatory liquid (20 g.; 45%). It was not possible to obtain this material analytically pure owing to difficulties of separating small amounts of unchanged 2-nitroprop-1-ene (b. p. 45–48°/60 mm.).

Action of Anhydrous Hydrogen Chloride on 2-Nitrobut-2-ene.—2-Nitrobut-2-ene (20.2 g.; this series, Part III) was treated as described above for 2-nitroprop-1-ene. 2:3-Dichloro-2-nitrosobutane, b. p. 61–63°/40 mm., was obtained as a deep blue lachrymatory liquid (11 g.; 35%). After hydrolysis with water at 20° for 16 hours only hydroxylamine hydrochloride (0.1 g.) could be identified.

Action of Concentrated Hydrochloric Acid on 2-Nitrobut-2-ene.—2-Nitrobut-2-ene (20 g.) was stirred at 20° for 40 hours with concentrated hydrochloric acid (100 c.c.). The deep blue colour which developed initially disappeared in $\frac{1}{2}$ hour. Evaporation to dryness under reduced pressure gave only hydroxylamine hydrochloride (7 g.; 52%).

Action of Anhydrous Hydrogen Chloride on 1-Nitro-2-methylprop-1-ene.—1-Nitro-2-methylprop-1-ene (60 g.; Levy and Scaife, in the press) was treated with saturated ethereal hydrogen chloride (400 c.c.) as described above for nitroethylene. $\alpha\beta$ -Dichloroisobutaldoxime, b. p. 79°/10 mm., was obtained as a colourless liquid which began to decompose immediately after distillation (75 g.; 80%). Hydrolysis of this dichloro-oxime (24 g.) with boiling water (250 c.c.) for 16 hours gave hydroxylamine hydrochloride (9.5 g.; 90%) and α -hydroxyisobutyric acid, m. p. 80° (4.8 g.; 30%). Hydrolysis of the dichloro-oxime with concentrated hydrochloric acid for $1\frac{1}{2}$ hours gave a 50% yield of α -hydroxyisobutyric acid.

Action of Concentrated Hydrochloric Acid on 1-Nitro-2-methylprop-1-ene.—1-Nitro-2-methylprop-1-ene (20.2 g.) was added dropwise with vigorous stirring to concentrated hydrochloric acid (100 c.c.) at 15–20°. Stirring was continued for 16 hours, and the mixture then boiled for 15 minutes and worked up in the usual way, giving hydroxylamine hydrochloride (12 g.; 86%) and α -hydroxyisobutyric acid (11.3 g.; 54%).

Action of Anhydrous Hydrogen Chloride on 1-Nitro-2-chloropropane.—1-Nitro-2-chloropropane (Henry, Bull. Soc. chim., 1895, 13, 1000) was treated with anhydrous ethereal hydrogen chloride under the conditions described for 1-nitroprop-1-ene (see above). On distillation unchanged 1-nitro-2-chloropropane, b. p. 60–65°/14 mm., was recovered quantitatively.

IMPERIAL CHEMICAL INDUSTRIES LIMITED, RESEARCH LABORATORIES,

HEXAGON HOUSE, BLACKLEY, MANCHESTER, 9.

[Received, January 23rd, 1947.]

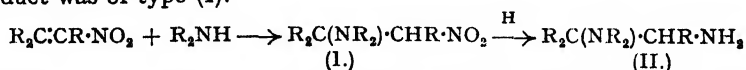

286. Aliphatic Nitro-compounds. Part VII. Preparation of 2-Nitroalkylamines.

By R. L. HEATH and J. D. ROSE.

Ammonia and primary or secondary amines interact with α -nitro-olefins, giving 2-nitroalkylamines. Those formed from ammonia or aliphatic amines are in general extremely unstable, but can be reduced by nickel and hydrogen to derivatives of ethylenediamine. N-2-Nitroalkylarylamines formed from aromatic amines are somewhat more stable, but are best isolated and characterised through their salts. In many cases 2-nitroethyl nitrate can be

used as a convenient laboratory substitute for nitroethylene, and 2-nitroisopropyl acetate or 2-nitroisopropyl nitrate can replace 1-nitroprop-1-ene.

THE addition of ammonia and amines to α -nitro-olefins has hitherto received only scant attention in the literature. The reaction of nitroethylene with aniline (Wieland and Sakellarios, *Ber.*, 1919, 52, 898) and nuclear substituted anilines (Kodak Ltd., B.P. 539,070; 21.2.40) is known to give *N*-2-nitroethylanilines, but in most cases the products were not characterised and experimental details are lacking. β -Nitrostyrene reacts with hydroxylamine to give $\text{Ph}\cdot\text{CH}(\text{NH}\cdot\text{OH})\cdot\text{CH}_2\cdot\text{NO}_2$ (Posner, *Annalen*, 1912, 389, 114), but the reaction with other bases is erratic. Worrall (*J. Amer. Chem. Soc.*, 1927, 49, 1598) attempted to add some forty bases (amines, hydrazines) to β -nitrostyrene and found that only thirteen gave isolatable adducts. Aniline and *p*-toluidine were the only common aromatic bases and piperidine the only secondary amine with which he was able to obtain an adduct, and in each of these three cases the adduct was of type (I).

The addition of ammonia was, however, exceptional, two mols. of β -nitrostyrene being involved to give $\text{NH}(\text{CHPh}\cdot\text{CH}_2\cdot\text{NO}_2)_2$.

Halogen-substituted nitro-olefins have also been reported to react with amines. Thus β -bromo- β -nitrostyrene with ammonia gives 2-bromo-2-nitro-1-phenylethylamine (Loevenich and Gerber, *Ber.*, 1930, 63, 1707), and 1-bromo-1-nitrobut-1-ene with aliphatic amines gives unstable adducts (Loevenich, Koch, and Pucknat, *Ber.*, 1930, 63, 636).

A study of the addition of amines to nitro-olefins has now been undertaken as part of a general investigation of the aliphatic nitro-compounds and as a possible route to certain substituted derivatives of ethylenediamine required for other work.

The addition of ammonia and amines to nitro-olefins is a general reaction which in most cases proceeds very readily. The yields are variable, but this is due to the instability of the resulting 2-nitroalkylamine in which the basic group causes rapid decomposition of the primary or secondary nitro-compound. The products from aromatic amines are weaker bases than those from ammonia or aliphatic amines and are therefore more stable, but in both series it was found preferable to isolate the adducts as salts. Hydrogenation of the 2-nitroalkylamines to ethylenediamines was carried out using Raney nickel.

A complication in carrying out these additions was the tendency of the nitro-olefins to polymerise under the influence of the amine. It was found that better yields of some adducts were obtained when esters of the corresponding 2-nitro-alcohols were used in place of the nitro-olefin. Thus 2-nitroethyl nitrate and 2-nitroisopropyl acetate could be used to replace nitroethylene and 1-nitroprop-1-ene, respectively.

Ammonia has been caused to react with 2-nitroethyl nitrate, 1-nitroprop-1-ene, 2-nitrobut-2-ene, and 1-nitro-2-methylprop-1-ene to give the corresponding unstable β -nitro-amines (type I) which were characterised as salts. Hydrogenation of the nitro-amines over Raney nickel gave the 1:2-diamines (type II). Similarly, diethylamine reacted with 2-nitroethyl nitrate and 2-nitrobut-2-ene to give nitro-amines (type I). From 1:2:3:4-tetrahydroquinoline, the *N*-2-nitroethyl derivative was obtained in 75% yield from 2-nitroethyl nitrate, but in only 12.5% yield from nitroethylene itself.

Aniline has been caused to react with nitroethylene, 2-nitroethyl nitrate, 1-nitroprop-1-ene, and 2-nitrobut-2-ene; *N*-methylaniline with nitroethylene, 1-nitroprop-1-ene, and 2-nitroisopropyl acetate; *N*-ethylaniline with nitroethylene, 2-nitroethyl nitrate, and 1-nitroprop-1-ene. All the products were of type I and readily reverted to nitro-olefin and amine on treatment with alkali (which polymerised the nitro-olefin formed), and in some cases dilute acid affected the same fission. A bis-adduct, *di*-(2-nitroethyl)aniline, was isolated as its hydrochloride after further reaction of *N*-2-nitroethylaniline with nitroethylene; this salt eliminated nitroethylene on being heated in water. There was evidence that 2-nitroethylaniline reacted with 1-nitroprop-1-ene, but the product was too unstable for isolation.

EXPERIMENTAL.

Analyses are by Mr. E. S. Morton. M. ps. are uncorrected.

2-Nitroethylamine and Ethylenediamine.—2-Nitroethyl nitrate (13.6 g.; Levy, Scaife, and Wilder-Smith, *J.*, 1946, 1096) was added dropwise with stirring to methyl alcohol (200 c.c.) saturated with dry ammonia at -5° , and stirring continued for 4 hours at -5° to 0° . The mixture was filtered and the filtrate evaporated at 40° under reduced pressure to give a light brown oil (9 g.). The crude 2-nitro-

ethylamine could not be distilled, did not give a crystalline hydrochloride or picrate, and decomposed to a black tar in 1 to 2 hours. The crude product (8 g.) in methyl alcohol (300 c.c.) was shaken with hydrogen and Raney nickel at ordinary temperature and pressure; the hydrogen absorption was almost theoretical. The mixture was filtered, acidified with hydrochloric acid, and evaporated to dryness; the semi-solid crystalline mass was intimately mixed with powdered potassium hydroxide and dry distilled to give an aqueous solution of ethylenediamine (5.4 g.), b. p. 100–110°; the dipicrate, m. p. 232–234° (decomp.), was identical with an authentic specimen.

2-Nitroisopropylamine.—1-Nitroprop-1-ene (30 g.; this series, Part I) was added with stirring to methyl-alcoholic ammonia (200 c.c.) at 0° and stirring continued for 3 hours. The solution was evaporated and distilled, giving 2-nitroisopropylamine, b. p. 50–55°/10 mm. Yield, 55%. 2-Nitroisopropylamine is very unstable and decomposes in 24 hours. The hydrochloride had m. p. 114° (Found: C, 26.0; H, 6.4; Cl, 25.5. $C_3H_7O_2N_2.HCl$ requires C, 25.6; H, 6.4; Cl, 25.3%).

1:2-Diaminopropane.—The nitroamine (above) (10 g.) in methyl alcohol (400 c.c.) was shaken with hydrogen in the presence of Raney nickel at ordinary temperature and pressure. The theoretical amount of hydrogen was absorbed. The solution was filtered, acidified with concentrated hydrochloric acid, and evaporated to dryness at 40° under reduced pressure to give 1:2-diaminopropane dihydrochloride which crystallised in long needles from alcohol-ether, m. p. 221° (Strache, *Ber.*, 1888, 21, 2359, gives m. p. 220°). Yield, 52%. The dipicrate formed yellow needles from water, m. p. 237° (Windaus, Dorries, and Jensen, *Ber.*, 1921, 54, 2750, give m. p. 237°).

Di-(2-nitroisopropyl)amine.—Dry ammonia was passed for 1 hour through a solution of 2-nitroisopropyl nitrate (30 g.; Levy and Scaife, *J.*, 1946, 1100) in dry ether (200 c.c.). The solution, filtered from ammonium nitrate (15.7 g.), was fractionated, giving *di*-(2-nitroisopropyl)amine, b. p. 60–62°/0.5 mm. Yield, 12.7 g. (Found: N, 21.6. $C_6H_{13}O_4N_4$ requires N, 22.0%).

2-Nitro-3-aminobutane.—2-Nitrobut-2-ene (20.2 g.; this series, Part III) was added dropwise with stirring to methyl-alcoholic ammonia (250 c.c.) at 0° and stirring continued for 2 hours. The solution was evaporated and distilled, giving 2-nitro-3-aminobutane as an almost colourless liquid, b. p. 75–78°/20 mm., n_D^{20} 1.4720 (60%), which decomposed in 2 days. The hydrochloride, m. p. 115° (decomp.), was also unstable (Found: Cl, 23.4. $C_4H_{10}O_2N_2.HCl$ requires Cl, 23.0%).

2:3-Diaminobutane.—2-Nitro-3-aminobutane (6 g.) in methyl alcohol (60 c.c.) was shaken with hydrogen in the presence of Raney nickel. When absorption was complete the solution was filtered, acidified with hydrochloric acid, evaporated to dryness, and the crystalline residue of the dihydrochloride recrystallised from aqueous alcohol to m. p. 312°. Yield, 40% (Found: C, 20.8; H, 8.2; N, 17.4. $C_4H_{12}N_2.2HCl$ requires C, 20.8; H, 8.7; N, 17.4%). Angeli (*Ber.*, 1890, 23, 1357) reports that the dihydrochloride of 2:3-diaminobutane is crystalline, but gives no m. p. The picrate decomposed at 250–252° (Morgan and Hickinbottom, *J. Soc. Chem. Ind.*, 1924, 43, 3097, give m. p. 250–252°).

1-Nitro-2-amino-2-methylpropane.—Dry ammonia was passed into a solution of 1-nitro-2-methylprop-1-ene (Levy and Scaife, in the press) in dry benzene (100 c.c.) at 20° for 8 hours, and the solution then distilled giving 1-nitro-2-amino-2-methylpropane as an oil, b. p. 62–65°/11 mm., in 40% yield. The nitroamine was unstable and decomposed in 3–4 days. The hydrochloride, from absolute alcohol, had m. p. 182° (decomp.) (Found: N, 18.1; Cl, 22.9. $C_4H_{10}O_2N_2.HCl$ requires N, 18.1; Cl, 23.0%). Reduction of the nitroamine with Raney nickel and hydrogen afforded 1:2-diamino-2-methylpropane isolated in 75% yield as the dihydrochloride, m. p. 302°. Strack and Schwaneberg (*Ber.*, 1933, 66, 1333) give m. p. 303° (Found: Cl, 44.2. Calc. for $C_4H_{12}N_2.2HCl$: Cl, 44.1%).

Diethyl-2-nitroethylamine.—2-Nitroethyl nitrate (6.8 g.) was added dropwise with stirring to diethylamine (7.3 g.) in dry ether (100 c.c.) kept at 0° by external cooling. After the addition was complete, stirring was continued for $\frac{1}{2}$ hour. The solution was filtered and the ether removed at 20° under reduced pressure. An attempt to distil a small portion of the residue at 15 mm. was unsuccessful; the product decomposed violently. The hydrochloride, from alcohol-ether, had m. p. 72–75° (Found: Cl, 19.3. $C_6H_{14}O_2N_2.HCl$ requires Cl, 19.4%). The picrate formed needles from alcohol, m. p. 88° (Found: C, 38.6; H, 4.8; N, 18.4. $C_8H_{16}O_4N_4$ requires C, 38.2; H, 5.0; N, 18.5%).

2-Nitro-3-diethylaminobutane.—2-Nitrobut-2-ene (10.1 g.) in dry ether (10 c.c.) was added dropwise with stirring to diethylamine (7.3 g.) in dry ether (25 c.c.) at 0–10° and the mixture stirred for a further 2 hours. The product was fractionated to give 2-nitro-3-diethylaminobutane, b. p. 90–95°/11 mm., in 65% yield. Much decomposition had occurred after 12 hours. The picrolonate had m. p. 267° (decomp.) (Found: C, 49.4; H, 5.4. $C_{12}H_{24}O_2N_2$ requires C, 49.3; H, 5.9%).

N-(2-Nitroethyl)-1:2:3:4-tetrahydroquinoline.—(a) From 2-nitroethyl nitrate. 2-Nitroethyl nitrate (5.9 g.) was added dropwise with stirring to tetrahydroquinoline (11.8 g.), the temperature being kept below 30°. After 1 hour's stirring the product was dissolved in ether (50 c.c.) and washed with water. Ethereal hydrogen chloride was added to the dried ethereal solution and the precipitated hydrochloride crystallised from absolute alcohol, m. p. 132°. Yield, 75% (Found: N, 11.4; Cl, 14.3. $C_{11}H_{14}O_2N_2.HCl$ requires N, 11.5; Cl, 14.6%).

(b) From nitroethylene. A mixture of equimolecular amounts of nitroethylene and tetrahydroquinoline stirred at 40° for 1 hour gave the base, isolated as the hydrochloride, m. p. 132°, in 12.5% yield.

2-Nitroethylaniline.—(a) From nitroethylene. The base was prepared according to Wieland and Sakellarios (*Ber.*, 1919, 52, 898). Yield, 80%; m. p. 37°.

(b) From 2-nitroethyl nitrate. To a well-stirred solution of aniline (37.2 g.) in ether (250 c.c.), 2-nitroethyl nitrate (27.2 g.) was added dropwise at room temperature. After being stirred for 2 hours the ethereal solution was washed with water, dried, and concentrated under reduced pressure below 30°. The resulting syrup crystallised on cooling strongly, and separated from ether-light petroleum in golden plates, m. p. 37° (22 g.; 65%). The hydrochloride formed needles from alcohol-ether, m. p. 109° (Found: N, 13.9. $C_8H_{10}O_2N_2.HCl$ requires N, 13.8%). The acetyl derivative formed long needles from aqueous alcohol, m. p. 99° (Found: N, 13.2. $C_{10}H_{12}O_3N_2$ requires N, 13.4%).

Di-(2-nitroethyl)aniline.—Nitroethylene (3.7 g.) was added with stirring to 2-nitroethylaniline (8.3 g.) at 0–10°. After 2 hours the product was dissolved in a mixture of acetone (50 c.c.) and ether (50 c.c.), and ethereal hydrogen chloride added. The precipitated hydrochloride separated from dry alcohol

containing hydrogen chloride as prisms, m. p. 128° (7.8 g.; 50%) (Found: Cl, 12.7. $C_{10}H_{13}O_4N_3.HCl$ requires Cl, 12.9%). The free base, m. p. 64°, was obtained by crystallising the hydrochloride from aqueous alcohol (Found: C, 50.0; H, 5.7; N, 17.0. $C_{10}H_{13}O_4N_3$ requires C, 50.2; H, 5.4; N, 17.5%).

Methyl-2-nitroethylaniline.—Nitroethylene (3.6 g.) was added dropwise with stirring to methylaniline (5.3 g.) at 0–10° and the reaction completed by heating at 40° for 1 hour; the product distilled at 110°/0.2 mm. (yield, 4.5 g.; 50%). The hydrochloride had m. p. 82° (Found: N, 12.4; Cl, 16.5. $C_9H_{11}O_2N_3.HCl$ requires N, 12.9; Cl, 16.4%).

Ethyl-2-nitroethylaniline.—(a) From 2-nitroethyl nitrate. The preparation was carried out from ethylaniline and 2-nitroethyl nitrate as described under (b) above for the preparation of 2-nitroethylaniline. The product was isolated in 80% yield as the hydrochloride, m. p. 114° (Found: N, 12.2; Cl, 15.3. $C_{10}H_{14}O_2N_3.HCl$ requires N, 12.2; Cl, 15.4%). The free base was formed by gradual addition of solid sodium carbonate (6.6 g.) to a fine suspension of the hydrochloride (30 g.) in water (100 c.c.) at 0–5°. Ethyl-2-nitroethylaniline separated as a pale green oil which was isolated by ether and distilled, b. p. 108°/0.1 mm., n_D^{20} 1.5597. Yield, 70% (Found: C, 61.8; H, 7.2; N, 14.4. $C_{10}H_{14}O_2N_3$ requires C, 61.8; H, 7.2; N, 14.4%). The picrate, from alcohol, had m. p. 106° (Found: C, 45.9; H, 4.5; N, 16.3. $C_{10}H_{14}O_2N_3.C_6H_3O_7N_3$ requires C, 45.4; H, 4.0; N, 16.5%).

(b) From nitroethylene. The preparation was carried out as described above for the preparation of methyl-2-nitroethylaniline, and the hydrochloride, m. p. 114°, isolated in 75% yield.

2-Nitroisopropylaniline.—This was prepared from 1-nitroprop-1-ene (8.7 g.) and aniline (9.3 g.) in ether (100 c.c.) at room temperature for 2 hours. Removal of the ether under reduced pressure gave a yellow oil which solidified on cooling to –50°, and was crystallised from alcohol, giving yellow needles of 2-nitroisopropylaniline, m. p. 33° (Found: C, 60.05; H, 6.45; N, 15.2. $C_9H_{11}O_2N_3$ requires C, 60.0; H, 6.6; N, 15.5%). The hydrochloride, from 2N-hydrochloric acid, had m. p. 148° (Found: N, 12.8; Cl, 16.6. Calc. for $C_9H_{11}O_2N_3.HCl$: N, 12.9; Cl, 16.4%). Fourncau (*Bull. Soc. chim.*, 1944, 11, 143) gives m. p. 141°.

Methyl-2-nitroisopropylaniline.—(a) From 1-nitroprop-1-ene. Methylaniline (53.5 g.) was added dropwise to well stirred 1-nitroprop-1-ene (43 g.), the temperature being kept below 30° by external cooling. The crude product was dissolved in ether (500 c.c.) and added slowly with stirring to cool ethereal hydrogen chloride (500 c.c. containing 20 g. of hydrogen chloride). The separated solid was triturated twice with methyl alcohol-ether (1 : 2), giving the pure hydrochloride (106 g.; 92%), m. p. 126° (Found: Cl, 15.5. $C_{10}H_{14}O_2N_3.HCl$ requires Cl, 15.3%). The hydrochloride, which is largely hydrolysed in aqueous solution, was treated in water with sodium carbonate, giving a pale green oil, which was isolated with ether and distilled, yielding methyl-2-nitroisopropylaniline, b. p. 112–115°/0.5 mm., in 80% yield (Found: C, 62.3; H, 7.2. $C_{10}H_{14}O_2N_3$ requires C, 61.8; H, 7.2%). The picrate had m. p. 116° (Found: C, 45.3; H, 4.3; N, 16.8. $C_{10}H_{14}O_2N_3.C_6H_3O_7N_3$ requires C, 45.4; H, 4.0; N, 16.6%). The perchlorate formed colourless prisms from alcohol-ether, m. p. 116° (Found: C, 40.3; H, 5.1; N, 9.4. $C_{10}H_{14}O_2N_3.HClO_4$ requires C, 40.7; H, 5.1; N, 9.5%). The hydrochloride of the p-nitroso-derivative, prepared by nitrosation of the hydrochloride, formed dark green crystals from methyl alcohol, and decomposed at 160° (Found: C, 46.4; H, 5.2. $C_{10}H_{13}O_3N_3.HCl$ requires C, 46.2; H, 5.4%).

(b) From 2-nitroisopropyl acetate. A mixture of methylaniline (5.3 g.) and 2-nitroisopropyl acetate (7.4 g.; Schmidt and Rutz, *Ber.*, 1928, 61, 2142) was heated at 50° for 8 hours. The crude product was converted into the hydrochloride, m. p. 126°, which was obtained in 50% yield.

Ethyl-2-nitroisopropylaniline.—This was prepared from 1-nitroprop-1-ene and ethylaniline as described for methyl-2-nitroethylaniline above. The hydrochloride, from alcohol, had m. p. 123°. Yield, 90% (Found: C, 54.1; H, 6.7; N, 11.3. $C_{11}H_{16}O_2N_3.HCl$ requires C, 53.9; H, 6.9; N, 11.4%).

Ethyl-2-nitro-n-propylaniline.—This was prepared from 2-nitroprop-1-ene (58 g.) and ethylaniline (80 g.) in ether (250 c.c.) as described for the isomeride above. It was isolated as the hydrochloride, m. p. 126°, in 50% yield (Found: C, 54.1; H, 6.9; N, 11.3. $C_{11}H_{16}O_2N_3.HCl$ requires C, 53.9; H, 6.9; N, 11.4%).

2-Nitro-1-methyl-n-propylaniline.—2-Nitrobut-2-ene (24 g.) was added dropwise with stirring to aniline (18.6 g.) at 20°, the mixture maintained at 30° for 3 hours, and distilled, giving the base, b. p. 86°/0.5 mm., n_D^{20} 1.5570, in 72% yield. The hydrochloride, from methyl alcohol-ether, had m. p. 122° (Found: C, 52.4; H, 6.5; N, 12.0. $C_{10}H_{14}O_2N_3.HCl$ requires C, 52.1; H, 6.5; N, 12.1%). The perchlorate explodes on warming (Found: C, 41.1; H, 5.2; N, 9.4. $C_{10}H_{14}O_2N_3.HClO_4$ requires C, 40.7; H, 5.1; N, 9.5%).

The authors wish to acknowledge the advice and encouragement of Mr. C. Paine and Dr. H. A. Piggott.

[Received, January 23rd, 1947.]

287. Aliphatic Nitro-compounds. Part VIII. Addition of Primary and Secondary Nitro-paraffins to α -Nitro-olefins to give 1 : 3-Dinitro-paraffins.*

By A. LAMBERT and H. A. PIGGOTT.

Interaction of primary or secondary aliphatic nitro-compounds with α -nitro-olefins yields 1 : 3-dinitro-paraffins, which on reduction afford 1 : 3-diamines. The reaction appears to be a general one, but yields are variable. An attempted condensation of 2 : 4-dinitro-2 : 3-dimethylpentane with formaldehyde gave, surprisingly, methyl 2-nitro-1 : 2-dimethylpropyl ketoxime.

* Patent application pending.

MANY authors have described the addition of nitro-paraffins to activated ethylenic systems, including $\alpha\beta$ -unsaturated ketones (Kohler, *J. Amer. Chem. Soc.*, 1916, **38**, 889, and later papers), unsaturated esters (Kohler and Engelbrecht, *ibid.*, 1919, **41**, 764), and nitriles (Bruns, *ibid.*, 1943, **65**, 23), but little attention has been paid to their addition to the α -nitro-olefins. Worrall (*ibid.*, 1935, **57**, 2299; cf. Heim, *Ber.*, 1911, **44**, 2016) recorded the interaction of α -nitrostilbene and phenylnitromethane in the presence of ammonia to give 1:3-dinitro-1:2:3-triphenylpropane, and since the present work was completed, Hass (*Ind. Eng. Chem.*, 1943, **35**, 1151) has mentioned the formation of 1:3-dinitro-2:3-dimethylpropane from nitromethane and 1-nitro-2-methylpropene, but in neither case was experimental detail presented.

A systematic investigation of the addition of nitro-paraffins to nitro-olefins was undertaken as part of a general exploration of the addition reactions of the nitro-olefins and as a possible route to a wide variety of substituted 1:3-diamines of interest in connection with other work in these laboratories. The addition of a primary or secondary nitro-paraffin to a nitro-olefin, although a general reaction, afforded the 1:3-dinitro-paraffins in extremely variable yields.

Thus, 2-nitrobut-2-ene (I, $\text{R}' = \text{R}'' = \text{CH}_3$) and 2-nitropropane in presence of sodium ethoxide yielded 47% of 2:4-dinitro-2:3-dimethylpentane (II, $\text{R} = \text{R}' = \text{R}'' = \text{R}''' = \text{Me}$); in this case the nitro-olefin is not easily polymerised by alkali, the product, containing only one active hydrogen atom, does not easily interact further with unchanged nitro-olefin, and the amount of polymeric by-product was therefore negligible. In the presence of benzyltrimethylammonium hydroxide, nitroethane and 2-nitrobut-2-ene gave the dissecondary nitro-paraffin, 2:4-dinitro-3-methylpentane, in 28% yield with a considerable amount of by-product of high molecular weight which decomposed on attempted distillation; with sodium ethoxide or piperidine as catalyst the same product was obtained in lower yield. 2-Nitropropane and 2-nitroprop-1-ene gave (sodium ethoxide catalyst) 2:4-dinitro-2-methylpentane in 26% yield, and methyl 2-nitropropyl sulphide and methyl 2-nitropropyl ether (see Parts IV and III in this series) added (sodium methoxide catalyst) to 2-nitroprop-1-ene to give methyl 2:4-dinitro-2-methylamyl sulphide and methyl 2:4-dinitro-2-methylamyl ether, respectively; the latter was also obtained directly in 52% yield from two molecules of 2-nitroprop-1-ene and one of sodium methoxide without isolation of the intermediate methyl 2-nitropropyl ether. The higher nitro-olefins were less reactive; thus, 2-nitropropane and 1-nitrocyclohexene gave nitro-2-(1-nitroisopropyl)-cyclohexane in only 16% yield.

The properties of the 1:3-dinitro-paraffins are parallel to those of the simpler mononitro-compounds; they exhibit none of the instability associated with the 1:2-dinitro-paraffins. Hydrogenation in the presence of nickel catalysts affords 1:3-diamines; they dissolve in aqueous alkali and treatment of such solutions with bromine gives the α -bromo-derivatives which are useful for characterisation purposes. Surprising results were obtained in an attempt to cause 2:4-dinitro-2:3-dimethylpentane to interact with paraformaldehyde and sodium hydroxide; instead of the expected 4-hydroxymethyl derivative, methyl 2-nitro-1:2-dimethylpropyl ketoxime, m. p. 51° , was formed. This is the only known example of the reduction of a secondary nitro-paraffin by formaldehyde and alkali; the structure of the oxime was confirmed by reduction of the sodium salt of the dinitro-compound with stannous chloride and hydrochloric acid, a method specific for the reduction of primary or secondary nitro-paraffins to oximes (cf. Konowalov, *J. Russ. Phys. Chem. Soc.*, 1898, **30**, 960; *Chem. Zentr.*, 1899, I, 597). In addition to the oxime, m. p. 51° , above, the isomeride, m. p. $85-86^\circ$, was also formed, which was rearranged with phosphorus pentachloride to an isomeric amide.

The 2-nitroprop-1-ene used in this work was prepared by the method of Buckley and Scaife (this series, Part I).

EXPERIMENTAL.

Analyses are by Mr. E. S. Morton. M. ps. are uncorrected.

2:4-Dinitro-2:3-dimethylpentane.—A well-stirred solution of sodium ethoxide (39.6 g.) in alcohol (400 c.c.) was treated with 2-nitropropane (52.5 g.) at $15-20^\circ$, followed by 2-nitrobut-2-ene (59.5 g.; this series, Part III), and the whole refluxed. After cooling, the mixture was poured into iced water (1000 c.c.) and neutralised at 0° with 2*N*-hydrochloric acid. The solution was concentrated under reduced pressure and the residue extracted with ether. Distillation gave 2:4-dinitro-2:3-dimethylpentane (53 g.) as a pale yellow oil, b. p. $90-92^\circ/0.5$ mm. (Found: C, 44.9; H, 7.5; N, 14.5. $\text{C}_7\text{H}_{14}\text{O}_4\text{N}_2$ requires C, 44.2; H, 7.4; N, 14.7%). The 2-bromo-derivative, prepared from an aqueous solution of sodium 2:4-dinitro-2:3-dimethylpentane and the calculated quantity of bromine, formed colourless plates from methyl alcohol, m. p. 40° (Found: C, 30.8; H, 4.7; N, 10.3; Br, 29.7. $\text{C}_7\text{H}_{13}\text{O}_4\text{N}_2\text{Br}$

requires C, 31.2; H, 4.8; N, 10.4; Br, 29.7%). The 2-(*p*-nitrophenylazo)-derivative, prepared from sodium 2:4-dinitro-2:3-dimethylpentane and diazotised *p*-nitroaniline (cf. Feasley and Degering, *J. Org. Chem.*, 1943, 8, 12), formed orange prisms from alcohol, m. p. 142–143° (Found: C, 46.2; H, 5.1; N, 20.7. $C_{15}H_{11}O_5N_5$ requires C, 46.0; H, 5.0; N, 20.6%).

2:4-Diamino-2:3-dimethylpentane.—2:4-Dinitro-2:3-dimethylpentane (50 g.) in methyl alcohol was hydrogenated at 50–70° and 70 atm. (initial pressure) over Raney nickel. Fractionation of the product gave 2:4-diamino-2:3-dimethylpentane (17 g.) as a colourless liquid, b. p. 66–68°/30 mm., 180°/754 mm. Reduction with iron and hydrochloric acid gave the same diamine in poor yield. The NN'-dibenzoyl derivative formed colourless needles from benzene, m. p. 175° (Found: C, 74.5; H, 7.4; N, 8.2. $C_{21}H_{19}O_2N_4$ requires C, 74.6; H, 7.7; N, 8.3%). The *platinichloride* formed orange prisms from aqueous alcohol (Found: Pt, 36.1. $C_7H_{15}N_4H_3PtCl_6$ requires Pt, 36.1%).

Methyl 2-Nitro-1:2-dimethylpropyl Ketoxime.—(a) *By reduction with formaldehyde*. 2:4-Dinitro-2:3-dimethylpentane (10 g.), paraformaldehyde (1.6 g.), 40% aqueous sodium hydroxide (0.5 c.c.), and methyl alcohol (20 c.c.) were stirred at room temperature for 16 hours. After neutralisation with dilute hydrochloric acid, fractionation gave a colourless oil (8.2 g.), b. p. 90–91°/0.5 mm., which slowly deposited crystalline material. *Methyl 2-nitro-1:2-dimethylpropyl ketoxime* separated from light petroleum (b. p. 60–80°) as colourless plates, m. p. 51° (Found: C, 47.9; H, 8.1; N, 15.9. $C_7H_{11}O_3N_2$ requires C, 48.2; H, 8.0; N, 16.1%). The *p*-nitrophenylurethane formed fibrous needles from benzene–light petroleum (b. p. 60–80°), m. p. 109–110° (after being dried at 80° in a vacuum) (Found: C, 49.7; H, 5.2; N, 16.3. $C_{14}H_{15}O_3N_4$ requires C, 49.7; H, 5.3; N, 16.6%).

(b) *By reduction with stannous chloride*. A solution of 2:4-dinitro-2:3-dimethylpentane (30 g.) in aqueous sodium hydroxide (12.6%; 50 c.c.) was added dropwise with stirring to a solution of stannous chloride (35 g.) in concentrated hydrochloric acid (210 c.c.) at 0°. After being stirred for a further ½ hour at 0°, the solution was neutralised with sodium carbonate and extracted with ether. Distillation of the extract gave a viscous pale yellow oil (7 g.), b. p. 80–90°/0.1 mm., which crystallised on standing, m. p. and mixed m. p. with the oxime described above, 51°. The *p*-nitrophenylurethane had m. p. 109–110° alone or mixed with the specimen described above. The product from a second similar experiment was crystallised without distillation, giving an isomeric *oxime*, small needles from light petroleum (b. p. 60–80°), m. p. 85–86° (Found: C, 48.5; H, 8.1; N, 15.8. $C_7H_{11}O_3N_2$ requires C, 48.2; H, 8.0; N, 16.1%). With phosphorus pentachloride in dry ether the latter gave an isomeric *amide* which separated from benzene–light petroleum (b. p. 60–80°) in colourless needles, m. p. 83° (Found: C, 47.8; H, 8.2; N, 15.7. $C_7H_{11}O_2N_2$ requires C, 48.2; H, 8.0; N, 16.1%).

2:4-Dinitro-3-methylpentane.—2-Nitrobut-2-ene (50 g.) was added during 1 hour with stirring at ordinary temperature to a mixture of nitroethane (150 g.), dioxan (150 c.c.), and aqueous benzyltrimethylammonium hydroxide (40%; 6 c.c.). After being stirred for 48 hours at 40°, the mixture was diluted with water (500 c.c.) and neutralised with dilute hydrochloric acid. Extraction with ether, followed by fractionation, gave 2:4-dinitro-3-methylpentane (25 g.) as a pale yellow liquid, b. p. 94–95°/0.5 mm. (Found: N, 15.9. $C_8H_{13}O_4N_2$ requires N, 16.2%). The use of piperidine or sodium ethoxide as catalyst in this reaction gave a smaller yield of the same product. The 2:4-dibromo-derivative, prepared by the method described above from 2-bromo-2:4-dinitro-2:3-dimethylpentane, formed colourless prisms from aqueous methyl alcohol, m. p. 53–54° (Found: C, 21.7; H, 3.3; N, 8.0. $C_8H_{10}O_4N_2Br_2$ requires C, 21.6; H, 3.0; N, 8.3%).

2:4-Dinitro-2-methylpentane.—2-Nitropropane (21 g.) was added to 2-nitroprop-1-ene (20 g.; this series, Part I) as described above for the reaction of 2-nitropropane with 2-nitrobut-2-ene. 2:4-Dinitro-2-methylpentane (10.6 g.) was obtained as a pale yellow oil, b. p. 80°/0.2 mm. (Found: C, 41.3; H, 6.7. $C_8H_{13}O_4N_2$ requires C, 40.9; H, 6.8%). The 2-bromo-derivative formed colourless leaflets from aqueous methyl alcohol, m. p. 76° (Found: C, 27.7; H, 4.5; Br, 31.3. $C_8H_{11}O_4N_2Br$ requires C, 28.2; H, 4.3; Br, 31.4%).

2:4-Diamino-2-methylpentane.—2:4-Dinitro-2-methylpentane (9 g.) in methyl alcohol (100 c.c.) was hydrogenated at 70° and 75 atm. (initial pressure) over Raney nickel. The product was filtered, acidified with hydrochloric acid, evaporated to dryness, treated with excess of 50% aqueous potassium hydroxide, and extracted with ether. After drying over potassium hydroxide, distillation gave 2:4-diamino-2-methylpentane as a colourless liquid which fumed on exposure to air, b. p. 150–155°/756 mm. (Kohn, *Monatsh.*, 1902, 23, 6, gives b. p. 147–155°). The NN'-dibenzoyl derivative formed colourless prisms from aqueous methyl alcohol, m. p. 152° (Found: N, 8.6. $C_{20}H_{22}O_2N_4$ requires N, 8.6%).

Nitro-2-(1-nitroisopropyl)cyclohexane.—2-Nitropropane (8.9 g.) was brought into reaction with nitrocyclohexene (12.7 g.) (Wiand *et al.*, *Annalen*, 1921, 424, 71) as described above for the addition of 2-nitropropane to 2-nitrobut-2-ene. Fractionation of the product gave a pale yellow oil (3.5 g.), b. p. 95–110°/0.3 mm., which solidified on cooling, and recrystallised from light petroleum (b. p. 60–80°), giving *nitro-2-(1-nitroisopropyl)cyclohexane* in colourless plates, m. p. 103° (Found: C, 49.9; H, 7.3; N, 12.6. $C_9H_{15}O_3N_2$ requires C, 50.0; H, 7.4; N, 13.0%).

Methyl 2:4-Dinitro-2-methylamyl Ether.—(a) *From methyl 2-nitropropyl ether and 2-nitroprop-1-ene*. A well-stirred solution of sodium methoxide (4.1 g.) in methyl alcohol (50 c.c.) was treated with methyl 2-nitropropyl ether (9.1 g.; this series, Part III), followed by 2-nitroprop-1-ene (6.6 g.) at room temperature. After being stirred at 40–50° for ½ hour, the mixture was poured into iced water (100 c.c.) and neutralised with aqueous acetic acid. The alcohol was distilled under reduced pressure and the residue extracted with ether. Distillation of the ethereal solution gave *methyl 2:4-dinitro-2-methylamyl ether* (8.0 g.) as a pale yellow oil, b. p. 92–94°/0.1 mm. (Found: C, 41.2; H, 6.8; N, 13.1. $C_7H_{11}O_5N_2$ requires C, 40.8; H, 6.8; N, 13.6%). The 4-bromo-derivative formed colourless plates from aqueous methyl alcohol, m. p. 64° (Found: C, 29.6; H, 4.8; N, 9.5; Br, 27.9. $C_7H_{13}O_5N_2Br$ requires C, 29.5; H, 4.6; N, 9.8; Br, 28.1%).

(b) *From 2-nitroprop-1-ene and methyl alcohol*. 2-Nitroprop-1-ene (50 g.) was added dropwise with stirring to a solution of sodium methoxide (15.5 g.) in methyl alcohol (200 c.c.) at 0°. After being stirred at room temperature for ½ hour, the mixture was poured into ice-water (500 c.c.), neutralised with aqueous acetic acid, and extracted with ether. Distillation of the ethereal solution gave *methyl*

2: 4-dinitro-2-methylamyl ether (35 g.), b. p. 94–96°/0.2 mm. The 4-bromo-derivative had m. p. 64°, alone or mixed with the specimen described above.

Methyl 2: 4-Diamino-2-methylamyl Ether.—The dinitro-ether (above) (41.6 g.) in methyl alcohol (650 c.c.) was hydrogenated at 60–70° and 87 atm. (initial pressure). Fractionation of the product gave *methyl 2: 4-diamino-2-methylamyl ether* (20 g.) as a colourless liquid, b. p. 77–79°/10 mm. (Found: N, 18.7. $C_7H_{15}ON_4$ requires N, 19.2%). The *bis*-2: 4-dinitrophenylurea derivative (cf. McVeigh and Rose, J., 1945, 621) had m. p. 190° (Found: C, 44.7; H, 4.5; N, 19.8. $C_{21}H_{24}O_{11}N_8$ requires C, 44.6; H, 4.3; N, 19.9%).

Methyl 2: 4-Dinitro-2-methylamyl Sulphide.—Methyl 2-nitropropyl sulphide (19.6 g.; this series, Part IV) was brought into reaction with 2-nitroprop-1-ene (12.7 g.) as described above for the addition of 2-nitroprop-1-ene to methyl 2-nitropropyl ether. *Methyl 2: 4-dinitro-2-methylamyl sulphide* (10 g.) was obtained as a pale yellow oil, b. p. 110–115°/0.05 mm. (Found: N, 12.1; S, 14.3. $C_7H_{14}O_4N_4S$ requires N, 12.6; S, 14.4%).

288. Aliphatic Nitro-compounds. Part IX. Reaction of Nitro-paraffins with Ethylmagnesium Bromide.

By G. D. BUCKLEY.

In the reaction of nitroethane with ethylmagnesium bromide the first stage is addition of the Grignard reagent to the $N=O$ bond to form a complex (III) which on reduction with zinc and hydrochloric acid gives diethylamine. The complex may react with a second mol. of ethylmagnesium bromide with evolution of 1 mol. of ethane to form a new complex which yields *NN*-diethylhydroxylamine on hydrolysis. Nitromethane, 2-nitropropane, and 2-nitro-2-methylpropane form analogous complexes.

THE action of Grignard reagents on nitro-paraffins was first examined by Moureu (*Compt. rend.*, 1901, 132, 837), who observed that nitroethane reacted with 2 mols. of ethylmagnesium iodide to form *NN*-diethylhydroxylamine. He suggested that the reaction involved the direct addition of both mols. of Grignard reagent to the $N=O$ bonds, followed by breakdown on hydrolysis:

Bevad (*Ber.*, 1907, 40, 3065) studied the reactions of primary and secondary nitro-paraffins with several alkyl-zinc and -magnesium iodides. He found that nitroethane reacted with ethylmagnesium iodide with evolution of ethane and a little ethylene to give a complex which on hydrolysis gave *NN*-diethylhydroxylamine accompanied by smaller amounts of diethylamine and ethyl-*sec*-butylhydroxylamine. Ethylzinc iodide reacted in a similar manner, but gave ethyl-*sec*-butylhydroxylamine as the main product. Similar results were obtained with 1- and 2-nitropropanes. As the first stage in the reaction, Bevad postulated reaction of the Grignard reagent with the *aci*-form of the nitro-paraffin to give the complex (II), followed by addition of one or two mols. of Grignard reagent to the double bonds:

It was later shown by Zerewitinoff (*Ber.*, 1910, 43, 3593) that primary and secondary nitro-paraffins reacted with methylmagnesium iodide to give slightly less than 1 equivalent of methane, and he also considered that this arose from reaction with the *aci*-nitro-paraffin. Finally Wang (*Trans. Sci. Soc. China*, 1933, 7, 253) made a detailed study of the products obtained by the action of excess of phenylmagnesium bromide on nitromethane. The chief products were phenylmethylhydroxylamine, phenylbenzylhydroxylamine, phenol, and benzene, and a mechanism was formulated, differing in detail from Bevad's theory, but also based on the preliminary formation of a complex of type (II).

All the theories so far advanced are inadmissible since they involve quinquivalent nitrogen; a complex of type (I) as advocated by Moureu would be expected to yield a trialkylamine oxide and not a dialkylhydroxylamine on hydrolysis. The theories advanced by subsequent authors all postulate the preliminary tautomeric change of the nitro-compound to the *aci*-form, though no evidence has been adduced for the occurrence of this change, which normally requires strongly ionising conditions.

The reaction has therefore been re-examined, particular attention being directed to the initial stages. Treatment of nitroethane with 1 mol. of ethylmagnesium bromide at 0° resulted in a vigorous exothermic reaction to form a solid complex which separated from the solution. No gas was evolved during this reaction, but on addition of a further 2 mols. of Grignard reagent the complex largely redissolved and 1 mol. of gas was evolved; this reaction was relatively slow and required heating to drive it to completion. The gas was not identified, but was assumed to be mainly ethane on the evidence of Bevad (*loc. cit.*). The unreacted Grignard reagent, estimated by treating the mixture with water and collecting the evolved gas, amounted to 1 mol. The main liquid product was diethylhydroxylamine. The initial complex was shown by analysis to be an addition product of equimols. of nitroethane and ethylmagnesium bromide, and on reduction with zinc and hydrochloric acid it gave diethylamine in 60% yield. It must therefore have the structure (III). The analogous complex from nitromethane gave methylethylamine on reduction. Similar addition products were obtained by the action of ethylmagnesium bromide on 2-nitropropane and 2-nitro-2-methylpropane, but attempts to reduce them with zinc and hydrochloric acid failed owing to their instability.

It is evident from these results that the first step in the reaction of a nitro-paraffin with ethylmagnesium bromide is the addition of the Grignard reagent to the N=O bond to form a complex of type (III), which is then reduced by a second mol. of Grignard reagent, by a mechanism which is still obscure, to a product which on hydrolysis yields the dialkylhydroxylamine.

EXPERIMENTAL.

The nitro-paraffins used were purified by repeated distillation over phosphoric oxide, followed by thorough washing with water, drying (CaCl_2), and fractionation through a Widmer column. An ethereal solution of ethylmagnesium bromide was filtered through glass wool; the ethylmagnesium bromide content was determined by the method of Gilman *et al.* (*J. Amer. Chem. Soc.*, 1923, **45**, 150), and the solution was then diluted with dry ether to a concentration of 2 g.-mols. per l.

Nitroethane.—(a) A solution of nitroethane (7.5 g.) in pure dry ether (25 c.c.) was placed in a flask cooled in ice-salt and fitted with a mercury-sealed stirrer, reflux condenser, dropping funnel, and system for collecting evolved gases. Ethylmagnesium bromide solution (50 c.c.) was added dropwise to the stirred solution during 1 hour at -5° to 0° . A strongly exothermic reaction took place and a heavy white precipitate was formed, but no gas was evolved. A further 100 c.c. of the Grignard solution was added during 1 hour, by which time the precipitate had largely redissolved and 1400 c.c. of gas had been evolved. The mixture was then refluxed for 1 hour (resulting in the evolution of a further 800 c.c. of gas), cooled in ice, and treated with water (50 c.c.) dropwise at $0-10^\circ$. During the addition of the water, 2200 c.c. of gas were evolved.

(b) Ethylmagnesium bromide solution (50 c.c.) was added dropwise during 1 hour to a stirred solution of nitroethane (7.5 g.) in pure dry ether (100 c.c.) at -5° to 0° . The mixture was then refluxed for 1 hour; no gas was evolved. After cooling, the precipitate was collected, washed with pure dry ether, and dried in a vacuum at 20° , giving a hygroscopic white powder (17.4 g.) which appeared to decompose on treatment with water (Found: Br, 37.25; Mg, 11.65. $\text{C}_4\text{H}_{10}\text{O}_2\text{NBrMg}$ requires Br, 38.45; Mg, 11.64%).

This complex (15 g.) was dissolved in 19% hydrochloric acid (200 c.c.) with ice-cooling, and granulated zinc (30 g.) was added. The reduction was completed by heating on the steam-bath for a short time and the mixture was then cooled in ice, basified with excess of 32% sodium hydroxide solution, and steam-distilled into *n*-hydrochloric acid (100 c.c.); back-titration of the distillate with *n*-sodium hydroxide showed that base equivalent to 45.3 c.c. of *n*-acid (60% theory) had distilled. The neutralised solution was evaporated to dryness and the crude hydrochloride treated with concentrated sodium hydroxide solution. The base, which separated as a volatile oil, reacted with picryl chloride to give a picramide, m. p. $164-165^\circ$, not depressed on admixture with diethyl picramide, m. p. 165° (Found: N, 19.8. Calc. for $\text{C}_{10}\text{H}_{12}\text{O}_4\text{N}_4$: N, 19.7%). With phenyl isocyanate the base gave a urea, m. p. $83-84^\circ$, not depressed on admixture with *N*-phenyl-*NN*-diethylurea, m. p. 84° .

(c) Ethylmagnesium bromide solution (750 c.c.) was added during 2 hours to a stirred solution of nitroethane (37.5 g.) in dry ether (100 c.c.) at $0-10^\circ$. The mixture was refluxed for 4 hours, cooled, poured into ice, and steam-distilled until the distillate was only faintly alkaline to brilliant-yellow paper. The distillate was acidified with hydrochloric acid, and the ethereal layer was separated, washed with water, and discarded. The combined aqueous layer and washings were concentrated under reduced pressure, cooled, treated with a large excess of sodium hydroxide, and extracted with ether. The extract was dried (KOH) and fractionated to give diethylhydroxylamine as a colourless oil (20.4 g.), b. p. $50-52^\circ/18$ mm. (Found: equiv., 88.3. Calc. for $\text{C}_4\text{H}_{11}\text{ON}$: equiv., 89), together with small amounts of a volatile base, probably diethylamine, and a high-boiling residue which was not further examined.

Nitromethane.—Nitromethane (6.1 g.) was brought into reaction with ethylmagnesium bromide solution (50 c.c.) by the method (b) described above for nitroethane. This gave the complex (14.5 g.) as a hygroscopic white powder (Found: Br, 41.75; Mg, 12.65. $\text{C}_3\text{H}_5\text{O}_2\text{NBrMg}$ requires Br, 41.25; Mg, 12.4%). Reduction with zinc and hydrochloric acid gave methylethylamine (63% yield), characterised as the picrate, m. p. 96° , and the hydrobromide, m. p. $87-88^\circ$ (Found: Br, 57.2. Calc. for $\text{C}_3\text{H}_7\text{N.HBr}$: Br, 57.15%).

2-Nitropropane.—2-Nitropropane (8.9 g.) was brought into reaction with ethylmagnesium bromide solution (50 c.c.) by the method (b) described above for nitroethane to give the complex (17.2 g.) as a

hygroscopic white powder (Found: Br, 35.3; Mg, 10.65. $C_6H_{11}O_2NBrMg$ requires Br, 36.05; Mg, 10.8%).

Nitro-tert.-butane.—Nitro-*tert.*-butane (10.3 g.) was brought into reaction with ethylmagnesium bromide solution (50 c.c.) by the method (b) described above for nitroethane. This gave a hygroscopic white complex (10 g.) (Found: Br, 34.2; Mg, 10.3. $C_6H_{14}O_2NBrMg$ requires Br, 33.9; Mg, 10.15%).

The author wishes to thank Dr. H. A. Piggott and Mr. J. D. Rose for advice and encouragement during this work.

289. Aliphatic Nitro-compounds. Part X. Action of Grignard Reagents on the α -Nitro-olefins.

By G. D. BUCKLEY.

The reactions of ethyl- and butyl-magnesium bromides with two primary and one secondary α -nitro-olefins have been studied, and, although most of the reaction products have been identified, several points in the mechanism remain obscure. The initial step is a rapid 1:4-addition of the Grignard reagent to the conjugated system $C:C:N=O$ to give a complex which may be decomposed by water to give a nitro-paraffin, or may react with more Grignard reagent to give another complex which on treatment with water yields an oxime. Simultaneously, some 1:2-addition to the nitro-olefin occurs, to give a complex which with water gives basic products, probably dialkylhydroxylamines.

ALTHOUGH organo-magnesium halides readily add to the $N=O$ bond of the nitro-group (see Part IX of this series), Kohler and Stone (*J. Amer. Chem. Soc.*, 1930, 52, 761) have shown that α -nitrostilbene and triphenylnitroethylene react with organo-magnesium halides to give exclusively 1:4-addition products. It was therefore of interest to study the reaction of Grignard compounds with aliphatic nitro-olefins to find whether 1:2-addition (Type A) or 1:4-addition (Type B) predominated.

Addition of ethylmagnesium bromide to an ethereal solution of nitroethylene resulted in immediate polymerisation of the nitro-olefin, but, by reversing the procedure, polymerisation was completely prevented. Slow addition of nitroethylene to 3 mols. of ethylmagnesium bromide at 10–15° resulted in a slow evolution of gas, which was accelerated on boiling the mixture. When 0.66 mol. of gas had been evolved, reaction appeared to be complete, and on treatment of the mixture with water a further 0.75 mol. of gas was evolved, presumably from unreacted Grignard reagent. The acid-insoluble part of the product consisted essentially of two substances, (a) 1-nitrobutane (20% yield) identified by its nitrolic acid reaction (Meyer, *Annalen*, 1875, 175, 120) and by its degradation to *n*-butaldehyde, and (b) hexan-3-one oxime (30% yield) which was readily converted into the corresponding 2:4-dinitrophenylhydrazone (Allen, *J. Amer. Chem. Soc.*, 1930, 52, 2995) and was also reduced to 3-aminohexane. The acid-soluble part of the product was small and boiled over a wide range. It reduced ammoniacal silver nitrate and was hydrogenated to a mixture of non-reducing bases, but no identifiable substance was isolated either before or after hydrogenation. These properties indicated presence of a hydroxylamine.

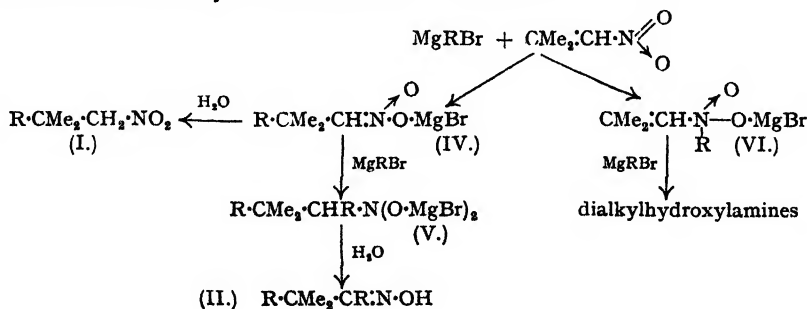

Nitroethylene reacted similarly with excess of *n*-butylmagnesium bromide to give a 43% yield of 1-nitrohexane, a 27.5% yield of a neutral oil, $C_{10}H_{21}ON$, and a small amount of reducing bases. The compound, $C_{10}H_{21}ON$, was assumed to be *decan-5-one oxime* from its reactions and by analogy with the previous example. It was converted into an oily 2:4-dinitrophenylhydrazone which, in agreement with the failure of Bried and Hennion (*J. Amer. Chem. Soc.*, 1938, 60, 1718) to prepare crystalline derivatives of decan-5-one, could not be obtained solid; catalytic reduction gave 5-aminodecane.

Since 1-nitro-2-methylprop-1-ene is not polymerised by Grignard reagents, it was possible to

study more closely the course of the reaction of ethylmagnesium bromide with this nitro-olefin. This reaction of the first mol. of Grignard reagent was strongly exothermic and took place readily at 0° without evolution of gas. Further Grignard reagent reacted only slowly at 0°, but more readily at 15–20°. The reaction was mildly exothermic, and 1 mol. of gas was evolved, 3 mols. of Grignard reagent being consumed in all. The gas had the properties of a saturated hydrocarbon, and on combustion was found to be chiefly ethane. The products were 1-nitro-2:2-dimethylbutane (20%) (which gave the characteristic primary nitro-compound reaction and on reduction afforded the known 1-amino-2:2-dimethylbutane), and a crystalline solid, $C_8H_{13}ON$ (28%), which failed to react with 2:4-dinitrophenylhydrazine or 2:4-dinitrophenylsemicarbazide and was hydrogenated only with difficulty to a primary amine, $C_8H_{15}N$; by analogy with the previous examples it is believed to be 3:3-dimethylhexan-4-one oxime (II; $R = Et$), and the derived amine, 4-amino-3:3-dimethylhexane, the unreactivity of the oxime being attributed to steric factors.

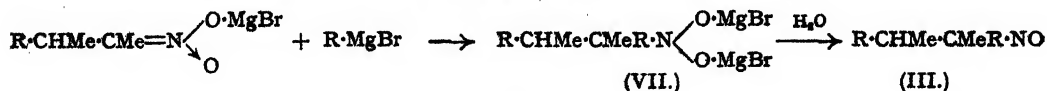

Addition of ethylmagnesium bromide to 2-nitrobut-2-ene gave polymers as in the case of nitroethylene, but this was again overcome by adding the nitro-olefin to excess of the Grignard reagent. Gaseous hydrocarbon (0.75 mol.) was evolved and 2.5 mols. of ethylmagnesium bromide were consumed. An acid-soluble fraction consisting of reducing bases similar to those obtained from the primary nitro-olefin was isolated, and the neutral fraction was separated into an oil, $C_6H_{13}O_2N$ (26%), an oil, $C_8H_{17}ON$ (8%), and a large amount of non-volatile tar. The compound $C_8H_{13}O_2N$, which gave the nitrole reaction characteristic of a secondary nitro-group (Meyer, *loc. cit.*) and yielded a primary amine on reduction, was 2-nitro-3-methylpentane. The oil, $C_8H_{17}ON$, was colourless and contained one active hydrogen atom (Zerewitinoff); this excluded the possibility that it had the nitroso-structure (III; $R = Et$). It did not give the Meyer test for a nitro-paraffin, but on reduction it gave an amine, $C_8H_{19}N$. It must therefore be an oxime although, like the isomeric 3:3-dimethylhexan-4-one oxime, it failed to react with 2:4-dinitrophenylhydrazine or 2:4-dinitrophenylsemicarbazide.

On the basis of these results it is possible to build up a fairly complete picture of the course of the reaction of a Grignard reagent with a primary nitro-olefin, as shown in the scheme below for the reaction of ethylmagnesium bromide with 1-nitro-2-methylpropene. The initial step is addition (chiefly 1:4) of the Grignard reagent to the conjugated system to produce a complex (IV) which on hydrolysis gives the nitro-paraffin (I), but since (IV) contains the system $C=N \rightarrow O$, addition of a second mol. of Grignard reagent occurs to give the complex (V) which on hydrolysis yields the oxime (II). The formation of reducing bases and of ethane can be explained only by the assumption that part of the nitro-olefin undergoes 1:2-addition of Grignard reagent to give a complex (VI) which reacts with more Grignard reagent to give dialkylhydroxylamines; this process is analogous to the formation of dialkylhydroxylamines by the action of Grignard reagents on nitro-paraffins (this series, Part IX; Bevad, *Ber.*, 1907, 40, 3065). Unfortunately, the nitro-olefin reaction produces mixtures of bases of so complex a nature and in such small amount that it has not been possible to isolate pure products which would establish with certainty the occurrence of 1:2-addition.

The secondary nitro-olefin underwent a similar series of reactions. The formation of 2-nitro-3-methylpentane in the reaction of 2-nitrobut-2-ene with ethylmagnesium bromide is clear evidence of 1:4-addition, and the isolation of reducing bases and the formation of a hydrocarbon again point to the occurrence of some 1:2-addition. The nature of the reaction of the 1:4-addition complex of the secondary nitro-olefin with more Grignard reagent is obscure; if it followed the same course as for the primary nitro-olefins the product would be a nitroso-compound (III). However, as stated above, although a product of the same empirical

formula as (III) was isolated, it appeared to be an oxime, which may result from a rearrangement of (II) or of its complex (VII). Such a rearrangement might also explain the extensive tar formation, which was observed only in the case of the secondary nitro-olefin.

EXPERIMENTAL.

Microanalyses are by Mr. E. S. Morton. All m. ps. are uncorrected.

Nitroethylene and Ethylmagnesium Bromide.—A solution of nitroethylene (Levy, Scaife, and Wilder-Smith, *J.*, 1946, 1096) (11.2 g.) in dry ether (60 c.c.) was added during 1 hour to a stirred solution of ethylmagnesium bromide (from 50 g. ethyl bromide) in ether (250 c.c.) at 10–15°, and the mixture was then stirred and refluxed for 2 hours; gas evolution had then ceased. This gas (2100 c.c. at N.T.P.) did not react with bromine and did not liquefy on cooling to –80°. The mixture was cooled in ice, and water (100 c.c.) was added dropwise; a further 2300 c.c. of gas were evolved. The mixture was acidified to Congo-red with dilute sulphuric acid, separated, and the aqueous layer, made strongly alkaline with sodium hydroxide, was extracted with ether in a continuous extractor. The extract was dried (NaOH) and distilled, giving a strongly basic oil (4.8 g.) which boiled over a wide range under reduced pressure and reduced ammoniacal silver nitrate. Catalytic hydrogenation in the presence of Raney nickel gave a non-reducing basic oil which distilled over a wide range and from which no crystalline derivative could be prepared.

The ethereal solution containing the acid-insoluble products was dried and distilled. Two fractions were isolated: (1) b. p. 50–65°/30 mm., and (2) b. p. 90–100°/30 mm. Redistillation of fraction (1) gave 1-nitrobutane (3.2 g.) as a colourless oil, b. p. 150–152°, which gave a positive test for the presence of a primary nitro-group (Meyer, *loc. cit.*). A solution of the nitro-compound in dilute aqueous sodium hydroxide, run into excess of 20% sulphuric acid at 10–15°, gave *n*-butaldehyde (2:4-dinitrophenylhydrazones, m. p. and mixed m. p. with an authentic specimen, 126°).

Redistillation of fraction (2) gave hexan-3-one oxime (4.7 g.) as a colourless oil, b. p. 98–100°/30 mm. (Found: N, 12.0. Calc. for $\text{C}_6\text{H}_{13}\text{ON}$: N, 12.2%). The oxime, with 2:4-dinitrophenylhydrazine in 2*N*-hydrochloric acid, gave hexan-3-one 2:4-dinitrophenylhydrazone as red needles, m. p. 128–129°; Allen (*loc. cit.*) gives m. p. 129° (Found: C, 50.95; H, 5.5; N, 20.4. Calc. for $\text{C}_{12}\text{H}_{14}\text{O}_4\text{N}_4$: C, 51.4; H, 5.7; N, 20.0%).

3-Aminohexane. A solution of hexan-3-one oxime (3.5 g.) in methyl alcohol (35 c.c.) was shaken with Raney nickel and hydrogen at 20°/1 atm. until absorption ceased. The filtered solution was acidified with hydrochloric acid and evaporated to dryness, and the residue after being washed with acetone afforded 3-aminohexane hydrochloride, m. p. 225–226°. Bevad (*J. pr. Chem.*, 1901, 63, 230) gives m. p. 227–229° (Found: Cl, 25.2. Calc. for $\text{C}_6\text{H}_{13}\text{N.HCl}$: Cl, 25.9%). The hydrochloride with potassium cyanate in boiling aqueous solution gave 3-ureidohexane, m. p. 150–151° (Found: C, 58.65; H, 11.3; N, 18.9. $\text{C}_6\text{H}_{13}\text{ON}_2$ requires C, 58.35; H, 11.1; N, 19.35%).

Nitroethylene and *n*-Butylmagnesium Bromide.—Nitroethylene (14.6 g.) was brought into reaction with a Grignard solution, prepared from *n*-butyl bromide (75.5 g.), as described above for ethylmagnesium bromide. When reaction was complete the mixture was cooled in ice, decomposed by cautious addition of aqueous acetic acid (150 c.c. of 20%), and separated. The ethereal solution was washed with dilute sodium hydrogen carbonate solution, dried, and distilled. This gave two fractions: (1) b. p. 84°/21 mm., and (2) b. p. 120–123°/12 mm. Fraction (1), a colourless, sweet-smelling oil which gave the nitrolic acid reaction, was 1-nitrohexane (Found: C, 55.15; H, 9.85; N, 10.65. Calc. for $\text{C}_6\text{H}_{13}\text{O}_2\text{N}$: C, 54.95; H, 9.9; N, 10.7%). Hydrolysis with concentrated hydrochloric acid at 160° in a sealed tube for 12 hours gave hexoic acid, which was characterised as the amide, m. p. 98°, and the anilide, m. p. 95°. Fraction (2) was a colourless oil, decan-5-one oxime (Found: C, 70.5; H, 12.45; N, 7.95. $\text{C}_{10}\text{H}_{21}\text{ON}$ requires C, 70.2; H, 12.3; N, 8.2%).

***n*-Hexylamine.** A solution of 1-nitrohexane (5.5 g.) in methyl alcohol (80 c.c.) was shaken with Raney nickel and hydrogen at 20°/1 atm. until absorption ceased. The filtered solution was acidified with hydrochloric acid and evaporated to dryness, giving the hydrochloride (2.25 g.) which, after being washed with acetone, had m. p. 217–218° (Found: Cl, 25.75. Calc. for $\text{C}_6\text{H}_{13}\text{N.HCl}$: Cl, 25.9%). With potassium cyanate in boiling aqueous solution the hydrochloride gave *n*-hexylurea, m. p. 108° (cf. Norstedt and Wahlforss, *Ber.*, 1892, 25, ref. 637).

5-Aminodecane. 5-Decanone oxime (3 g.) was dissolved in methyl alcohol and hydrogenated over Raney nickel at 20°/1 atm. After filtration and evaporation, 5-aminodecane was obtained as an oil which on treatment with phenyl isocyanate gave 5-phenylureidodecane, m. p. 129–130°, colourless needles from acetic acid (Found: C, 73.85; H, 10.1; N, 10.15. $\text{C}_{11}\text{H}_{23}\text{ON}_2$ requires C, 73.9; H, 10.15; N, 10.15%).

1-Nitro-2-methylprop-1-ene and Ethylmagnesium Bromide.—1-Nitro-2-methylprop-1-ene (25 g.; Levy and Scaife, in the press) was dissolved in dry ether (25 c.c.) and cooled to 0°. A solution of ethylmagnesium bromide (125 c.c.) was added during 1 hour with stirring at 0–5°; no gas was evolved. The temperature was raised to 15° and a further 475 c.c. of the Grignard solution were added during 1 hour at 15–25°; 5.5 l. of ethane were evolved. The mixture was refluxed for 12 hours, cooled and treated dropwise with water (125 c.c.) which liberated a further 5.5 l. of ethane. After acidification with dilute hydrochloric acid, the mixture was separated and the aqueous portion was made strongly alkaline with sodium hydroxide and steam-distilled. From the distillate was obtained by isolation with ether a small amount of a strongly basic oil which reduced ammoniacal silver nitrate.

The ethereal solution, containing the acid-insoluble products, was dried and distilled, giving two

fractions. Fraction (1) (6.2 g.), a colourless, sweet-smelling oil, b. p. 70°/25 mm., which gave the nitrolic acid reaction, was 1-nitro-2:2-dimethylbutane (I; R = Et) (Found: C, 54.75; H, 9.8; N, 10.8. $C_8H_{15}O_2N$ requires C, 54.95; H, 9.9; N, 10.7%). Fraction (2) (10.1 g.), a colourless crystalline solid, b. p. 100°/25 mm., was 3:3-dimethylhexan-4-one oxime (II; R = Et), m. p. 42–43°, from light petroleum (b. p. 40–60°) (Found: C, 67.55; H, 12.1; N, 9.65. $C_{12}H_{21}ON$ requires C, 67.15; H, 11.9; N, 9.8%).

1-Amino-2:2-dimethylbutane. A solution of the nitro-compound (4.3 g.) in methyl alcohol (50 c.c.) was shaken with Raney nickel and hydrogen at 20°/1 atm. until absorption ceased. The filtered solution was fractionally distilled, giving the amine as a colourless oil (2.3 g.), b. p. 110–115° (Found: equiv., 99.9. Calc. for $C_8H_{17}N$: equiv. 101). The picramide, yellow needles from alcohol, had m. p. 80° (Found: C, 46.25; H, 5.25; N, 17.85. Calc. for $C_{12}H_{19}O_6N_4$: C, 46.15; H, 5.1; N, 18.0%). The benzenesulphonyl derivative had m. p. 59° (Found: N, 6.05. Calc. for $C_{13}H_{19}O_2NS$: N, 5.8%). Drake, Kline, and Rose (*J. Amer. Chem. Soc.*, 1934, 56, 2079) give m. p. 88–88.5° for the picramide and m. p. 59–59.5° for the benzenesulphonyl derivative of 1-amino-2:2-dimethylbutane.

4-Amino-3:3-dimethylhexane. A solution of 3:3-dimethylhexan-4-one oxime (6.8 g.) in methyl alcohol (70 c.c.) was stirred in an autoclave with Raney nickel and hydrogen at 100°/100 atm. until absorption ceased. The filtered solution was acidified with hydrochloric acid and evaporated to dryness. The product was dissolved in a little water, washed with ether, basified with sodium hydroxide, extracted with ether, and the extract dried (KOH). Distillation gave 4-amino-3:3-dimethylhexane (3.3 g.) as a colourless oil, b. p. 152° (Found: equiv., 130.7. $C_8H_{19}N$ requires equiv., 129). Reaction with phenyl isocyanate in dry ether gave 4-phenylureido-3:3-dimethylhexane, m. p. 157–158°, colourless needles from acetic acid (Found: C, 72.45; H, 9.65; N, 11.35. $C_{15}H_{24}ON_2$ requires C, 72.6; H, 9.7; N, 11.3%). With picryl chloride in alcohol the base gave 4-picrylamino-3:3-dimethylhexane, m. p. 60°, orange plates from alcohol (Found: C, 49.6; H, 5.5; N, 16.65. $C_{14}H_{20}O_6N_4$ requires C, 49.4; H, 5.9; N, 16.45%).

2-Nitrobut-2-ene and Ethylmagnesium Bromide.—2-Nitrobut-2-ene (62 g.; this series, Part III) was brought into reaction, under the conditions described above for nitroethylene, with a Grignard solution prepared from ethyl bromide (218 g.); 10 l. of ethane were evolved. Distillation of the acid-insoluble portion of the product under reduced pressure left a large non-volatile tarry residue, and repeated fractionation separated the distillate into two fractions. The acid-soluble portion (12 g.), fraction (3), was isolated by treatment of the aqueous solution with sodium hydroxide, followed by extraction with ether in a continuous extractor. Fraction (1) (20.3 g.), a colourless oil, b. p. 68–70°/25 mm., which gave the μ -nitrolic acid reaction (Meyer, *loc. cit.*), was 2-nitro-3-methylpentane (Found: C, 54.75; H, 9.6; N, 10.8. $C_8H_{15}O_2N$ requires C, 54.95; H, 9.9; N, 10.7%). Fraction (2) (7 g.) was a colourless oil, b. p. 98–100°/20 mm., which did not give the Meyer nitro-paraffin test and did not react with 2:4-dinitrophenylhydrazine in acid solution (Found: C, 67.8; H, 11.8; N, 10.1; active H (Zerewitinoff) 0.63. $C_8H_{15}ON$ requires C, 67.15; H, 11.9; N, 9.8; 1 active H, 0.7%). On reduction with Raney nickel and hydrogen in methyl alcohol at 100°/100 atm. fraction (2) gave a colourless basic oil, b. p. 157–158° (Found: equiv., 130.2. $C_8H_{19}N$ requires equiv., 129), which gave a hydrochloride of indefinite m. p., readily soluble in alcohol, acetone, and ether (Found: Cl, 21.65. $C_8H_{19}N.HCl$ requires Cl, 21.45%).

Fraction (3) was a strongly basic oil, boiling over a wide range (40–110°/10 mm.); it reduced ammoniacal silver nitrate and absorbed hydrogen in the presence of a nickel catalyst, but no crystalline derivatives could be obtained from the resulting mixture of amines.

2-Amino-3-methylpentane. A solution of 2-nitro-3-methylpentane (10 g.) in methyl alcohol (100 c.c.) was shaken with Raney nickel and hydrogen at 20°/1 atm. until absorption ceased. The filtered solution was distilled, giving 2-amino-3-methylpentane as a colourless oil, b. p. 105–107° (Found: equiv., 102.7. $C_8H_{15}N$ requires equiv., 101). With picryl chloride it gave a picramide, m. p. 58–59° (Found: C, 46.3; H, 5.1; N, 17.7. $C_{13}H_{19}O_6N_4$ requires C, 46.15; H, 5.1; N, 18.0%).

The author wishes to acknowledge the interest and advice of Dr. H. A. Piggott and Mr. J. D. Rose in this work.

290. Aliphatic Nitro-compounds. Part XI. Preparation of Nitro-paraffins by 1:4-Addition of Organometallic Halides to α -Nitro-olefins.*

By GERARD D. BUCKLEY and ERIC ELLERY.

A series of hitherto unknown or inaccessible nitro-paraffins has been prepared by 1:4-addition of alkyl- or aryl-magnesium halides or alkylzinc halides to α -nitro-olefins. By carrying out the reaction below 10° and avoiding excess of organometallic halide secondary reactions are almost completely suppressed, but the yield of nitro-paraffin never exceeds 65% and is frequently less, apparently owing to the simultaneous occurrence of some 1:2-addition.

THE formation of nitro-paraffin derivatives in high yield by the action of Grignard reagents on di- and tri-phenylnitroethylenes has been described by Kohler and Stone (*J. Amer. Chem. Soc.*, 1930, 52, 761). Under similar conditions simpler nitro-olefins yield a complex mixture of

* Cf. B.P. 571,804.

products of which the nitro-paraffin forms only a small proportion (Part X of this series). The nitro-paraffins are formed by 1 : 4-addition of the Grignard reagent to the conjugated system and the by-products arise partly from 1 : 2-addition and partly from the action of excess of Grignard reagent on the initial addition products.

The results described in Part X indicate that the initial addition occurs much more readily than the subsequent reactions, and it has now been found that, by working at low temperatures and avoiding excess of Grignard reagent, secondary reactions are suppressed, and nitro-paraffins are obtained as the main products. The reaction has been carried out on a variety of nitro-olefins and organomagnesium halides (and one alkylzinc halide) and appears to be quite general. The yields are frequently poor, but are probably capable of considerable improvement, since 60–65% yields were obtained consistently in the only two examples in which any attempt was made to determine the optimum conditions of reaction and isolation, *viz.*, the reaction of *n*-butylmagnesium bromide with nitroethylene and of ethylmagnesium bromide with 1-nitro-2-methylprop-1-ene.

In the two cases in which alkylmagnesium iodides were used small amounts of crystalline by-products were formed, but owing to the smallness of the amounts available they were not further investigated; no trace of these compounds was found when the corresponding bromides were used.

EXPERIMENTAL.

Microanalyses are by Mr. E. S. Morton. All m. ps. are uncorrected.

1-Nitro-2 : 2-dimethylbutane.—(a) *From ethylmagnesium bromide.* A solution of ethylmagnesium bromide, prepared from ethyl bromide (48 g.) in ether (200 c.c.), was added during 1 hour to a stirred solution of 1-nitro-2-methylprop-1-ene (40 g.; Levy and Scaife, in the press) in pure, dry ether (400 c.c.), the temperature being held at 0–10°. The mixture was refluxed for 1 hour, cooled in ice, and treated cautiously with a solution of acetic acid (20 c.c.) in water (160 c.c.). The ethereal layer was washed with dilute sodium carbonate solution, dried, and distilled, giving 1-nitro-2 : 2-dimethylbutane (30.2 g.; 60% of theory) as a sweet-smelling oil, b. p. 168–170° (cf. Part X).

(b) *From ethylmagnesium iodide.* To an ice-cold, stirred solution of ethylmagnesium iodide, prepared in the usual manner from ethyl iodide (78 g.) in ether (200 c.c.), was added 1-nitro-2-methylprop-1-ene (34 g.) in ether (40 c.c.) during 1 hour at 0–10°. The mixture was stirred at 20° for 2 hours and worked up as before. Distillation of the crude product gave 25.3 g. (57.5% theory) of 1-nitro-2 : 2-dimethylbutane, b. p. 168–170°. The undistilled residue was crystallised from alcohol, giving colourless granules (0.4 g.) of an unidentified product, m. p. 182° (Found : C, 52.25; H, 7.55; N, 14.75. $C_8H_{14}O_2N_2$ requires C, 51.6; H, 7.5; N, 15.05%).

(c) *From ethylzinc iodide.* A solution of ethylzinc iodide in dry toluene, prepared from ethyl iodide (47 g.), was stirred at 0–10° and treated with a solution of 1-nitro-2-methylprop-1-ene (15 g.) in pure, dry ether (15 c.c.) during 1 hour. The mixture was then stirred at 50° for 3 hours, poured into ice, and treated with glacial acetic acid (20 c.c.). The organic layer was separated, dried, and fractionated to give 1-nitro-2 : 2-dimethylbutane (5.6 g.), b. p. 78–80°/30 mm.

Nitro-norbornane.—A solution of methylmagnesium iodide, prepared from methyl iodide (71 g.), was brought into reaction with 1-nitro-2-methylprop-1-ene (34 g.) as described above for ethylmagnesium iodide. After working up in the usual manner, the crude product was distilled, giving *nitro-norbornane* (16.2 g.; 42%) as a colourless oil, b. p. 77–78°/65 mm. (Found : C, 51.65; H, 9.35; N, 11.95. $C_8H_{11}O_2N$ requires C, 51.3; H, 9.4; N, 11.95%). The non-volatile residue crystallised on cooling and was purified by recrystallisation from alcohol and benzene, giving colourless prisms, m. p. 144° (Found : C, 46.8; H, 7.8; N, 13.05. $C_8H_{10}O_2N$ requires C, 47.05; H, 7.85; N, 13.7%).

1-Nitro-2 : 2 : 3 : 3-tetramethylpentane.—A solution of *tert*-amylmagnesium chloride, prepared from *tert*-amyl chloride (21.3 g.) by the method of Whitmore and Badertscher (*J. Amer. Chem. Soc.*, 1933, **55**, 1559), was brought into reaction with 1-nitro-2-methylprop-1-ene (10 g.) as described above for ethylmagnesium iodide. After isolation as before, the crude product was fractionated to give a colourless oil (6.5 g.), b. p. 102–105°/11 mm., having a camphor-like odour (Found : C, 62.55; H, 10.65; N, 8.45. $C_{12}H_{21}O_2N$ requires C, 62.45; H, 10.95; N, 8.1%).

$\alpha\alpha\beta\beta$ -Tetramethylvaleric Acid.—1-Nitro-2 : 2 : 3 : 3-tetramethylpentane (6 g.) was mixed with concentrated aqueous hydrochloric acid (20 c.c.) and heated in a sealed tube at 150° for 6 hours. The product was diluted with water and extracted with ether, and the ethereal solution washed thoroughly with dilute aqueous sodium carbonate. The alkaline extract was acidified with dilute sulphuric acid, extracted with ether, and the dried ethereal solution was distilled, giving $\alpha\alpha\beta\beta$ -tetramethylvaleric acid, b. p. 122°/15 mm., m. p. 89–90° [from light petroleum (b. p. 40–60°)] (Found : C, 68.8; H, 11.4; equiv., 158. $C_8H_{15}O_4$ requires C, 68.35; H, 11.4%; equiv., 158).

1-Nitro-2 : 2-dimethylpent-4-ene.—Allyl bromide (41 g.) in dry ether (250 c.c.) was converted into the Grignard reagent by the method of Gilman and McGlumphy (*Bull. Soc. chim.*, 1928, **43**, 1322), and the resulting solution filtered through glass wool and cooled to 0°. A solution of 1-nitro-2-methylprop-1-ene (20 g.) in dry ether (50 c.c.) was then added with stirring during 1 hour at 0–10°. After being stirred at 20° for 2 hours the mixture was poured into ice, treated with acetic acid (25 c.c.), and separated. The ethereal solution was dried and distilled under reduced pressure, giving much unchanged 1-nitro-2-methylprop-1-ene and a small yield (6.5 g.) of 1-nitro-2 : 2-dimethylpent-4-ene, b. p. 77°/20 mm. (Found : N, 9.7. $C_7H_{13}O_2N$ requires N, 9.8%). This was a pleasant-smelling oil, which gave the Meyer test for a primary nitro-compound, and reacted with bromine in carbon tetrachloride to give a liquid bromo-derivative.

1-Nitrohexane.—Nitroethylene (21 g.) dissolved in dry ether (100 c.c.) was added during 1 hour to a stirred solution of *n*-butylmagnesium bromide (0.4 g. mol.) in ether (250 c.c.). A vigorous exothermic reaction ensued, and the temperature was maintained below 0° with a freezing mixture; when the addition was complete the mixture was stirred for 1 hour at 20° and the complex decomposed by cautious addition of a solution of acetic acid (48 c.c.) in water (240 c.c.). After being stirred for a further 45 minutes, the mixture was steam-distilled, the ethereal layer of distillate separated, dried, and distilled, giving 38.6 g. (65%) of 1-nitrohexane, b. p. 84°/21 mm.; n_D^{20} 1.4270 (cf. Part X of this series) (Found : N, 10.65. Calc. for $C_6H_{13}O_2N$: N, 10.7%).

2-Nitro-3-methylpentane.—2-Nitrobut-2-ene (50 g.; this series, Part III) was dissolved in dry ether (250 c.c.) and brought into reaction with a solution of ethylmagnesium bromide (0.75 g. mol.) in ether (375 c.c.) as described above for the preparation of 1-nitrohexane. After working up in the usual way 2-nitro-3-methylpentane (27.7 g.; 42.5%) was obtained as a colourless oil, b. p. 70–73°/20 mm.; n_D^{20} 1.4320 (cf. Part X of this series) (Found : N, 10.8. Calc. for $C_6H_{13}O_2N$: N, 10.7%).

2-Nitropentane.—2-Nitroprop-1-ene (17.4 g.; this series, Part I) dissolved in dry ether (60 c.c.) was brought into reaction with ethylmagnesium bromide (from 22 g. of ethyl bromide) in ether (100 c.c.) as described above for the preparation of 1-nitrohexane. After working up in the usual way the crude distillate (b. p. 40–60°/12 mm.) was washed with aqueous sodium hydrogen sulphite to remove unchanged 2-nitroprop-1-ene, dried, and fractionated, giving a colourless oil, b. p. 148–150°. 2-Nitropentane is a pleasant-smelling oil, soluble in dilute aqueous sodium hydroxide, which gives the Meyer test for a secondary nitro-compound (Found : C, 51.65; H, 9.7; N, 11.8. $C_5H_{11}O_2N$ requires C, 51.3; H, 9.4; N, 11.95%). Reduction of 2-nitropentane (3.5 g.) in methyl alcohol with hydrogen in the presence of Raney nickel in the usual way gave 2-aminopentane, isolated as the hydrochloride (3.4 g.). Reaction of the base with phenyl isocyanate gave the phenylurea, m. p. 119–120°, colourless plates from aqueous alcohol. Mailhe (*Bull. Soc. chim.*, 1905, **33**, 966) gives m. p. 120° for *N*-phenyl-*N'*- α -methylbutylurea (Found : N, 13.6. Calc. for $C_{12}H_{18}ON_2$: N, 13.6%).

2-Nitro-3-methylpentadecane.—A solution of dodecylmagnesium bromide (from 55 g. of dodecyl bromide) in dry ether (250 c.c.) was added during 1 hour to a stirred solution of 2-nitrobut-2-ene (30 g.) in dry ether (150 c.c.) at 0–5°. The mixture was refluxed for 1 hour, cooled, and treated cautiously with aqueous acetic acid (120 c.c. of 20%). The mixture was stirred until all the magnesium salts had dissolved, and the ethereal layer was dried, concentrated, and the residue repeatedly fractionated in a vacuum to give the nitro-compound (20 g.) as a pale yellow oil, b. p. 111–115°/0.06 mm. (Found : C, 71.0; H, 12.1; N, 5.85. $C_{16}H_{33}O_2N$ requires C, 70.85; H, 12.2; N, 5.2%). This gave the Meyer test for a secondary nitro-compound and formed a crystalline sodium salt on treatment with alcoholic sodium hydroxide.

2-Amino-3-methylpentadecane.—The nitro-compound (10 g.) was catalytically reduced in methyl alcohol in the presence of Raney nickel at ordinary temperature and pressure. Distillation of the filtered solution gave the amine (5.5 g.) as a colourless oil, b. p. 158–160°/11 mm. (Found : equiv., 237. $C_{16}H_{33}N$ requires equiv., 241). An aqueous solution of the hydrochloride, on being boiled with excess potassium cyanate, deposited colourless crystals of 2-ureido-3-methylpentadecane, m. p. 122–123° (from alcohol) (Found : C, 71.4; H, 12.4; N, 9.9. $C_{17}H_{35}ON_2$ requires C, 71.8; H, 12.7; N, 9.9%).

2-Nitroisopropylcyclohexane.—cycloHexylmagnesium bromide (from 81.5 g. of cyclohexyl bromide) was brought into reaction with 1-nitroprop-1-ene (29 g.; this series, Part I) as described above for the preparation of 1-nitrohexane. After decomposition of the complex the ethereal layer was concentrated and the residue dissolved in alcohol (200 c.c.), treated with aqueous sodium hydroxide (35 c.c. of 32%) at 0–5°, the solution diluted with water (400 c.c.), and washed with ether. The aqueous solution was made acid to Congo-red with concentrated hydrochloric acid at 0–5° and extracted with ether. The extract was dried and distilled, giving 2-nitroisopropylcyclohexane as a pale yellow oil, b. p. 122°/16 mm. (Found : C, 63.4; H, 9.7; N, 8.2. $C_9H_{17}O_2N$ requires C, 63.15; H, 9.95; N, 8.2%).

2-Nitro-3-phenylbutane.—Phenylmagnesium bromide (from 51 g. of bromobenzene) was brought into reaction with 2-nitrobut-2-ene (20 g.) as described above for the preparation of 1-nitrohexane. After isolation in the usual manner the product was distilled under reduced pressure, giving impure 2-nitro-3-phenylbutane (22.5 g.), b. p. 118–120°/13 mm. This material, which appeared to contain some diphenyl, was not further purified but was reduced with hydrogen in methyl alcohol in the presence of Raney nickel at ordinary temperature and pressure. The filtered solution was acidified with hydrochloric acid and evaporated to dryness on the steam-bath, the residue dissolved in water, and washed with ether. The aqueous solution was then basified with concentrated sodium hydroxide and extracted with ether. The extract was dried (KOH) and distilled, giving the amine as a colourless oil (10.7 g.), b. p. 87°/12 mm. (Found : equiv., 147. $C_{10}H_{15}N$ requires equiv., 149). Reaction with picryl chloride gave 2-picrylamino-3-phenylbutane, m. p. 119–120°, yellow plates from alcohol (Found : N, 15.65. $C_{16}H_{15}O_6N_3$ requires N, 15.55%).

2-Nitro-3-phenylheptane.—2-Nitro-1-phenylprop-1-ene (32 g.; Alles, *J. Amer. Chem. Soc.*, 1932, **54**, 272) dissolved in dioxan (120 c.c.) was added during 1 hour to a stirred ethereal solution (150 c.c.) of butylmagnesium bromide (prepared from 42 g. of butyl bromide) at 0–5°. The mixture was stirred at 20° for 1 hour and the product isolated in the usual way. Distillation gave impure 2-nitro-3-phenylheptane (29 g.), b. p. 62–90°/0.02 mm., which was not further purified, but was reduced with hydrogen and Raney nickel in methyl alcohol. The filtered solution was acidified with hydrochloric acid and evaporated to dryness on the steam-bath; the residue was dissolved in water and washed with ether. The aqueous solution was basified with sodium hydroxide and the amine isolated with ether. Distillation gave 2-amino-3-phenylheptane as a colourless oil, b. p. 114–115°/9 mm. (Found : equiv., 191. $C_{13}H_{21}N$ requires equiv., 191). This material, apparently a mixture of stereoisomerides, gave a hydrochloride of indefinite m. p. (Found : Cl, 15.5. $C_{13}H_{21}N.HCl$ requires Cl, 15.6%). Attempts to prepare crystalline derivatives with benzoyl chloride, phenyl isocyanate, picryl chloride, and nitrourea failed.

1-Nitro-2-(2-furyl)hexane.—A solution of 1-nitro-2-(2-furyl)ethylene (14 g.; Thiele and Landers, *Annalen*, 1909, **369**, 303) in dioxan (70 c.c.) was added during 1 hour at 0–10° to a stirred solution (150 c.c.) of *n*-butylmagnesium bromide prepared from *n*-butyl bromide (34.5 g.). The solution was stirred.

at 20° for 18 hours, poured on ice, and the product isolated in the usual way, giving 1-nitro-2-(2-furyl)-hexane as a pale yellow oil (6.5 g.), b. p. 78—82°/0.4 mm. (Found : N, 7.2. $C_{10}H_{18}O_2N$ requires N, 7.1%).

1-Nitro-2-benzylcyclohexane.—An ethereal solution of benzylmagnesium chloride (prepared from 34 g. of benzyl chloride) was brought into reaction with 1-nitrocyclohexene (32 g.; Wieland *et al.*, *Annalen*, 1921, 424, 71) as described above for the preparation of 1-nitrohexane. Distillation of the product gave impure 1-nitro-2-benzylcyclohexane (23.5 g.), b. p. 91—115°/0.04 mm. This material, apparently containing 1 : 2-diphenylethane, was hydrogenated in the usual way over Raney nickel without further purification. The resulting amine was purified through its hydrochloride and finally distilled, giving a colourless oil (12.5 g.), b. p. 138—140°/11 mm. (Found : equiv., 191. Calc. for $C_{15}H_{21}N$: equiv., 189). This base, apparently a mixture of isomerides, was dissolved in benzene (50 c.c.) and shaken with 2*N*-hydrochloric acid (70 c.c.). After 45 minutes, the precipitated hydrochloride was collected; this appeared to be still a mixture, and no pure derivatives could be isolated from it. On standing overnight the mother liquor deposited a second precipitate which was collected and crystallised repeatedly from 2*N*-hydrochloric acid to give pure *cis*-2-benzylcyclohexylamine hydrochloride, m. p. 224°. This formed an acetyl derivative, m. p. 116°, and a benzoyl derivative, m. p. 155° (Found : C, 82.5; H, 8.25; N, 4.7. Calc. for $C_{20}H_{23}ON$: C, 81.9; H, 7.85; N, 4.8%). No m. p. depression was observed on admixture of these derivatives with authentic specimens prepared according to Schöpf and Boettcher (*Annalen*, 1926, 448, 1).

The authors thank Dr. H. A. Piggott and Mr. J. D. Rose for their interest and encouragement in this work.

291. Aliphatic Nitro-compounds. Part XII. Preparation and Reduction of 2-Nitroalkyl Cyanides.*

By G. D. BUCKLEY, R. L. HEATH, and J. D. ROSE.

Interaction of alkali-metal cyanides (or mixtures of these with hydrogen cyanide) and α -nitro-olefins yields 2-nitroalkyl cyanides. 2-Nitro-1-methylisopropyl cyanide, formed in 90% yield from 1-nitro-2-methylprop-1-ene and hydrogen cyanide-potassium cyanide, yields on catalytic reduction only minor quantities of the expected 2-amino-1-methylisopropyl cyanide and 1 : 3-diamino-2 : 2-dimethylpropane, the major products being 2-amino-1-methylisobutyramide and 5 : 5-dimethyl-2-(1-carbamylisopropyl)hexahydropyrimidine (III). 2-Nitropropyl cyanide, 2-nitroisopropyl cyanide, and 2-nitro-1-methylpropyl cyanide on reduction yield, in addition to the amino-cyanides, some of the corresponding amino-amides.

In connection with a general programme of work on the addition reactions of the α -nitro-olefins, a study of the formation of 2-nitroalkyl cyanides by interaction of metallic cyanides (or mixtures of these with hydrogen cyanide) with α -nitro-olefins was undertaken. The reduction of the nitroalkyl cyanides was investigated as a potential technical route to certain 1 : 3-diamines and β -amino-acids required for synthetic work in another connection.

The literature contains only one reference to the interaction of a metal cyanide with an α -nitro-olefin. Hollemann (*Rec. Trav. chim.*, 1904, 23, 283) showed that by interaction of β -nitrostyrene and potassium cyanide, two stereoisomerides of 1 : 4-dinitro-2-cyano-2 : 3-diphenylbutane (II) were formed.

The primary reaction in the formation of (II) must be the addition of hydrogen cyanide to the nitro-olefin, giving 2-nitro-1-phenylethyl cyanide (I), which by further reaction with nitrostyrene affords (II).

Interaction of 1- and 2-nitroprop-1-ene with aqueous potassium cyanide gave 2-nitroisopropyl cyanide and 2-nitro-n-propyl cyanide, respectively, but the yields were poor (10—15%), much of the olefin being lost by polymerisation in the alkaline reaction medium. 2-Nitrobut-2-ene, which polymerises much less readily than its lower homologues, gave a 50% yield of 2-nitro-1-methyl-n-propyl cyanide, and 75—90% yields of nitro-tert-butyl cyanide were obtained from 1-nitro-2-methylprop-1-ene and potassium cyanide, or mixtures of potassium cyanide with hydrogen cyanide. It was shown that hydrogen cyanide alone will not add to the ethylenic linkage of this nitro-olefin, but in the presence of small quantities of potassium cyanide (5—20% of the total of CN ion) excellent yields are obtained.

Surprising results were obtained in the reduction of the 2-nitroalkyl cyanides. Catalytic

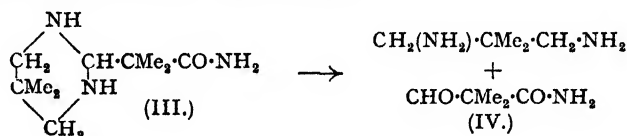

* Patent application pending.

reduction of 2-nitroisopropyl cyanide in methyl alcohol at ordinary temperature and pressure in presence of Raney nickel catalyst gave a low yield of β -aminoisobutyramide. Similar reduction of 2-nitro-1-methyl-*n*-propyl cyanide afforded a mixture of the expected aminoalkyl cyanide and β -amino- α -methylbutyramide, whilst reduction in the presence of anhydrous ammonia under pressure gave the amino-amide and some 1 : 3-diamino-2-methylpropane. In none of the above cases was the yield of reduction products good, and attention was turned for closer study to the more readily available nitro-*tert*-butyl cyanide. Chemical reduction of this with iron and hydrochloric acid gave a 65% yield of amino-*tert*-butyl cyanide and 5% of β -amino- α -dimethylpropionamide. Catalytic reduction at ordinary temperature and pressure of the nitroalkyl cyanide in methyl alcohol with a 5% palladium on calcium carbonate catalyst gave the amino-amide in 90% yield and in methyl alcoholic ammonia at 100°/100 atms. with Raney nickel, 20% of the amino-amide and 15% of 1 : 3-diamino-2 : 2-dimethylpropane were obtained. On reduction in methyl alcohol with hydrogen at ordinary temperature and pressure in the presence of Raney nickel, four products were obtained : (a) the aminoalkyl cyanide (1.5%), (b) the diamine (1.5%), (c) the amino-amide (50%), and (d) a solid, $C_{10}H_{21}ON_3$ (20%), which separated as pearly plates, m. p. 150°, when the filtered reduction solution was concentrated.

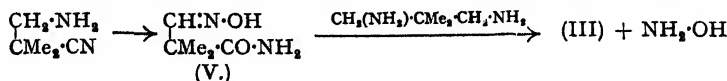

In attempting to prepare derivatives of the solid (d), it was observed that by the action of reagents for amines, the derivatives (*hydrochloride*, *picrate*, *benzoyl* derivative) which were obtained were identical with those formed directly from 1 : 3-diamino-2 : 2-dimethylpropane. It was, therefore, clear that the solid was a derivative of this diamine which was easily hydrolysed by acid and alkaline reagents, thus :

By addition of a 2*N*-hydrochloric acid solution of 2 : 4-dinitrophenylhydrazine to the base, $C_{10}H_{21}ON_3$, in dilute hydrochloric acid, a 2 : 4-dinitrophenylhydrazone, $C_{11}H_{13}O_5N_5$, was obtained (*i.e.*, the derivative of a ketone or aldehyde, $C_5H_9O_2N$). This is formulated as α -carbamyloisobutaldehyde (IV), and the substance, $C_{10}H_{21}ON_3$, as 5 : 5-dimethyl-2-(1-carbamyloisopropyl)-hexahydropyrimidine (III); the ease of fission of substituted hexahydropyrimidines is well recognised (*cf.* Veer, *Rec. Trav. chim.*, 1938, 57, 989).

The mechanism of formation of the hexahydropyrimidine is obscure; Veer (*loc. cit.*) showed that derivatives of 1 : 3-diaminopropane condense with aldehydes merely on warming in alcoholic solution, but it is difficult to visualise conditions during a catalytic reduction which would convert the primary nitro-group, $-CH_2 \cdot NO_2$, into the aldehyde group, $-CHO$. It is considered more probable that the intermediate in this case is β -carbamyloisobutaldoxime (V), which condenses with the diaminopropane with loss of hydroxylamine, thus :

The formation of amino-amides by mild catalytic reduction of the 2-nitroalkyl cyanides is surprising. It is thought that this is not simple addition of water to the aminoalkyl cyanide; an experiment was carried out in which nitro-*tert*-butyl cyanide was shaken at room temperature in methyl alcohol with water (2 mols.) and Raney nickel (*i.e.*, the conditions of the hydrogenation). The aminoalkyl cyanide was recovered unchanged. It is possible that amide formation proceeds through an *isooxazole* as intermediate product (*isooxazoles* are known to undergo fission on hydrogenation), but no experimental proof for this can be given.

EXPERIMENTAL.

Analyses are by Mr. E. S. Morton. M. ps. are uncorrected.

2-Nitroisopropyl Cyanide.—1-Nitroprop-1-ene (50 g.; this series, Part I) in alcohol (240 c.c.) was added dropwise to a well-stirred solution of potassium cyanide (40 g.) in water (300 c.c.) at -5° to 0° . The solution was stirred at 0° for a further 4 hours, acidified at $0-5^\circ$ with 5*N*-hydrochloric acid (130 c.c.), concentrated under reduced pressure at 40° to 300 c.c., and after isolation with ether the cyanide (16.4 g.; 25%), b. p. $68-70^\circ/0.5$ mm., was obtained (Found: C, 42.6; H, 5.2; N, 23.9. $C_4H_7O_2N_2$ requires C, 42.1; H, 5.3; N, 24.5%).

β -Aminoisobutyramide.—The cyanide (3.25 g.) in methyl alcohol (50 c.c.) was shaken in hydrogen

at 25°/760 mm. in the presence of Raney nickel. Absorption (1916 c.c. of hydrogen) was complete in 3½ hours. The catalyst was separated, the alcohol removed, and the product distilled, giving the amide (0.44 g.; 15%), b. p. 75–82°/0.3 mm., which was identified as the *picrate*, m. p. 232° (Found: N, 20.6. $C_8H_{10}ON_2 \cdot C_6H_5O_2N_3$ requires N, 21.1%).

2-Nitro-n-propyl Cyanide.—This compound was prepared from 2-nitroprop-1-ene (50 g.; this series, Part I) and sodium cyanide (28.2 g.) as described for the *iso*-derivative above; it was obtained as a straw-coloured liquid (10 g.; 15%), b. p. 81–82°/0.5 mm. (Found: C, 42.7; H, 5.0. $C_4H_7O_2N_2$ requires C, 42.1; H, 5.3%).

2-Nitro-1-methyl-n-propyl Cyanide.—This compound was prepared from 2-nitrobut-2-ene (58 g.; this series, Part III) in alcohol (500 c.c.) and potassium cyanide (38 g.) in water (300 c.c.) at 10–20°. Isolation in the usual way yielded the cyanide (32 g.; 50%) as a pale yellow, mobile oil, b. p. 61–65°/0.2 mm. (Found: C, 47.0; H, 6.4. $C_5H_9O_2N_2$ requires C, 46.9; H, 6.2%).

Reduction of 2-Nitro-1-methyl-n-propyl Cyanide.—(a) *With Raney nickel at ordinary pressure.* The cyanide (10.4 g.) in methyl alcohol (80 c.c.) was shaken in hydrogen at 20°/750 mm. in the presence of Raney nickel. Absorption was 4930 c.c. of hydrogen at 0°/760 mm. [Calc. (3 mols.), 5460 c.c.]. The catalyst was separated and the product distilled, giving: (i) 2-Amino-1-methyl-n-propyl cyanide, b. p. 30°/0.05 mm. (0.5 g.), characterised as its *hydrochloride*, white crystals from alcohol-ether, m. p. 156° (Found: C, 44.6; H, 8.3; N, 20.8. $C_5H_{10}N_2 \cdot HCl$ requires C, 44.6; H, 8.3; N, 20.8%). (ii) β -Amino- α -methylbutyramide, b. p. 145–155°/15 mm., 95–100°/0.05 mm. (1.7 g.), which solidified on keeping and after crystallisation from dry benzene had m. p. 62–63°. The amide was extremely deliquescent and satisfactory analyses could not be obtained. Neither the hydrochloride nor the *picrate* could be obtained in a crystalline condition, and the amide was characterised as the *picrolonate*, m. p. 214° (Found: N, 22.1. $C_5H_{10}ON_2 \cdot C_{10}H_8O_4N_4$ requires N, 22.1%).

(b) *With Raney nickel and anhydrous ammonia under pressure.* The cyanide (23 g.) in methyl alcohol (250 c.c.) and anhydrous ammonia (70 g.) was heated at 100° with hydrogen (initial pressure, 100 atms.) in an internally agitated stainless steel autoclave for 1 hour. The filtered solution was made acid to Congo-red with hydrochloric acid and evaporated to dryness at 40° under reduced pressure. The residue was treated with excess of aqueous potassium hydroxide and the product isolated with ether, giving: (i) 1:3-diamino-2-methylpropane, b. p. 60–70°/15 mm. (2 g.) (Found: equiv., 50. Calc.: 51); and (ii) β -amino- α -methylbutyramide, b. p. 145–155°/15 mm., m. p. 62–63°.

Nitro-tert-butyl Cyanide.—(a) *From 1-nitro-2-methylprop-1-ene and potassium cyanide.* 1-Nitro-2-methylprop-1-ene (101 g.; Levy and Scaife, in the press) in alcohol (500 c.c.) was added slowly to a stirred aqueous solution of potassium cyanide (65 g. in 500 c.c.) at 20–25°. Stirring was continued for 6 hours and the mixture then acidified with 5*N*-hydrochloric acid (240 c.c.) at 5–10°. The white, crystalline precipitate was collected, washed with cold water and recrystallised from ether, giving *nitro-tert-butyl cyanide* (96 g.; 75%), m. p. 42°, b. p. 66–67°/0.2 mm. (Found: C, 47.1; H, 6.1; N, 21.3. $C_5H_9O_2N_2$ requires C, 46.9; H, 6.2; N, 21.9%).

(b) *From 1-nitro-2-methylprop-1-ene, hydrogen cyanide, and potassium cyanide.* A mixture of the nitro-olefin (10.1 g.), hydrogen cyanide (6 g.), and potassium cyanide (0.325 g.; 5%) in 50% aqueous alcohol (50 c.c.) was stirred at room temperature for 24 hours. Water (50 c.c.) was then added and the solution at 0–5° made acid to Congo-red with hydrochloric acid. The precipitated cyanide was isolated with ether and recrystallised from ether, m. p. 42°. Yield, 10.3 g. (83%). In this preparation, the use of 1% of potassium cyanide reduced the yield to 10%; with 20% of potassium cyanide the yield was 87%; in the absence of potassium cyanide (hydrogen cyanide alone) no nitroalkyl cyanide was obtained.

(c) *From nitro-tert-butyl acetate and potassium cyanide.* Nitro-tert-butyl acetate (8 g.; this series, Part XVIII) was added dropwise to a vigorously stirred aqueous solution of potassium cyanide (4 g. in 25 c.c.) at 25–30°. Stirring was continued for 16 hours at 30°, the solution acidified at 0–5° with 5*N*-hydrochloric acid, and the precipitated cyanide crystallised from ether, m. p. 42°. Yield, 2.5 g. (40%).

Reduction of Nitro-tert-butyl Cyanide.—(a) *With iron and hydrochloric acid.* A mixture of iron filings (35 g.), concentrated hydrochloric acid (10 c.c.), and water (75 c.c.) was allowed to react at 60–70° until evolution of hydrogen ceased. The cyanide (21 g.) in alcohol (50 c.c.) was then added at a rate sufficient to maintain the temperature of the vigorously stirred mixture at 60–70°, and stirring was continued at the same temperature for a further 8 hours. The mixture was filtered, acidified with concentrated hydrochloric acid, and evaporated to dryness, and the free bases, liberated by addition of an excess of 50% aqueous potassium hydroxide, were isolated with ether. Distillation gave: (i) *Amino-tert-butyl cyanide* (10.2 g.; 65%), b. p. 63°/15 mm., m. p. 10° (Found: C, 61.5; H, 9.7. $C_5H_{11}N_2$ requires C, 61.2; H, 10.2%); *hydrochloride*, from alcohol, m. p. 260° (Found: C, 44.5; H, 8.2; N, 20.6. $C_5H_{10}N_2 \cdot HCl$ requires C, 44.6; H, 8.2; N, 20.8%); *picrate*, from water, m. p. 183° (Found: C, 40.3; H, 3.8; N, 21.4. $C_5H_{10}N_2 \cdot C_6H_5O_2N_3$ requires C, 40.4; H, 3.9; N, 21.4%); *benzoyl derivative*, from alcohol, m. p. 122° (Found: C, 71.3; H, 6.6; N, 13.9. $C_{11}H_{14}ON_2$ requires C, 71.3; H, 6.6; N, 13.9%). Reduction of this aminoalkyl cyanide by shaking in methyl-alcoholic solution with hydrogen and Raney nickel at ordinary temperature and pressure afforded 1:3-diamino-2:2-dimethylpropane, b. p. 65°/15 mm., 153°/760 mm. (Found: C, 58.4; H, 13.6; N, 27.0. $C_6H_{14}N_2$ requires C, 58.8; H, 13.7; N, 27.4%); dihydrochloride, m. p. 259° [Komppa and Seron (*Ann. Acad. Sci. Fennica*, 1933, 374, No. 7, 8; cf. *Chem. Abs.*, 1933, 3964) give m. p. 280–281°] (Found: C, 34.5; H, 8.6; N, 15.7; Cl, 40.1. Calc. for $C_6H_{14}N_2 \cdot 2HCl$: C, 34.3; H, 9.1; N, 16.0; Cl, 40.6%); dipicrate, m. p. 234° (Komppa and Seron, *loc. cit.*, give m. p. 240°) (Found: C, 36.6; H, 3.6; N, 19.8. Calc. for $C_6H_{14}N_2 \cdot 2C_6H_5O_2N_3$: C, 36.4; H, 3.6; N, 20.0%); *dibenzoyl derivative*, long needles from aqueous alcohol, m. p. 152° (Found: C, 73.7; H, 7.3; N, 9.0. $C_{18}H_{22}O_4N_4$ requires C, 73.5; H, 7.1; N, 9.0%). (ii) β -Amino- α -dimethylpropionamide (1 g.; 5%), b. p. 145°/15 mm., which solidified and after crystallisation from dry benzene had m. p. 74–75° (Found: equiv. by titration, 115. Calc.: 116). This compound was highly deliquescent and satisfactory analyses could not be obtained; it was characterised as the following derivatives: *hydrochloride*, fine needles from absolute alcohol, m. p. 172° (Found: C, 39.6; H, 8.7;

N, 17.8; Cl, 23.3. $C_8H_{11}ON_2.HCl$ requires C, 39.5; H, 8.5; N, 18.3; Cl, 23.3%; *hydrobromide*, plates from absolute alcohol, m. p. 202° (Found: C, 30.5; H, 6.2; N, 14.1; Br, 40.8. $C_8H_{11}ON_2.HBr$ requires C, 30.5; H, 6.6; N, 14.2; Br, 40.6%); *picrate*, flat prisms from alcohol, m. p. 190° (Found: C, 38.4; H, 4.2; N, 20.4. $C_8H_{11}ON_2.C_6H_3O_7N_3$ requires C, 38.3; H, 4.3; N, 20.3%); *phenylurea*, prisms from alcohol, m. p. $199-200^\circ$ (Found: C, 61.2; H, 7.0; N, 17.2. $C_{11}H_{17}O_2N_2$ requires C, 61.2; H, 7.2; N, 17.8%). The *benzoyl* derivative, prisms from alcohol-ether, m. p. 151° (Found: C, 65.5; H, 7.2; N, 12.6. $C_{12}H_{15}O_2N_2$ requires C, 65.4; H, 7.3; N, 12.7%), on being heated with excess of thionyl chloride, gave 2-benzamido-1:1-dimethyl-*tert*-butyl cyanide, m. p. 122° , identical with that described above.

(b) *Reduction with hydrogen and Raney nickel at ordinary pressure.* The nitroalkyl cyanide (42 g.) in methyl alcohol (450 c.c.) was shaken in hydrogen in presence of Raney nickel at ordinary pressure and temperature. Absorption was 22.7 l. of hydrogen at N.T.P. [Calc. (3 mols.), 22.4 l.]. The catalyst was separated and the filtrate concentrated, giving a solid (A) and a liquid, separated by filtration. The liquid was distilled, giving the following: (i) Amino-*tert*-butyl cyanide (0.5 g.; 1.5%), m. p. 10° . (ii) 1:3-Diamino-2:2-dimethylpropane (0.5 g.; 1.5%); dihydrochloride, m. p. 259° ; dipicrate, m. p. 234° . (iii) β -Amino- $\alpha\alpha$ -dimethylpropionamide (19 g.; 50%), m. p. $74-75^\circ$. The solid (A), above, recrystallised from absolute alcohol, gave 5:5-dimethyl-2-(1-carbamylisopropyl)hexahydropyrimidine (6.5 g.; 20%) in pearly plates, m. p. 150° (Found: C, 60.2; H, 10.1; N, 20.6. $C_{10}H_{15}ON_2$ requires C, 60.3; H, 10.5; N, 21.0%). On addition of a dry, ethereal solution of hydrogen chloride to the base in alcohol at $0-10^\circ$, 1:3-diamino-2:2-dimethylpropane dihydrochloride, m. p. and mixed m. p. with an authentic specimen 259° , separated in 42% yield. Similarly, addition of hot, aqueous picric acid to an alcoholic solution of the hydropyrimidine gave 1:3-diamino-2:2-dimethylpropane dipicrate, m. p. and mixed m. p. 234° , and benzooylation by the Schotten-Baumann procedure gave 1:3-dibenzamido-2:2-dimethylpropane, m. p. and mixed m. p. 152° . Addition of 2:4-dinitrophenylhydrazine in 2N-hydrochloric acid to a solution of the pyrimidine in hydrochloric acid gave a pale yellow, crystalline precipitate, which, crystallised from methyl alcohol, yielded β -carbamylisobutaldehyde 2:4-dinitrophenylhydrazone, m. p. 196° (Found: C, 44.7; H, 4.4; N, 23.6. $C_{11}H_{13}O_5N_5$ requires C, 44.7; H, 4.4; N, 23.7%).

(c) *Reduction with hydrogen and palladium.* The nitro-cyanide (10 g.) in methyl alcohol (50 c.c.) was shaken in hydrogen with a 5% palladium on calcium carbonate catalyst at ordinary pressure. Absorption was 5.2 l. of hydrogen at N.T.P. [Calc. (3 mols.), 5.25 l.]. The catalyst was removed and the solution distilled, yielding β -amino- $\alpha\alpha$ -dimethylpropionamide, m. p. $74-75^\circ$ (8.0 g.; 89%).

(d) *Reduction with hydrogen and Raney nickel in presence of anhydrous ammonia.* The nitro-cyanide (45 g.) in methyl alcohol (250 c.c.) and anhydrous ammonia (140 g.) was heated at 100° in an internally agitated, stainless steel autoclave with hydrogen at 100 atms. initial pressure and Raney nickel (10 g.). Hydrogenation was complete in 1 hour. After evaporation of the ammonia, the catalyst was removed and the product distilled, giving: (i) 1:3-Diamino-2:2-dimethylpropane, b. p. $65^\circ/15$ mm. (5.5 g.; 15%). (ii) β -Amino- $\alpha\alpha$ -dimethylpropionamide, m. p. $74-76^\circ$ (8.2 g.; 20%).

β -Amino- $\alpha\alpha$ -dimethylpropionic Acid.— β -Amino- $\alpha\alpha$ -dimethylpropionamide (9.2 g.) was refluxed for 4 hours with 40% sulphuric acid (90 c.c.). The solution was diluted with water (300 c.c.) and barium carbonate (slight excess calculated on the sulphuric acid) was added slowly to the boiling solution through which a current of steam was passed to remove the ammonia. The excess of barium carbonate was decomposed by neutralisation (to Congo-red) with 2N-sulphuric acid, and the barium sulphate removed by filtration. The filtrate was concentrated to 75 c.c., and traces of sulphuric acid were precipitated with lead carbonate, the lead sulphate was filtered off, and the filtrate saturated with hydrogen sulphide. After removal of lead sulphide, the filtrate was concentrated and yielded β -amino- $\alpha\alpha$ -dimethylpropionic acid, which separated from aqueous alcohol as large hexagonal prisms, m. p. 246° (decomp.) in 82% yield (Kohn and Schmidt, *Monatsh.*, 1907, 28, 1056, give decomp. ca. 220°) (Found: C, 51.1; H, 9.4; N, 12.3. Calc. for $C_8H_{11}O_2N$: C, 51.3; H, 9.4; N, 12.0%).

Methyl β -Amino- $\alpha\alpha$ -dimethylpropionate.—The acid was esterified in methyl alcohol with dry hydrogen chloride in the usual way; evaporation of the methyl alcohol yielded the *methyl ester hydrochloride*, m. p. 164° (80% yield) (Found: C, 43.0; H, 8.2; N, 8.2. $C_8H_{13}O_2N.HCl$ requires C, 43.0; H, 8.4; N, 8.4%). Addition of 10N-sodium hydroxide to an aqueous solution of the hydrochloride, followed by isolation with ether and distillation, afforded the *methyl ester*, b. p. $57^\circ/11$ mm., which separated from dry ether as highly deliquescent prisms, m. p. 64° (Found: C, 54.8; H, 9.9; N, 10.5. $C_8H_{13}O_2N$ requires C, 55.0; H, 9.9; N, 10.7%). The ester was completely unchanged after standing for 2 days at 0° with methyl alcoholic ammonia; with concentrated aqueous ammonia, at 60° for 3 days, hydrolysis to the acid occurred. The *ethyl ester hydrochloride*, similarly formed, had m. p. 91° (Found: C, 45.6; H, 8.4; N, 7.8; Cl, 19.7. $C_7H_{13}O_2N.HCl$ requires C, 46.2; H, 8.8; N, 7.7; Cl, 19.7%).

β -Benzamido- $\alpha\alpha$ -dimethylpropionic acid, m. p. 151° (Kohn and Schmidt, *loc. cit.*, give m. p. $149-151^\circ$) (3 g.) was treated with freshly distilled thionyl chloride (6.5 c.c.; 6 mols.) and the reaction completed by 1 hour's boiling under reflux. The excess of thionyl chloride was removed under reduced pressure at $70-80^\circ$, and to the residual, pale yellow oil, saturated methyl-alcoholic ammonia (25 c.c.) was added at 0° . The solution was evaporated, the residual solid triturated with water to remove ammonium chloride, and the residue, crystallised from aqueous alcohol, gave a small yield of *benzamido-tert*-butyl cyanide identical with that described above, m. p. and mixed m. p. 122° . Repetition of this experiment with only one mol. of thionyl chloride in benzene, and treatment of the crude acid chloride with aqueous (d 0.88) ammonia, gave 90% of β -benzamido- $\alpha\alpha$ -dimethylpropionamide, m. p. 151° , identical with the benzoyl derivative of the amino-amide (see above).

The authors wish to acknowledge the interest and advice of Dr. H. A. Piggott in this work.

292. Aliphatic Nitro-compounds. Part XIII. Preparation of 3-Nitro-1-arylalkyl Cyanides by Interaction of Arylmethyl Cyanides and α -Nitro-olefins.*

By G. D. BUCKLEY, F. G. HUNT, and A. LOWE.

Arylmethyl cyanides, but not 1-arylethyl cyanides, react with α -nitro-olefins in presence of alkali alkoxides (preferably potassium *tert.*-amyloxyde) to give 3-nitro-1-arylalkyl cyanides. 2-Nitroalkyl esters may be used in place of nitro-olefins, e.g., 1-nitro-2-methylprop-1-ene or nitro*tert.*-butyl nitrate reacts with benzyl cyanide to give 3-nitro-1-phenyl-2:2-dimethylpropyl cyanide (II).

THE use of α -nitro-olefins as the unsaturated component in reactions of the Michael type has been described in earlier parts in this series and elsewhere. Active methylene compounds which have been used successfully in such reactions include primary and secondary nitro-paraffins (Part VIII), ethyl malonate (Kohler *et al.*, *J. Amer. Chem. Soc.*, 1919, **41**, 764; 1926, **48**, 1770), and acetone (Hass and Riley, *Chem. Reviews*, 1943, **32**, 373), and this type of reaction has now been extended to the preparation of 3-nitro-1-arylalkyl cyanides by addition of arylmethyl cyanides to α -nitro-olefins.

Benzyl cyanide reacted readily with 1-nitro-2-methylprop-1-ene in the presence of sodium methoxide to give 3-nitro-1-phenyl-2:2-dimethylpropyl cyanide (II) in 12% yield, but by using potassium *tert.*-amyloxyde in place of the methoxide catalyst the yield was raised to 60%. From *p*-bromobenzyl cyanide and 1-naphthylmethyl cyanide, with the amyloxyde catalyst, 3-nitro-1-*p*-bromophenyl-2:2-dimethylpropyl cyanide (III) and 3-nitro-1-(1-naphthyl)-2:2-dimethylpropyl cyanide (IV) were obtained in 48% and 70% yield respectively.

The adducts to 2-nitrobut-2-ene and 1-nitrocyclohexene were obtained as viscous oils from which it was difficult to isolate the pure diastereoisomerides: thus, benzyl cyanide with 2-nitrobut-2-ene gave 3-nitro-1-phenyl-2-methyl-*n*-butyl cyanide (I) and *p*-bromobenzyl cyanide added to 1-nitrocyclohexene to form 2-nitro-1-(*p*-bromo- α -cyanobenzyl)cyclohexane (V) from which a crystalline isomer was isolated in small yield and with considerable difficulty. An attempt to add 1-phenylethyl cyanide (Meyer, *Annalen*, 1899, **250**, 123) to 1-nitro-2-methylprop-1-ene in the presence of potassium *tert.*-amyloxyde failed.

(I.)

(II.)

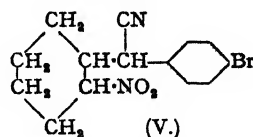

(VI.)

(III.)

(IV.)

(V.)

Esters of 2-nitro-alcohols yield nitro-olefins on treatment with alkalis, and it has been shown that such esters can be used instead of nitro-olefins in addition reactions provided that sufficient alkali is present to neutralise the liberated acid. Nitro-*tert.*-butyl nitrate reacted with 2 mols. of the potassium salt of benzyl cyanide to give 3-nitro-1-phenyl-2:2-dimethylpropyl cyanide identical with the product obtained from 1-nitro-2-methylprop-1-ene, and under similar conditions 2-nitroisopropyl acetate gave 3-nitro-1-phenyl-2-methylpropyl cyanide (VI).

The reaction is of fairly general application for the preparation of 3-nitro-1-arylalkyl cyanides and is complementary to the method of preparation described in Part XIV of this series. The two methods in conjunction make possible the preparation of a wide variety of these hitherto inaccessible compounds.

EXPERIMENTAL.

Microanalyses are by Mr. E. S. Morton. All m. ps. are uncorrected.

3-Nitro-1-phenyl-2-methyl-*n*-butyl Cyanide (I).—Benzyl cyanide (60 g.) was run into a solution of sodium methoxide [from sodium (12 g.) in methyl alcohol (200 c.c.)] at 20° and a solution of 2-nitrobut-2-ene (50 g.; this series, Part III) in methyl alcohol (100 c.c.) added dropwise during 1 hour at 5–10°. The mixture was heated at 60° for 18 hours, poured into water, and extracted with ether. The extract was washed with water and discarded, and the combined aqueous solutions were acidified

* Patent application pending.

with acetic acid (50 c.c.) and extracted with ether. The extract was dried and fractionated, giving the cyanide as a yellow oil (28.5 g.), b. p. 129—134°/0.2 mm. (Found: N, 13.15. $C_{11}H_{14}O_2N_2$ requires N, 12.85%).

3-Nitro-1-phenyl-2:2-dimethylpropyl Cyanide (II).—(a) From 1-nitro-2-methylprop-1-ene. To a stirred, ice-cooled solution of potassium *tert*-amyloxyde (from 8 g. of potassium), benzyl cyanide (23.5 g.) was added at 5—10°. 1-Nitro-2-methylprop-1-ene (20 g.; Levy and Scaife, in the press) was then added dropwise during 1 hour at 5—10°, and the reaction was completed by stirring at 60° for 2 hours. After cooling, the mixture was diluted with water and extracted with ether. The ethereal extract was washed with water and discarded, and the combined aqueous solutions were acidified with acetic acid (13 c.c.) and extracted with ether. The extract was washed with sodium hydrogen carbonate solution, dried, evaporated, and the residue (25 g.; 60% yield), consisting of almost pure 3-nitro-1-phenyl-2:2-dimethylpropyl cyanide, was left in a desiccator until completely solid. Crystallisation from a little methyl alcohol gave colourless needles, m. p. 59° (Found: C, 66.15; H, 5.95; N, 12.9. $C_{12}H_{14}O_2N_2$ requires C, 66.05; H, 6.4; N, 12.85%).

(b) From nitro-*tert*-butyl nitrate. A solution of potassium *tert*-amyloxyde [from potassium (2 g.) in *tert*-amyl alcohol (40 c.c.)] was treated with benzyl cyanide (5.85 g.) as before. Nitro-*tert*-butyl nitrate (4.1 g.; Levy and Scaife, in the press) in *tert*-amyl alcohol (5 c.c.) was added during 1 hour at 5—10°, and the mixture was then stirred at 60° for 2 hours and worked up as before. The product, m. p. 59°, was identical with that prepared above from 1-nitro-2-methylprop-1-ene.

3-Nitro-1-p-bromophenyl-2:2-dimethylpropyl Cyanide (III).—*p*-Bromobenzyl cyanide (9.8 g.) was brought into reaction with 1-nitro-2-methylprop-1-ene (5.05 g.) as described for benzyl cyanide. After several days in a desiccator the product solidified (7.1 g.; 48% yield), and crystallisation from methyl alcohol gave colourless needles of 3-nitro-1-p-bromophenyl-2:2-dimethylpropyl cyanide, m. p. 72—74° (Found: N, 9.4; Br, 27.55. $C_{11}H_{11}O_2N_2Br$ requires N, 9.4; Br, 26.9%).

3-Nitro-1-(1-naphthyl)-2:2-dimethylpropyl Cyanide (IV).—1-Naphthylmethyl cyanide (5 g.) was brought into reaction with 1-nitro-2-methylprop-1-ene (3 g.) as described for benzyl cyanide. The product (5.5 g.; 70% yield), isolated as before, solidified on removal of the ether. After two recrystallisations from alcohol (charcoal) the cyanide was obtained as long, colourless needles, m. p. 116° (Found: C, 71.7; H, 6.0; N, 10.4. $C_{16}H_{15}O_2N_2$ requires C, 71.65; H, 6.0; N, 10.4%).

3-Nitro-1-phenyl-2-methylpropyl Cyanide (VI).—A solution of potassium *tert*-amyloxyde [from potassium (8 g.) in *tert*-amyl alcohol (160 c.c.)] was treated with benzyl cyanide (23.5 g.) as before. 2-Nitroisopropyl acetate (14.6 g.; Schmidt and Rutz, *Ber.*, 1928, **61**, 2142) was then added during 1 hour at 5—10°, and the resulting solution was stirred at 60° for 2 hours, cooled to 20°, and diluted with water. Isolation in the usual way yielded 3-nitro-1-phenyl-2-methylpropyl cyanide as a pale yellow oil (6.7 g.; 25% yield), b. p. 122—126°/0.15 mm. (Found: C, 65.3; H, 5.55; N, 14.2. $C_{11}H_{13}O_2N_2$ requires C, 64.7; H, 5.9; N, 13.75%).

2-Nitro-1-(p-bromo- α -cyanobenzyl)cyclohexane (V).—1-Nitrocyclohexene (14 g.; Wieland *et al.*, *Annalen*, 1921, **424**, 71) was brought into reaction with *p*-bromobenzyl cyanide (21.6 g.) in presence of potassium *tert*-amyloxyde as previously described. The crude product, isolated as before, was a viscous oil (10.7 g.), apparently a mixture of diastereoisomers. After several days in a desiccator, it partly crystallised, and was then treated with a little alcohol and the crystals were collected (2.9 g.). Recrystallisation from methyl alcohol gave the compound as colourless granules, m. p. 103—104° (Found: N, 8.75; Br, 25.2. $C_{14}H_{15}O_2N_2Br$ requires N, 8.65; Br, 24.75%).

HEXAGON HOUSE, BLACKLEY, MANCHESTER, 9.

[Received, January 23rd, 1947.]

293. Aliphatic Nitro-compounds. Part XIV. Preparation of 3-Nitroalkyl Cyanides by Reaction of Nitro-paraffins with Unsaturated Cyanides.*

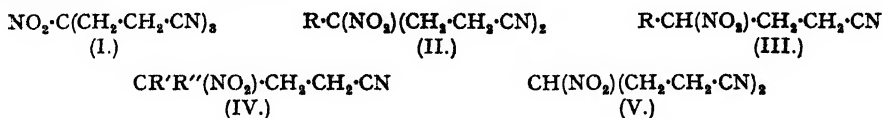

By G. D. BUCKLEY, T. J. ELLIOTT, F. G. HUNT, and A. LOWE.

A series of 3-nitroalkyl cyanides is prepared by the interaction of vinyl cyanide with primary and secondary nitro-paraffins in the presence of alkali. Both propenyl and allyl cyanide react with 1-nitropropane to give 3-nitro-2-methyl-n-amyl cyanide and with 2-nitropropane to give 3-nitro-2:3-dimethyl-n-butyl cyanide. α -Cyanostilbenes react with primary nitro-compounds in presence of secondary aliphatic amines to give 3-nitro-1:2-diaryllalkyl cyanides, e.g., α -cyanostilbene and nitromethane give 3-nitro-1:2-diphenylpropyl cyanide (VIII; R = H).

WHEN this work was carried out only two 3-nitroalkyl cyanides had been reported: 3-nitropropyl cyanide, prepared by Henry (*Bull. Acad. Sci. Belg.*, 1895, **36**, 152) by the action of silver nitrite on 3-iodopropyl cyanide, and nitrotris-(2-cyanoethyl)methane (I) prepared by Bruson and Reiner (*J. Amer. Chem. Soc.*, 1943, **65**, 23) by addition of nitromethane to vinyl cyanide (acrylonitrile). As large quantities of 3-nitroalkyl cyanides were required in connection with other investigations, we decided to extend the application of Bruson's method to other olefins and nitro-paraffins.

* Patent application pending.

Since our work was completed, Bruson (U.S.P. 2,361,259) has reported the addition of nitro-paraffins to vinyl cyanide in an inert solvent (e.g., dioxan or *tert.*-butyl alcohol), preferably at about 40° and in the presence of a small amount of alkali such as sodium hydroxide or a quaternary ammonium base as catalyst. In this way nitromethane gave the tris-adduct (I), other primary nitro-paraffins gave mixtures of bis- (II) and mono-adducts (III), whereas secondary nitro-paraffins gave mono-adducts (IV).

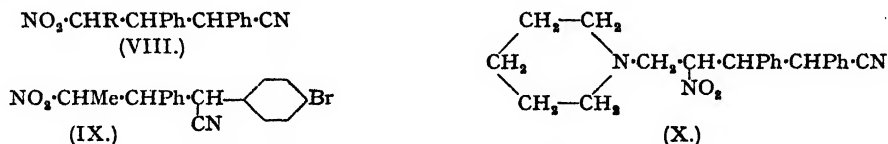

We have found it more convenient to effect the addition by refluxing an alcoholic solution of the cyanide, nitro-paraffin, and catalyst for a short time. The yields of mono-adducts (type III) from primary nitro-paraffins are improved by using a full molecular proportion of alkali as condensing agent, and with this technique, the bis-adduct to nitromethane (V) has been obtained.

The following new 4-nitro-cyanides have been made by this method: 1-nitro-1-(2-cyanoethyl)-cyclohexane, 3-nitro-4-methoxy-4-phenyl-3-methyl-*n*-butyl cyanide (VI), 3-nitro-5-*n*-butylsulphonyl-3-methyl-*n*-amyl cyanide, and 3-nitro-1:5-dicyanopentane. The known 3-nitro-3-methyl-*n*-butyl cyanide and 3-nitro-*n*-butyl cyanide (cf. Bruson, *loc. cit.*) have been prepared by the modified method: the first of these has been converted into its iminoethyl ether and amidine hydrochloride, and the second has been hydrolysed with acid to 3-keto-*n*-butyl cyanide (lævulonitrile).

The general method of addition has been extended by the use of substituted vinyl cyanides. Thus 2-nitropropane reacted with isopropenyl cyanide (methacrylonitrile) in presence of a little methyltriethylammonium hydroxide to give 3-nitro-1:3-dimethyl-*n*-butyl cyanide and with propenyl cyanide (crotononitrile) to give the isomeric 3-nitro-2:3-dimethyl-*n*-butyl cyanide, which was also formed by interaction of allyl cyanide and 2-nitropropane. Similarly, both propenyl and allyl cyanide reacted with 1-nitropropane to give 3-nitro-2-methyl-*n*-amyl cyanide (VII), the identity of the products being established by hydrolysis to 3-keto-2-methyl-*n*-amyl cyanide, which was characterised as the 2:4-dinitrophenylhydrazone. The allyl cyanide was presumably isomerised to propenyl cyanide by the alkaline catalyst before reaction with the nitro-paraffin, but a curious feature was that in both cases much higher yields of nitro-cyanide were obtained from allyl cyanide than from propenyl cyanide.

Aryl substituted vinyl cyanides behaved in an anomalous manner. Attempts to cause nitroethane to react with α -cyanostilbene in presence of strong alkalis failed, but by using a secondary aliphatic amine as catalyst 3-nitro-1:2-diphenyl-*n*-butyl cyanide (VIII; R = Me) was produced in 60% yield.

Similarly, nitromethane gave one of the isomerides of 3-nitro-1:2-diphenyl-*n*-propyl cyanide (VIII; R = H), and nitroethane reacted with 4-bromo- α -cyanostilbene to give one of the isomerides of 3-nitro-2-phenyl-1-*p*-bromophenyl-*n*-butyl cyanide (IX), but all attempts to cause secondary nitro-paraffins to react with α -cyanostilbene were unsuccessful. Methyl 2-nitroethyl ether reacted with α -cyanostilbene in the presence of piperidine, but unexpectedly the product was acid-soluble, the methoxyl group having been replaced by a piperidine residue to give 3-nitro-4-piperidino-1:2-diphenyl-*n*-butyl cyanide (X).

In many of the above products (IV), (VII), (VIII), (IX), and (X) there is more than one asymmetric carbon atom, so that the compounds would be expected to be formed as mixtures of stereoisomerides. In these cases, only one isomer has been identified and no attempt has been made to isolate the other stereoisomerides: the yields recorded therefore do not necessarily indicate the extent of the reaction.

EXPERIMENTAL.

Microanalyses are by Mr. E. S. Morton. M. ps. are uncorrected.

3-Nitro-3-methyl-*n*-butyl Cyanide.—Aqueous potassium hydroxide (10 c.c. of 33%) was added to a solution of 2-nitropropane (261 g.) in alcohol (750 c.c.), which was then heated to boiling. Vinyl cyanide

(159 g.) was run into the stirred solution at such a rate that the mixture refluxed gently. After a further 1 hour's refluxing, the solution was cooled, made just acid to Congo-red by addition of 20% sulphuric acid, stirred with barium carbonate to remove excess of acid, and filtered. The filtered solution was fractionated to give the cyanide as a colourless oil (330 g.), b. p. 70°/0.09 mm. (Bruson, *loc. cit.*, gives b. p. 105—107°/1 mm.). (Found: C, 50.55; H, 7.0; N, 19.7. Calc. for $C_8H_{10}O_2N_2$: C, 50.7; H, 7.05; N, 19.7%). The iminoethyl ether hydrochloride, prepared by passing dry hydrogen chloride into an alcoholic solution of the cyanide below 20°, had m. p. 108° (Found: N, 11.75; Cl, 16.2. $C_8H_{10}O_2N_2 \cdot HCl$ requires N, 12.4; Cl, 15.8%). The amidine hydrochloride, prepared by the action of alcoholic ammonia on the iminoethyl ether hydrochloride, had m. p. 214° (Found: Cl, 18.4. $C_8H_{10}O_2N_3 \cdot HCl$ requires Cl, 18.15%).

1-Nitro-1-(2-cyanoethyl)cyclohexane.—Nitrocyclohexane (43 g.) was brought into reaction with vinyl cyanide (18 g.) as described for 2-nitropropane. Distillation gave the product as a pale yellow oil (24 g.), b. p. 98—108°/0.15 mm., which from light petroleum (b. p. 40—60°) gave colourless needles, m. p. 42° (Found: C, 59.9; H, 7.45; N, 15.25. $C_8H_{14}O_2N_2$ requires C, 59.35; H, 7.7; N, 15.4%).

3-Nitro-1:2-dimethyl-n-butyl Cyanide.—(a) 2-Nitropropane (6.65 g.), allyl cyanide (5.0 g.), ethyl alcohol (50 c.c.), and aqueous methyltriethylammonium hydroxide (2.7 c.c. of 37%) were refluxed for 20 hours. The product (9.45 g.; 80%), isolated as in the previous cases, was a colourless oil, b. p. 86—87°/0.24 mm. (Found: C, 54.5; H, 7.8; N, 17.55. $C_7H_{12}O_2N_2$ requires C, 53.85; H, 7.7; N, 17.95%).

(b) The above experiment was repeated using propenyl cyanide in place of allyl cyanide. A colourless oil, b. p. 86—87°/0.24 mm., was isolated in 55% yield (Found: N, 18.25%).

3-Nitro-1:2-dimethyl-n-butyl Cyanide.—2-Nitropropane (8.9 g.) was brought into reaction with isopropenyl cyanide (7.0 g.) as described above for propenyl cyanide. After isolation as before, the crude product was distilled, giving the cyanide (6.3 g.), b. p. 65°/0.08 mm., m. p. 51—53° (from alcohol) (Found: C, 53.5; H, 7.35; N, 17.7. $C_7H_{12}O_2N_2$ requires C, 53.85; H, 7.7; N, 17.95%).

3-Nitro-4-methoxy-4-phenyl-3-methyl-n-butyl Cyanide.—Aqueous sodium hydroxide (5 c.c. of 32%) and vinyl cyanide (37.5 g.) were added to a solution of methyl 2-nitro-1-phenylpropyl ether (48.5 g.; this series, Part III) in dioxan (100 c.c.), and the mixture was stirred at 20° for 18 hours. The solution was poured into water, acidified with hydrochloric acid, and extracted with chloroform. Fractionation of the extract gave the product as a colourless oil (50 g.), b. p. 163—167°/0.5 mm. (Found: C, 62.5; H, 6.3; N, 11.3. $C_{13}H_{16}O_3N_2$ requires C, 62.9; H, 6.45; N, 11.3%).

3-Nitro-5-n-butylsulphonyl-3-methyl-n-amyl Cyanide.—Vinyl cyanide (1.05 g.) and methyltriethylammonium hydroxide (0.75 c.c. of 37%) were added to a solution of 3-nitrodibutyl sulphone (4.2 g.; this series, Part XVII) in alcohol (20 c.c.), which was then refluxed for 3 hours, cooled, and poured into water (250 c.c.). The mixture was extracted with ether and the extract was washed with dilute aqueous sodium hydroxide, dried, and the solvent removed to yield the cyanide as a very viscous brown oil, which could not be distilled or induced to crystallise (Found: N, 9.9; S, 11.4. $C_{11}H_{20}O_4N_2S$ requires N, 10.5; S, 11.6%).

4-Nitro-n-butyl Cyanide.—A solution of sodium methoxide [from sodium (11.5 g.) and methyl alcohol (150 c.c.)] was slowly run into a stirred solution of nitroethane (38 g.) in methyl alcohol (75 c.c.) at 0—10°. Vinyl cyanide (27 g.) was slowly added at 20—25°; during the addition the white precipitate of the sodium salt of nitroethane dissolved. The mixture was then acidified with acetic acid (32 g.), the solvent removed under reduced pressure at 40°, and the residue diluted with sufficient water to dissolve the sodium acetate and extracted with ether. The extract was dried and fractionated to give the cyanide as a colourless oil (19 g.), b. p. 82—84°/0.25 mm. (Bruson, *loc. cit.*, gives b. p. 107—110°/2 mm.) (Found: N, 21.65. Calc. for $C_5H_9O_2N_2$: N, 21.85%).

3-Keto-n-butyl Cyanide.—3-Nitro-n-butyl cyanide (13 g.) was dissolved in alcohol (10 c.c.) and aqueous sodium hydroxide (8 c.c. of 32%) was added at 10—15°. The resulting solution was diluted with water (30 c.c.) and run into dilute sulphuric acid (70 c.c. of 30%) at 10—15°. After being stirred for a further 15 minutes the mixture was extracted with ether. The extract was dried and fractionated to give the ketone as a colourless oil, b. p. 98—102°/9 mm. The 2:4-dinitrophenylhydrazones formed orange leaflets, m. p. 146°, from 2-ethoxyethyl alcohol (Found: C, 47.55; H, 4.05; N, 25.25. $C_{11}H_{11}O_4N_2$ requires C, 47.65; H, 4.0; N, 25.25%).

3-Nitro-2-methyl-n-amyl Cyanide.—(a) 1-Nitropropane (8.9 g.) was added dropwise to a solution of potassium hydroxide (5.6 g.) in alcohol (20 c.c.), the temperature being kept below 10°. The solution was then stirred at 50° and a solution of allyl cyanide (6.7 g.) in alcohol (30 c.c.) was added dropwise. The solution was stirred at 50° for 18 hours, cooled, and neutralised by dropwise addition of 5N-sulphuric acid, followed by treatment with barium carbonate. The filtered solution was fractionated, giving 3-nitro-2-methyl-n-amyl cyanide as a colourless oil (12.5 g.; 80% yield), b. p. 76°/0.1 mm.

The oil (1 g.), dissolved in a solution of sodium hydroxide (0.5 g.) in alcohol (5 c.c.) and water (5 c.c.), was added dropwise to ice-cold sulphuric acid (10 c.c. of 30%) and the mixture poured into excess of a saturated solution of 2:4-dinitrophenylhydrazine in 2N-hydrochloric acid. After standing overnight the precipitate was collected and crystallised from alcohol, giving 3-keto-2-methyl-n-amyl cyanide 2:4-dinitrophenylhydrazone as orange needles, m. p. 103—104° (Found: C, 51.25; H, 4.7; N, 23.25. $C_{13}H_{15}O_4N_4$ requires C, 51.15; H, 4.9; N, 22.95%).

(b) The above experiment was repeated using propenyl cyanide in place of allyl cyanide. This gave the nitro-cyanide in 35% yield as a colourless oil, b. p. 74—75°/0.09 mm. Hydrolysis and reaction with 2:4-dinitrophenylhydrazine as before gave a product, m. p. 102—103°, identical with the 2:4-dinitrophenylhydrazone described in (a) above (Found: N, 22.95%).

3-Nitro-1:5-dicyanopentane.—A solution of sodium methoxide [from sodium (7.5 g.) and methyl alcohol (150 c.c.)] was added dropwise to a stirred solution of nitromethane (20 g.) in methyl alcohol (75 c.c.) at 0—10°, and vinyl cyanide (32 g.) added during 1 hour. The mixture was treated with acetic acid (20 g.), concentrated under reduced pressure, and the residue diluted with water (300 c.c.) and shaken with ether, which caused the separation of crystals. Repeated recrystallisation from alcohol (charcoal) gave colourless needles (4 g.) of 3-nitro-1:5-dicyanopentane, m. p. 63° (Found: C, 50.2; H, 5.4; N, 24.95. $C_5H_6O_2N_3$ requires C, 50.3; H, 5.4; N, 25.1%).

3-Nitro-1 : 5-dicyano-3-p-bromophenylpentane.—Methyltriethylammonium hydroxide (1 c.c. of 37%) was added to a solution of *p*-bromophenylnitromethane (4.3 g.) and vinyl cyanide (1.6 g.) in *tert*-butyl alcohol (50 c.c.). Next day, the precipitate was collected (1.7 g.) and recrystallised repeatedly from alcohol, giving the dicyanide as colourless needles, m. p. 138—139° (Found : N, 13.2; Br, 24.45. Calc. for $C_{12}H_{10}O_2N_4Br$: N, 13.05; Br, 24.85%).

3-Nitro-1 : 2-diphenyl-*n*-butyl Cyanide (III; R = Me).— α -Cyanostilbene (205 g.), nitroethane (75 g.), and diethylamine (100 c.c.) were heated at 35—40° until a clear solution resulted. On being kept overnight, the mixture solidified. After crystallisation, first from alcohol and then from 2-ethoxyethyl alcohol, the cyanide was obtained as colourless crystals (180 g.), m. p. 164—165° (Found : C, 72.3; H, 5.7; N, 10.1. $C_{17}H_{14}O_2N_2$ requires C, 72.85; H, 5.7; N, 10.0%).

3-Nitro-4-piperidino-1 : 2-diphenyl-*n*-butyl Cyanide (X).— α -Cyanostilbene (2.7 g.) was brought into reaction with methyl 2-nitroethyl ether (2.4 g.) in the presence of piperidine (1.75 g.) as described above for nitroethane. The product was collected, washed with methyl alcohol, and recrystallised repeatedly from acetone, giving colourless needles (2.9 g.), m. p. 171° (Found : C, 72.1; H, 6.65; N, 11.7. $C_{22}H_{20}O_2N_4$ requires C, 72.7; H, 6.9; N, 11.6%). The product was soluble in dilute acid and was reprecipitated unchanged by addition of sodium hydroxide.

3-Nitro-1 : 2-diphenyl-*n*-propyl Cyanide (VIII; R = H).— α -Cyanostilbene (38.5 g.), nitromethane (15 g.), and diethylamine (20 c.c.) were heated at 50° until a homogeneous solution resulted. After several days at 20°, the crystalline precipitate was collected, washed with ether, and recrystallised from alcohol, giving the cyanide as colourless prisms (5.5 g.), m. p. 94—96° (Found : N, 10.55. $C_{16}H_{14}O_2N_2$ requires N, 10.55%).

3-Nitro-2-phenyl-1-p-bromophenyl-*n*-butyl Cyanide (XIV).—Nitroethane (1.65 g.), 4-bromo- α -cyanostilbene (5.7 g.), Frost, *Annalen*, 1889, 250, 161) and piperidine (1.75 g.) were mixed and kept at 20° for 3 days. The semi-solid mass was then dissolved in hot methyl alcohol (10 c.c.) and allowed to cool. The crystalline product was collected (3.35 g.) and purified by repeated recrystallisation from alcohol, giving colourless crystals of the cyanide, m. p. 187—189° (Found : C, 56.65; H, 4.2; N, 8.05; Br, 21.75. $C_{17}H_{14}O_2N_2Br$ requires C, 56.8; H, 4.2; N, 7.8; Br, 22.3%).

[Received, January 23rd, 1947.]

294. Aliphatic Nitro-compounds. Part XV. Preparation of Heterocyclic Bases by Reduction of 3-Nitroalkyl Cyanides.*

By G. D. BUCKLEY and T. J. ELLIOTT.

Reduction of 3-nitro-3-methyl-*n*-butyl cyanide (I) with iron and hydrochloric acid gives a mixture of 5-amino-2 : 2-dimethylpyrroline *N*-oxide (II) [or its tautomeride (IIa)], with 5-amino-2 : 2-dimethylpyrrolidine (III) [or its tautomeride (IIIa)]. The structure of (III) is established by formation from it of mono- and di-benzoyl derivatives, and by its hydrolysis to 5 : 5-dimethyl-2-pyrrolidone (V) by water and Raney nickel. The structure of the *N*-oxide (II) follows from its reduction to (III) by zinc-dust distillation and to 2 : 2-dimethylpyrrolidine (IV) on catalytic hydrogenation. Similar reactions with analogues of (I) are described, and possible mechanisms are discussed.

WITH a view to the synthesis of 3-amino-3-methyl-*n*-butyl cyanide, 3-nitro-3-methyl-*n*-butyl cyanide (I) was reduced with iron and hydrochloric acid. Two products were obtained : (a) a crystalline solid, $C_6H_{13}ON_2$, m. p. 238° (17% yield), and (b) a crystalline volatile base, $C_6H_{12}N_2$, (30% yield), with a formula and equivalent weight in agreement with those of the expected amino-cyanide, but with properties which excluded this structure.

The base, $C_6H_{12}N_2$, with 0.5 mol. of benzoyl chloride in ether gave a weakly basic monobenzoyl derivative which formed a picrate and was precipitated unchanged from its hydrochloric acid solution by addition of ammonia.

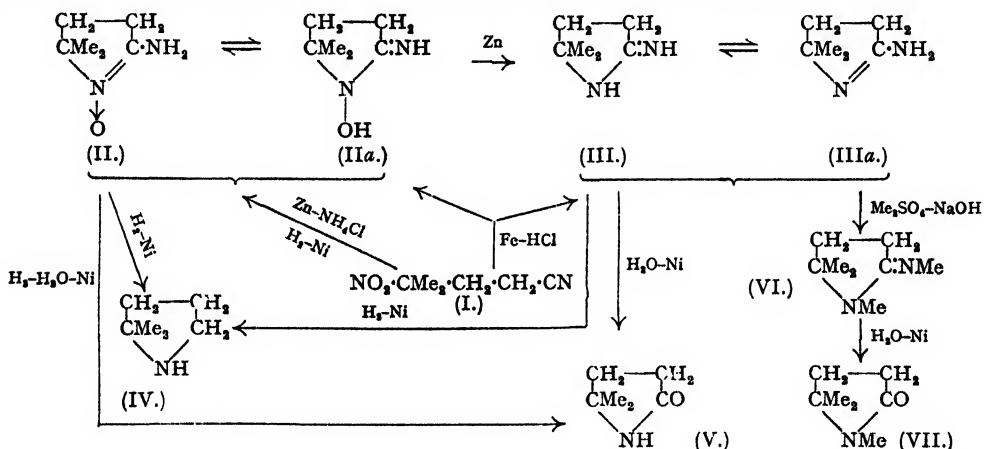

Benzoylation with excess of benzoyl chloride (Schotten-Baumann) gave both the monobenzoyl derivative and an acid-insoluble dibenzoyl derivative. This suggested that the base was the internal amidine 5-imino-2 : 2-dimethylpyrrolidine (III) [or 5-amino-2 : 2-dimethylpyrroline (IIIa)]. This was confirmed by the behaviour of the base on hydrolysis, reduction, and methylation. It was extremely resistant to acid or alkaline hydrolysis, but on boiling it with water in the presence of a little Raney nickel, ammonia was evolved and a crystalline, water-soluble solid $C_6H_{11}ON$, having the expected properties of 2 : 2-dimethyl-5-pyrrolidone (V), was formed. Reduction of the imine (III) with sodium and alcohol was difficult, but gave a small yield of 2 : 2-dimethylpyrrolidine (IV), also formed in good yield by catalytic reduction at 100°/100 atms. with Raney nickel under anhydrous conditions. Methylation of (III) with methyl sulphate and sodium hydroxide gave a dimethyl derivative, shown to be 5-methylimino-1 : 2 : 2-trimethylpyrrolidine (VI), by hydrolysis with water and Raney nickel to methylamine

* Patent application pending.

and 1 : 2 : 2-trimethyl-5-pyrrolidone (VII). The evidence in favour of the internal amidine structure (III) or (IIIa) is therefore conclusive.

Attention was then directed to the structure of the base $C_6H_{12}ON_2$ (above). This material was the main product when 3-nitro-3-methyl-*n*-butyl cyanide (I) was reduced with zinc dust and ammonium chloride under conditions which normally would be expected to reduce an aliphatic nitro-compound to the hydroxylamine, and was formed in 75% yield by reduction of (I) with hydrogen and Raney nickel at ordinary temperature and pressure. The base was weak; it gave a hydrochloride but would not react with benzoyl chloride, acetic anhydride, phenyl isocyanate, or *N*-nitro-*N'*-2 : 4-dinitrophenylurea. It contained two active hydrogen atoms (Zerewitinoff). Distillation with zinc dust gave the iminopyrrolidine (III), and reduction with sodium and alcohol gave a mixture of (III) and 2 : 2-dimethylpyrrolidine (IV). The latter was also formed by catalytic hydrogenation of the base $C_6H_{12}ON_2$ under anhydrous conditions at 100°/100 atms., but in the presence of water the pyrrolidone (V) was obtained in good yield, presumably by hydrolysis of the first-formed imine (III). Attempts to hydrolyse the base itself by boiling it with water and Raney nickel were unsuccessful.

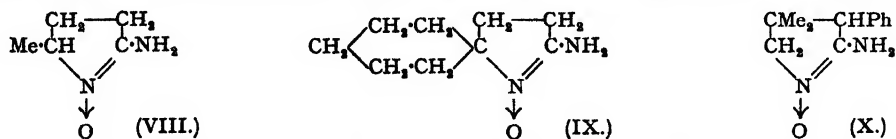

On this evidence the compound was formulated as 5-amino-2 : 2-dimethylpyrroline *N*-oxide (II) [or the tautomeric 5-imino-1-hydroxy-2 : 2-dimethylpyrrolidine (IIa)], and its formation is ascribed to cyclisation of the first-formed 3-hydroxylamino-3-methyl-*n*-butyl cyanide. A similar case has been reported by Bauer (*Ber.*, 1938, 71, 2226), who hydrogenated *o*-nitrostyryl cyanide over a palladium catalyst and obtained 2-aminoquinoline *N*-oxide in 60% yield.

In the reduction of the nitro-cyanide (I) with iron and hydrochloric acid, the iminopyrrolidine (III) might be formed either by reduction of the *N*-oxide (II) or by reduction of the nitro-cyanide to amino-cyanide, followed by cyclisation. Although difficult to prove conclusively, the former appears to be the more probable route; a careful search failed to reveal any amino-cyanide in the reduction products of (I), and it has been shown that the *N*-oxide (II) is, in fact, slowly reduced to the iminopyrrolidine (III) by iron and hydrochloric acid.

Attempts to reduce 3-nitro-3-methyl-*n*-butyl cyanide with platinum or palladium catalysts in the presence of mineral acids were unsuccessful, and use of stannous chloride and hydrochloric acid resulted in hydrolysis. It was concluded, therefore, that the preparation of 3-amino-3-methyl-*n*-butyl cyanide by reduction of the nitro-cyanide was impracticable.

Analogues of (I) were obtained, usually in good yield, by catalytic reduction of other 3-nitroalkyl cyanides. 3-Nitro-*n*-butyl cyanide gave 5-amino-2-methylpyrroline *N*-oxide (VIII), 1-nitro-1-(2-cyanoethyl)cyclohexane gave 5-amino-2 : 2-pentamethylenepyrroline *N*-oxide (IX),

and 3-nitro-1-phenyl-2 : 2-dimethyl-*n*-propyl cyanide gave 2-amino-3-phenyl-4 : 4-dimethylpyrroline *N*-oxide (X). Results of hydrogenations at 100 atms. were similar to those obtained

at atmospheric pressure. Raney nickel and palladised calcium carbonate appeared to be equally effective as catalysts, but Adams's platinum oxide gave inferior yields.

EXPERIMENTAL.

Analyses are by Mr. E. S. Morton. M. ps. are uncorrected. The nitro-cyanides were prepared by the methods described in Parts XIII and XIV of this series.

Reduction of 3-Nitro-3-methyl-n-butyl Cyanide.—(a) *With iron and hydrochloric acid.* Iron filings (30–60 mesh) (70 g.), water (150 c.c.), and hydrochloric acid (20 c.c. of 35%) were stirred together until the solution was no longer acid to Congo-red. The mixture was then heated to 100° and a solution of 3-nitro-3-methyl-n-butyl cyanide (47.5 g.) in alcohol (100 c.c.) was run in during 1 hour. The mixture was stirred and refluxed for 18 hours, cooled, and the filtered solution acidified to Congo-red with hydrochloric acid. The alcohol was distilled under reduced pressure, the residue diluted with sufficient water to dissolve the salts, and washed with ether. The aqueous solution was made strongly alkaline with potassium hydroxide and extracted repeatedly with ether (see later). The aqueous alkaline solution was then treated with solid potassium hydroxide and the precipitate collected and dissolved in a little water. Dilute hydrochloric acid was added until the solution was no longer alkaline to Clayton-yellow, and, after evaporation under reduced pressure, the product was isolated by extraction with absolute alcohol, evaporation of the extract and treatment with acetone giving 5-amino-2 : 2-dimethylpyrroline N-oxide (II) (8.0 g.) as a crystalline solid, which separated from alcohol-acetone in colourless plates, m. p. 238° (Found : C, 56.35; H, 9.45; N, 22.15. $C_6H_{12}ON_2$ requires C, 56.25; H, 9.4; N, 21.9%). The product was very soluble in water, chloroform, and alcohol, insoluble in ether, acetone, ethyl acetate, dioxan, and hydrocarbons. The hydrochloride had m. p. 173° (Found : Cl, 21.75. $C_6H_{12}ON_2 \cdot HCl$ requires Cl, 21.6%). The picrate, m. p. 160°, formed yellow needles from alcohol (Found : N, 20.0. $C_6H_{12}ON_2 \cdot C_6H_3O_7N_3$ requires N, 19.6%).

The ethereal extract was dried (KOH) and distilled, giving 5-imino-2 : 2-dimethylpyrrolidine (III) as colourless crystals (14.4 g.), b. p. 108–110°/15 mm., m. p. 73–74° [Found : *M* (by titration with 0.1N-hydrochloric acid to bromophenol-blue), 113.2. $C_6H_{12}N_2$ requires *M*, 112]. The picrate, m. p. 203–204°, formed yellow needles from alcohol (Found : N, 20.4. $C_6H_{12}N_2 \cdot C_6H_3O_7N_3$ requires N, 20.5%).

A solution of benzoyl chloride (0.6 g.) in dry ether (5 c.c.) was cautiously added to a solution of 5-imino-2 : 2-dimethylpyrrolidine (1 g.) in dry ether (5 c.c.). A vigorous reaction occurred, and after evaporation of the solvent the product was extracted with dilute aqueous ammonia and crystallised from 50% aqueous alcohol, giving the monobenzoyl derivative (0.6 g.) as colourless prisms, m. p. 98°, soluble in dilute hydrochloric acid and reprecipitated unchanged by addition of ammonia (Found : C, 72.0; H, 7.15; N, 12.65. $C_{12}H_{16}ON_2$ requires C, 72.2; H, 7.4; N, 12.95%).

Benzoyl chloride (6 g.) was added dropwise to a stirred and ice-cooled mixture of 5-imino-2 : 2-dimethylpyrrolidine (2 g.), sodium hydroxide (3.2 g.), and water (25 c.c.) at 10–15°. The mixture was stirred at 10–20° until the excess of benzoyl chloride had decomposed, and the precipitate was then collected, washed with water, and extracted with cold N-hydrochloric acid (50 c.c.). Treatment of the extract with aqueous ammonia precipitated a monobenzoyl derivative, identical with that described above. The acid-insoluble portion (3.2 g.) was repeatedly crystallised from acetone, giving colourless needles (0.3 g.), m. p. 179° (Found : C, 69.75; H, 5.65; N, 9.05%). This material was not further investigated. The acetone mother liquors were evaporated and the residue crystallised from alcohol, giving colourless needles of 5-benzimidazo-1-benzoyl-2 : 2-dimethylpyrrolidine, m. p. 133° (Found : C, 74.65; H, 6.6; N, 8.7. $C_{20}H_{26}O_2N_4$ requires C, 75.0; H, 6.25; N, 8.75%).

(b) *With zinc dust and ammonium chloride.* Zinc dust (25 g.) was added during 2½ hours to a vigorously stirred mixture of 3-nitro-3-methyl-n-butyl cyanide (20 g.), ammonium chloride (6 g.), and water (80 c.c.) at 10–15°. When reaction was complete the solution was filtered, neutralised with hydrochloric acid, evaporated under reduced pressure, and the residue extracted with absolute alcohol; the extract on dilution with dry ether gave the hydrochloride, m. p. 173°, of 5-amino-2 : 2-dimethylpyrroline N-oxide, from which the base, m. p. 238°, was obtained by basification.

(c) *Catalytically.* 3-Nitro-3-methyl-n-butyl cyanide (150 g.), dissolved in methyl alcohol (1500 c.c.), was shaken with Raney nickel and hydrogen at 20°/1 atm. until absorption of hydrogen ceased. The filtered solution was concentrated, finally by heating at 100°/20 mm., and the residue treated with acetone, giving 5-amino-2 : 2-dimethylpyrroline N-oxide. A second crop was obtained by concentrating the mother liquor and again treating the residue with acetone. The total yield was 101 g. (75%).

Reduction of 5-Amino-2 : 2-dimethylpyrroline N-Oxide.—(a) *Catalytically.* A solution of 5-amino-2 : 2-dimethylpyrroline N-oxide (10 g.) in anhydrous methanol (100 c.c.) was stirred with hydrogen and water and Raney nickel (1 g.) in an autoclave at 100°/100 atms. until absorption was complete, cooled, filtered from catalyst, and steam-distilled until free from volatile bases. The distillate was acidified with hydrochloric acid and evaporated to dryness. The hydrochloride was treated with a large excess of 40% aqueous potassium hydroxide, the base extracted with ether, the extract dried (KOH), and fractionated, giving 2 : 2-dimethylpyrrolidine (IV) (4.9 g.) as a colourless liquid, b. p. 105–106° (Found : *M* (by titration with 0.1N-hydrochloric acid to bromophenol-blue), 100.2. $C_6H_{12}N_2$ requires *M*, 99). The picrate, m. p. 190–191°, formed yellow needles from water (Found : N, 17.5. $C_6H_{12}N_2 \cdot C_6H_3O_7N_3$ requires N, 17.1%). The 2 : 4-dinitrophenylcarbonyl derivative (cf. McVeigh and Rose, *J.*, 1945, 621), m. p. 131°, formed long yellow needles from alcohol (Found : C, 50.65; H, 5.25; N, 18.2. $C_{11}H_{14}O_2N_4$ requires C, 50.65; H, 5.2; N, 18.2%).

(b) *With sodium and alcohol.* 5-Amino-2 : 2-dimethylpyrroline N-oxide (75 g.) was dissolved in absolute alcohol (2 l.) and treated rapidly at the boil with sodium (170 g.). When the sodium was completely dissolved, the solution was cooled and cautiously acidified to Congo-red with concentrated hydrochloric acid, filtered from salt and steam-distilled. The residual solution was diluted with an equal volume of 32% aqueous sodium hydroxide and extracted with ether. The extract, after drying

and distillation, yielded 5-imino-2 : 2-dimethylpyrrolidine (14.2 g.). The steam-distillate was acidified with hydrochloric acid and evaporated to dryness, leaving a hydrochloride, which, after basification and distillation, yielded 2 : 2-dimethylpyrrolidine (7.2 g.).

(c) *By distillation with zinc dust.* 5-Amino-2 : 2-dimethylpyrroline *N*-oxide (30 g.) was mixed thoroughly with zinc dust (30 g.) and heated, 20 g. at a time, in a distillation apparatus under 20 mm. The bath was heated to 280° and the temperature was then slowly raised to 320° and held at this until distillation ceased. The distillate was extracted with ether and the extract dried (KOH) and fractionated giving 5-imino-2 : 2-dimethylpyrrolidine (7 g.), b. p. 106°/15 mm.

(d) *With iron and hydrochloric acid.* 5-Amino-2 : 2-dimethylpyrroline *N*-oxide (20 g.) was reduced for 48 hours at 95–100° with iron (35 g.) and hydrochloric acid as described above for the reduction of the nitro-cyanide. Isolation as before gave 5-imino-2 : 2-dimethylpyrrolidine (7.9 g.), together with much unchanged starting materials.

Reduction of 5-Imino-2 : 2-dimethylpyrrolidine.—(a) *Catalytically.* The base (5 g.) was hydrogenated at 100°/100 atms. under anhydrous conditions as described above for 5-amino-2 : 2-dimethylpyrroline *N*-oxide. The resulting solution was filtered and fractionated, giving 2 : 2-dimethylpyrrolidine (1V) (3.8 g.); picrate, m. p. 190–191°.

(b) *With sodium and alcohol.* 5-Imino-2 : 2-dimethylpyrrolidine (7 g.) was reduced with sodium (50 g.) and absolute alcohol (600 c.c.) as described above for the pyrroline oxide. The product was worked up as before to give a small amount of 2 : 2-dimethylpyrrolidine, together with unchanged 5-imino-2 : 2-dimethylpyrrolidine (3.2 g.).

2 : 2-Dimethyl-5-pyrrolidone (V).—(a) A solution of 5-imino-2 : 2-dimethylpyrrolidine (3 g.) in water (30 c.c.) was stirred and refluxed for 3 hours with Raney nickel (0.1 g.); ammonia was evolved. The filtered solution was distilled, giving 2 : 2-dimethyl-5-pyrrolidone (2.1 g.) as colourless, hygroscopic crystals, m. p. 42°, b. p. 140°/20 mm. (Found : C, 63.4; H, 9.7; N, 12.15. $C_6H_{11}ON$ requires C, 63.7; H, 9.75; N, 12.4%). The hydrochloride had m. p. 150–152° (Found : Cl, 23.4. $C_6H_{11}ON \cdot HCl$ requires Cl, 23.75%).

(b) 5-Amino-2 : 2-dimethylpyrroline *N*-oxide (5 g.), dissolved in methyl alcohol (100 c.c.), was stirred with Raney nickel and hydrogen at 100°/100 atms. until absorption of hydrogen ceased. Distillation of the product gave 2 : 2-dimethyl-5-pyrrolidone (3.2 g.).

Methylation of 5-Imino-2 : 2-dimethylpyrrolidine.—Methyl sulphate (40 g.) was added dropwise to a stirred and cooled mixture of 5-imino-2 : 2-dimethylpyrrolidine (10 g.) and aqueous sodium hydroxide (80 c.c. of 16%) at 10–15°. The mixture was stirred at 10–20° until the excess of methyl sulphate had decomposed, and was then treated with an equal volume of 32% sodium hydroxide solution and extracted with ether. The extract was dried (KOH) and distilled, giving 5-methylimino-1 : 2 : 2-trimethylpyrrolidine (VI) (11 g.) as a colourless oil, b. p. 97–98°/18 mm. The picrate, m. p. 125°, formed yellow needles from water (Found : C, 46.2; H, 5.1; N, 19.25. $C_8H_{16}N_2 \cdot C_6H_5O_7N_3$ requires C, 45.55; H, 5.15; N, 19.0%).

1 : 2 : 2-Trimethyl-5-pyrrolidone (VII).—The base (above) (6.8 g.) in water (70 c.c.) was boiled with Raney nickel for 3 hours. An aqueous solution of the evolved gases was shown to be free from ammonia (no precipitate with Nessler's reagent), but, on boiling with *N*-nitro-*N'*-2 : 4-dinitrophenylurea, gave *N*-2 : 4-dinitrophenyl-*N'*-methylurea, m. p. and mixed m. p. with an authentic specimen, 204° (cf. McVeigh and Rose, *loc. cit.*). The aqueous residue was filtered from catalyst and distilled, giving 1 : 2 : 2-trimethyl-5-pyrrolidone (VII) (4.9 g.) as a colourless oil, b. p. 130°/60 mm. (Found : C, 66.2; H, 10.2; N, 10.95. $C_7H_{13}ON$ requires C, 66.1; H, 10.25; N, 11.05%).

5-Amino-2-methylpyrroline *N*-Oxide (VIII).—3-Nitro-*n*-butyl cyanide (32 g.) in methyl alcohol (400 c.c.) was hydrogenated in the presence of Raney nickel at 20°/1 atm. The filtered solution was concentrated and the residue was stirred with acetone and the solid collected (5 g.). Crystallisation from chloroform-acetone gave colourless, hygroscopic needles, m. p. 206° (Found : C, 52.65; H, 8.4; N, 24.3. $C_6H_{10}ON_2$ requires C, 52.65; H, 8.75; N, 24.55%).

5-Amino-2 : 2-pentamethylenepyrroline *N*-Oxide (IX).—1-Nitro-1-(2-cyanoethyl)cyclohexane (21 g.) was hydrogenated and the product (8 g.) isolated as described above. Crystallisation from acetone-alcohol gave the base as colourless leaflets, m. p. 206° (Found : N, 16.4. $C_8H_{14}ON_2$ requires N, 16.65%). The hydrochloride had m. p. 200° (Found : Cl, 17.45. $C_8H_{14}ON_2 \cdot HCl$ requires Cl, 17.3%).

2-Amino-3-phenyl-4 : 4-dimethylpyrroline *N*-Oxide (X).—3-Nitro-1-phenyl-2 : 2-dimethyl-*n*-propyl cyanide (5 g.), dissolved in methyl alcohol (50 c.c.), was shaken with hydrogen and 5% palladised calcium carbonate (1 g.) until absorption of hydrogen was complete. After filtration from catalyst, the solution was evaporated on the steam-bath and the residue was treated with acetone and collected (3 g.); crystallisation from acetone-alcohol gave colourless granules, m. p. 189–190° (Found : N, 13.7. $C_{12}H_{16}ON_2$ requires N, 13.7%).

HEXAGON HOUSE, BLACKLEY, MANCHESTER, 9.

[Received, January 23rd, 1947.]

295. Aliphatic Nitro-compounds. Part XVI. Condensation of Hydroxymethyldialkylamines with Nitro-paraffins.

By A. LAMBERT and J. D. ROSE.

Hydroxymethyl derivatives of secondary amines and nitromethane or nitroethane yield, on heating, only nitro-diamines of type II ($R = H$ or Me). 1-Nitropropane gives chiefly the nitro-amine (III; $R = Et$) and a little nitro-diamine (I; $R = Et$). Nitro-amines (III; $R = Me$) are prepared from nitroethane and hydroxymethyldialkylamine by carrying out the

reaction for a short time at ordinary temperature. Reductions of the nitro-diamines and nitro-amines to triamines and diamines respectively are described.

IN connection with other synthetic work in progress in these laboratories, amines of the types (II) and (IV) were required, and it appeared probable that the simplest and most direct method of synthesis would be from nitro-paraffins and hydroxymethyl derivatives of secondary amines, followed by hydrogenation of the nitro-amine so formed.

Substances of type (I) ($R = H$ or Me) were prepared first by Henry (*Bull. Soc. chim.*, 1896, 15, 1225; *Ber.*, 1905, 38, 2027) from nitromethane and nitroethane with *N*-hydroxymethylpiperidine. Despite this, de Mauney (*Bull. Soc. chim.*, 1937, 4, 1451, 1460), as a result of experiments on the condensation of hydroxymethyl secondary amines with nitromethane, 1-nitropropane, 1-nitrobutane, and 1-nitro-octane, stated that the reaction product from primary nitro-paraffin always contained one free α -hydrogen atom, *i.e.*, nitromethane combines with two and other primary nitro-paraffins with only one mol. of hydroxymethylamine. As was shown by Zief and Mason (*J. Org. Chem.*, 1943, 8, 1), nitroethane is an exception to this rule as it condenses with *N*-hydroxymethylpiperidine (Henry, *loc. cit.*) and with *N*-hydroxymethylmorpholine to give compounds of type (I) ($R = Me$). Furthermore, although 1-nitropropane reacts with *N*-hydroxymethyldiethylamine to give mainly 2-nitro-1-diethylaminobutane (III; $R = R' = Et$), we have also obtained small yields of the bis-condensate, 2-nitro-1 : 3-bis(diethylamino)-2-ethylpropane, from this reaction.

The formation of amines of the type (III) ($R = Me$) from nitroethane is a matter of some difficulty. Attempts to degrade the bis-adducts of type (I) from nitroethane to mono-adducts of type (III) by alkaline reagents were uniformly unsuccessful, although this method is applicable to the degradation of, *e.g.*, tris(hydroxymethyl)nitromethane to 2-nitropropane-1 : 3-diol. Since 2-nitro-2-methylpropane-1 : 3-diol condenses with, *e.g.*, hydroxymethylpiperidine to give the nitro-diamine in good yield, an attempt was made to effect a similar reaction with 2-nitro-*n*-propyl alcohol. Disproportionation occurred, the only product isolated being 2-nitro-1 : 3-dipiperidino-2-methylpropane, formed by fission of the nitro-alcohol to nitroethane and formaldehyde, followed by recombination in the appropriate proportions. Similarly, 2-nitroethyl alcohol and piperidine yielded only 2-nitro-1 : 3-dipiperidinopropane, and 2-nitroisopropyl alcohol (from nitromethane and acetaldehyde), on treatment with hydroxymethylpiperidine, gave acetaldehyde and 2-nitro-1 : 3-dipiperidinopropane.

Finally, the nitro-monoamines of type (III) were obtained by allowing equimolecular proportions of the nitro-paraffin and the hydroxymethylamine to interact at room temperature. In this way, 2-nitro-1-diethylaminopropane was obtained in 70% yield from nitroethane and hydroxymethyldiethylamine, and 2-nitro-1-piperidinopropane was formed from nitroethane and hydroxymethylpiperidine. Although the nitro-amines were unstable and could not be obtained pure, and precipitated nitro-diamine on storage, reduction of the freshly prepared crude products gave the diamines (IV).

EXPERIMENTAL.

Analyses are by Mr. E. S. Morton. All m. ps. are uncorrected.

2-Nitro-1 : 3-dipiperidino-2-methylpropane.—(a) This was prepared from hydroxymethylpiperidine and nitroethane according to Henry (*loc. cit.*); white needles from alcohol, m. p. 102°. Henry (*loc. cit.*) gives m. p. 98—99° (Found: C, 62.3; H, 9.7; N, 15.3. Calc. for $C_{14}H_{24}O_2N_4$: C, 62.8; H, 10.0; N, 15.6%).

(b) A mixture of 2-nitro-2-methylpropane-1 : 3-diol (Vanderbilt and Hass; *Ind. Eng. Chem.*, 1940, 32, 34; 136 g.) and piperidine (170 g.) in alcohol (300 c.c.) was refluxed for 3 hours. After cooling, the crystals were collected, washed with a little alcohol, and dried, and had m. p. 102° alone and in admixture with a sample prepared as (a) above. Yield, 172 g.

2-Nitro-1 : 3-bis(diethylamino)-2-methylpropane.—Formaldehyde (40%; 75 c.c.) was treated with diethylamine (74 g.) in water (75 c.c.) at 0°, and to the mixture nitroethane (37 g.) was added with stirring at room temperature. After 16 hours' stirring the supernatant oil was isolated with ether, dried (K_2CO_3), and fractionated to give 2-nitro-1 : 3-bis(diethylamino)-2-methylpropane as an almost colourless liquid, b. p. 94—96°/0.2 mm. (Found: C, 58.8; H, 10.7; N, 16.6. $C_{18}H_{32}O_2N_4$ requires C, 58.8; H, 11.0; N, 17.1%). This diamine was unchanged by treatment with 1 mol. of sodium methoxide in methyl alcohol at room temperature. Catalytic hydrogenation with Raney nickel and hydrogen caused decomposition to low boiling products among which bis(diethylamino)methane was recognised.

2-Amino-1 : 3-bis(diethylamino)-2-methylpropane.—Crude 2-nitro-1 : 3-bis(diethylamino)-2-methylpropane, prepared as above (not distilled; total product after concentration of ethereal solution) from nitroethane (37 g.), was added dropwise with stirring to an ice-cold solution of stannous chloride (327 g.) in concentrated hydrochloric acid (500 c.c.). After 1 hours' stirring, excess of 30% aqueous sodium hydroxide was added and the product isolated with ether, dried (K_2CO_3), and fractionated. The fraction, b. p. 63–67°/0.2 mm., was dried over sodium and redistilled, giving the *amine* as a colourless oil, b. p. 60°/0.1 mm. (Found : N, 19.6. $C_{13}H_{29}N_3$ requires N, 19.5%).

2-Amino-1 : 3-bis(diethylamino)-2-ethylpropane.—A solution of diethylamine (73 g.) in water (75 c.c.) was added at 0° to formaldehyde (40%; 75 c.c.) and 1-nitropropane (45 g.) then added and the mixture stirred at room temperature for 20 hours. The upper layer was isolated with ether and distilled, giving chiefly 2-nitro-1-diethylaminobutane, b. p. 70°/0.4 mm. (cf. de Mauney, *loc. cit.*), and crude 2-nitro-1 : 3-bis(diethylamino)-2-ethylpropane (18 g.), b. p. 108°/0.2 mm., with slight decomposition (Found : N, 15.3. $C_{13}H_{29}O_2N_3$ requires N, 16.2%). This latter was reduced as described above for the lower homologue, with stannous chloride (60 g.) and hydrochloric acid (100 c.c.) at 0°, giving 2-amino-1 : 3-bis(diethylamino)-2-ethylpropane (5 g.) as a colourless oil, b. p. 112–114°/10 mm. (Found : C, 67.7; H, 12.8; N, 17.8. $C_{13}H_{31}N_3$ requires C, 68.1; H, 13.5; N, 18.3%). The *triplicate* formed yellow prisms from water, m. p. 162° (Found : C, 40.6; H, 4.4; N, 17.8. $C_{13}H_{31}N_3 \cdot 3C_2H_5O_7N_3$ requires C, 40.6; H, 4.4; N, 18.3%).

2-Nitro-1-diethylaminopropane.—Formaldehyde (40%; 8.1 c.c.) and diethylamine (7.3 g.) in water (10 c.c.) were mixed at 0° and nitroethane (7.5 g.) was added slowly with cooling. The mixture was kept at room temperature for 4 hours, extracted with ether, and the ethereal extract dried and distilled. 2-Nitro-1-diethylaminopropane was obtained as a pale yellow oil (11 g.), b. p. 83.5°/11 mm. (Found : C, 52.6; H, 10.1; N, 17.3. $C_7H_{15}O_2N_2$ requires C, 52.5; H, 10.0; N, 17.5%), which decomposed slowly on keeping.

2-Amino-1-diethylaminopropane.—The nitro-amine (above) was reduced in methyl-alcoholic solution with Raney nickel and hydrogen at 70 atmospheres (initial pressure) and room temperature. Fractionation of the filtered solution gave 2-amino-1-diethylaminopropane, b. p. 148–149°/772 mm., in 47% yield [Found : equiv. (by titration), 66.9. $C_8H_{18}N_2$ requires equiv., 65].

2-Amino-1-piperidinopropane.—Formaldehyde (87%; 81 c.c.), piperidine (85 g.), water (85 c.c.), and nitroethane (75 g.) were brought into reaction as described above for the diethylamino-analogue. 2-Nitro-1-piperidinopropane was obtained as an oil (142 g.), b. p. 99–104°/7 mm. (slight decomp.), and could not be obtained analytically pure. On keeping, decomposition occurred and 2-nitro-1 : 3-dipiperidino-2-methylpropane was precipitated. Reduction of the freshly prepared material (128 g.) with Raney nickel and hydrogen at 60 atms. and 40° gave 2-amino-1-piperidinopropane as a colourless oil (54 g.), b. p. 92–93°/15 mm. (Found : equiv. by titration), 71.4. Calc. for $C_8H_{18}N_2$: equiv., 71). Wenker (*J. Amer. Chem. Soc.*, 1938, 60, 158), who prepared this compound by amination of 2-chloro-1-piperidinopropane, gives b. p. 193–194°/760 mm.).

Reaction of 2-Nitroethyl Alcohol with Piperidine.—2-Nitroethyl alcohol (10 g.), piperidine (20 c.c.), and dioxan (20 c.c.) were refluxed for 20 minutes and poured into water. The product was mainly 2-nitro-1 : 3-dipiperidinopropane, m. p. 93–94°, undepressed by admixture with an authentic specimen prepared from nitromethane and hydroxymethylpiperidine (Henry, *loc. cit.*).

Reaction of 2-Nitro-*n*-propyl Alcohol with Piperidine.—2-Nitro-*n*-propyl alcohol (21 g.) and piperidine (17 g.) were mixed; there was considerable heat evolution and the mixture was warmed on the steam-bath for one hour. On cooling, the dark liquor deposited crystals, which were collected and recrystallised from alcohol, giving 2-nitro-1 : 3-dipiperidino-2-methylpropane, m. p. 104° alone and in admixture with an authentic specimen.

Reaction of 2-Nitroisopropyl Alcohol with Piperidine and Formaldehyde.—2-Nitroisopropyl alcohol (10.5 g.) and piperidine (17.0 g.) were mixed and cooled, and formaldehyde (15 c.c.) was added. A pronounced smell of acetaldehyde became apparent and a crystalline solid separated. Recrystallised from alcohol, this gave 2-nitro-1 : 3-dipiperidinopropane, m. p. 93–94° alone and in admixture with an authentic specimen.

2 : 2'-Dipiperidinoisopropylamine.—2-Nitro-1 : 3-dipiperidinopropane (200 g.) in methyl alcohol (750 c.c.) was reduced with Raney nickel and hydrogen at 130 atms. (initial pressure) and 50°. Distillation of the filtered solution yielded 2 : 2'-dipiperidinoisopropylamine, b. p. 152–154°/11 mm. Yield, 124 g. (70%) (Found : C, 68.6; H, 11.9; N, 18.4. $C_{13}H_{27}N_3$ requires C, 69.3; H, 12.0; N, 18.6%). The *trihydrochloride* formed pearly plates from aqueous alcohol, m. p. 260° (Found : Cl, 31.7. $C_{13}H_{27}N_3 \cdot 3HCl$ requires Cl, 31.8%).

2 : 2'-Dipiperidinoisopropylurea.—The amine (8 g.), suspended in boiling water (100 c.c.), was treated cautiously with nitrourea; 11 g. (3 mols.) were necessary to give a clear solution. The filtered solution was treated with an excess of 10*N*-sodium hydroxide; the precipitated oil solidified immediately and was recrystallised from acetone. The *urea* had m. p. 86° (Found : C, 62.3; H, 10.3. $C_{14}H_{28}ON_4$ requires C, 62.6; H, 10.4%). The *dimethiodide*, from aqueous alcohol, had m. p. 257° (decomp.) (Found : N, 9.6; I, 45.7. $C_{14}H_{34}ON_4I_2$ requires N, 10.1; I, 46.0%).

The authors wish to acknowledge the interest and advice of Mr. C. Paine and Dr. H. A. Piggott in this work.

296. Aliphatic Nitro-compounds. Part XVII. Reaction of Nitro-paraffins with Unsaturated Sulphones.*

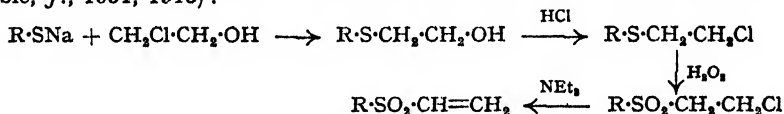

By G. D. BUCKLEY, (MRS.) J. L. CHARLISH, and J. D. ROSE.

Nitro-paraffins react with vinyl sulphones in the presence of alkaline catalysts to yield 3-nitroalkyl sulphones. The use of small amounts of catalyst results in the replacement of all the α -hydrogen atoms of the nitro-paraffin to give nitro-monosulphones from secondary nitro-paraffins, nitro-disulphones from primary nitro-paraffins, and nitro-trisulphones from nitromethane. The use of sufficient alkali to convert the whole of the nitro-paraffin into its salt results in the formation of mainly mononitro-sulphones from primary nitro-paraffins. 2-Halogenoethyl sulphones with an equivalent of alkali may be used in place of vinyl sulphones. Divinyl sulphone reacts in a similar manner: with secondary nitro-paraffins it gives 3:3'-dinitrodialkyl sulphones, but with primary nitro-paraffins the products are polymeric. Catalytic reduction of the nitro-sulphones affords the corresponding amino-sulphones, and their alkali metal salts give 3-keto-sulphones on treatment with mineral acids.

A convenient synthesis of vinyl sulphones is described.

PREVIOUS authors have described the addition of primary and secondary nitro-paraffins to $\alpha\beta$ -unsaturated nitro-compounds (this series, Part VIII), cyanides (Bruson and Riener, *J. Amer. Chem. Soc.*, 1943, 65, 23), and ketones and esters (Kohler, *J. Amer. Chem. Soc.*, 1916, 38, 889; Sonn, *Ber.*, 1935, 68, 148; Michael, *Ber.*, 1896, 29, 1794), but no attempt to cause them to react with vinyl sulphones appears to have been recorded.

Although divinyl sulphone is a well-known compound, the simple monovinyl sulphones appear to be described only in the patent literature (B.P. 442,524, I.G. Farbenindustrie). Since the method described seemed unsuitable for use on the laboratory scale, the monovinyl sulphones were prepared by the following route based on the usual synthesis of divinyl sulphone (Alexander and McCombie, *J.*, 1931, 1913):

This method gave *methyl*, *n-butyl*, *isobutyl*, and *p-tolyl* vinyl sulphones in satisfactory yield.

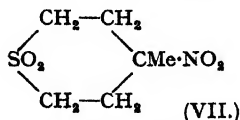

Nitroethane reacted readily with two molecules of *n-butyl* vinyl sulphone in presence of a small amount of potassium hydroxide to give a 75% yield of 3-nitro-1:5-di-(*n-butylsulphonyl*)-3-methylpentane (I; R = Me, R' = Bu) which was reduced catalytically to the corresponding amine. In presence of one equivalent of sodium hydroxide, nitroethane reacted with one molecule of *n-butyl* vinyl sulphone to give 3-nitrodibutyl sulphone (II; R = Me) in 45% yield, together with a 13% yield of the dinitrosulphone (I; R = Me, R' = Bu). It was not possible to suppress completely the formation of the dinitrosulphone even by the use of a large excess of alkali. 3-Nitrodibutyl sulphone was isolated as an oil by acidification of the alkaline solution with acetic or carbonic acids, but acidification with mineral acids precipitated 3-ketodibutyl sulphone (III; R = Me), formed by a Nef hydrolysis (*Annalen*, 1894, 280, 263), which appears to be unusually facile in the case of γ -nitro-sulphones. The nitro-sulphone could not be purified by distillation or crystallisation, but was reduced catalytically to the easily characterised 3-aminodibutyl sulphone (*hydrochloride*).

Similarly, 1-nitropropane reacted with *n-butyl* vinyl sulphone to give 3-nitro-1:5-di-(*n-butylsulphonyl*)-3-ethylpentane (I; R = Et, R' = Bu), *n-butyl* 3-nitroamyl sulphone (II; R = Et), and *n-butyl* 3-ketoamyl sulphone (III; R = Et). Reaction of the sodium salt of *n-butyl* 3-nitroamyl sulphone with aqueous bromine gave *n-butyl* 3-bromo-3-nitroamyl sulphone. Interaction of nitromethane and methyl vinyl sulphone in presence of a little potassium hydroxide gave a 50% yield of *tris*-(2-methylsulphonylethyl)nitromethane (IV), which was reduced catalytically to *tris*-(2-methylsulphonylethyl)methylamine. *p*-Bromophenylnitromethane with methyl vinyl sulphone and a little methyltriethylammonium hydroxide gave *methyl* 3-nitro-3-*p-bromophenylpropyl* sulphone (V; R = Me) in 50% yield, and the sodium salt of

* Patent application pending.

p-bromophenylnitromethane reacted with isobutyl vinyl sulphone to give isobutyl 3-nitro-3-*p*-bromophenylpropyl sulphone (V; R = CH₂·CHMe₂) in 30% yield. 1- and 2-Nitropropane with *p*-tolyl vinyl sulphone gave respectively 3-nitro-1:5-di-*p*-tolylsulphonyl-3-ethylpentane (I; R = Et, R' = *p*-MeC₆H₄) and 2-nitro-4-*p*-tolylsulphonyl-2-methylbutane (VI).

The behaviour of divinyl sulphone was next examined. It was hoped that interaction of equimolecular proportions of nitroethane and divinyl sulphone would yield the cyclic sulphone (VII), but although a variety of conditions were tried the only products isolated were polymeric, presumably of type (VIII). The expected cyclisation is apparently hindered by steric factors. Divinyl sulphone reacted normally with two molecules of 2-nitropropane to give 3:3'-dinitro-3:3'-dimethyldibutyl sulphone (IX) which, on catalytic reduction, gave 3:3'-diamino-3:3'-dimethyldibutyl sulphone.

Experiments with 2-chloroethyl *n*-butyl sulphone showed that 2-halogenoethyl sulphones with an equivalent of sodium hydroxide could be used instead of vinyl sulphones, but the yields were lower, e.g., 1-nitropropane reacted with 2-chloroethyl *n*-butyl sulphone to give 8% of 3-nitro-1:5-di-(*n*-butylsulphonyl)-3-ethylpentane (I; R = Et, R' = Bu) and 32% of *n*-butyl 3-nitroamyl sulphone (II; R = Et).

EXPERIMENTAL

Analyses are by Mr. E. S. Morton. All m. ps. are uncorrected.

Preparation of Alkyl Vinyl Sulphones.

Methyl Vinyl Sulphone.—Hydrogen peroxide (300 g. of 30%) was added dropwise to a solution of methyl 2-chloroethyl sulphide (135 g.) (*Org. Synth.*, Coll. Vol. 2, 136) in acetic acid (300 c.c.) at such a rate that the solution refluxed gently without external heating. After a further 3 hours' heating on the steam-bath, the solvents were removed by distillation under reduced pressure. The viscous residue, consisting essentially of methyl 2-chloroethyl sulphone, was added during 1 hour to a stirred solution of triethylamine (175 c.c.) in anhydrous ether (320 c.c.) and the mixture was stirred for a further 18 hours. The ethereal solution was decanted from the dark mass of triethylamine hydrochloride which was then extracted with dry acetone. The ether and acetone solutions were combined and fractionated to give methyl vinyl sulphone as a colourless oil (81 g.), b. p. 115–117°/19 mm. (Found: S, 29.8. C₃H₆O₂S requires S, 30.2%).

***n*-Butyl Vinyl Sulphone.**—2-Chloroethyl *n*-butyl sulphone was prepared by oxidation of the corresponding sulphide according to Whitner and Reid (*J. Amer. Chem. Soc.*, 1921, **43**, 637). The crude sulphone (158 g.) was added during 1 hour to a stirred solution of triethylamine (135 c.c.) in ether (250 c.c.) and the mixture was stirred for a further 18 hours. The solution was then filtered from triethylamine hydrochloride and distilled to give *n*-butyl vinyl sulphone as a colourless oil (104 g.), b. p. 135°/15 mm. (Found: S, 21.3. C₆H₁₂O₂S requires S, 21.6%).

isobutyl Vinyl Sulphone.—Ethylene chlorohydrin (99 g. of 30%) was added to a suspension of isobutylthiol (37 g.) in aqueous sodium hydroxide (115 g. of 15%) and refluxed for 1 hour. The mixture was then freed from volatile impurities by steam distillation and, after cooling, the residual oil, consisting of crude 2-hydroxyethyl isobutyl sulphide (40 g.), was separated, mixed with concentrated hydrochloric acid (60 c.c.) and refluxed for 4 hours. After cooling, the oily product was separated, dried (CaCl₂), and distilled, giving 2-chloroethyl isobutyl sulphide as a vesicant oil (39 g.), b. p. 84–85°/25 mm. (Found: Cl, 23.1. C₆H₁₂ClS requires Cl, 23.3%). The chloroethyl sulphide (38 g.) was oxidised to 2-chloroethyl isobutyl sulphone and this was converted into the vinyl sulphone as described above for the isomer. isobutyl vinyl sulphone was obtained as a colourless oil (22 g.), b. p. 132–133°/19 mm. Found: S, 21.8. C₆H₁₂O₂S requires S, 21.6%).

***p*-Tolyl Vinyl Sulphone.**—Hydrogen peroxide (145 g. of 30%) was added slowly to a boiling solution of *p*-tolyl 2-chloroethyl sulphide (36 g.) (Kohn and Fromm, *Ber.*, 1921, **54**, 322) in acetic acid (105 c.c.) and the mixture was refluxed for 2 hours. Water and acetic acid were removed under reduced pressure, and the residual crude *p*-tolyl 2-chloroethyl sulphone (42 g.) was dissolved in dry ether (80 c.c.) and added cautiously to a solution of triethylamine (40 c.c.) in dry ether (80 c.c.). Separation of triethylamine hydrochloride began at once, and, after standing overnight, the solution was filtered and evaporated to dryness. The residue was washed with cold water, giving a white, crystalline solid (25 g.) which, after crystallisation from alcohol, gave *p*-tolyl vinyl sulphone as white needles, m. p. 66° (I.G. Farbenindustrie, *loc. cit.*, give m. p. 65–66°).

Reaction with Nitro-paraffins.

3-Nitro-1:5-di-(*n*-butylsulphonyl)-3-methylpentane.—Aqueous potassium hydroxide (1 c.c. of 33%) was added to a solution of nitroethane (3.5 g.) and *n*-butyl vinyl sulphone (15 g.) in alcohol (40 c.c.) and refluxed for 16 hours. After cooling, the precipitate was collected (13.25 g.) and crystallised from

alcohol, giving 3-nitro-1:5-di-(*n*-butylsulphonyl)-3-methylpentane (I; R = Me, R' = Bu) as colourless needles, m. p. 105° (Found: N, 4.1; S, 17.1. $C_{14}H_{28}O_6NS_2$ requires N, 3.8; S, 17.25%).

3-Nitrodibutyl Sulphone.—Aqueous sodium hydroxide (20 c.c. of 32%) was slowly added to a stirred and ice-cooled mixture of nitroethane (15 g.) and water (80 c.c.). When a homogeneous solution had formed, *n*-butyl vinyl sulphone (30 g.) was added and the mixture stirred at 20° for 3 hours. The solid precipitate (10 g.) was collected and washed with water; it was identical with the 3-nitro-1:5-di-(*n*-butylsulphonyl)-3-methylpentane described above. The alkaline filtrate was washed with ether to remove impurities, acidified with acetic acid (13 c.c.), and extracted with ether. The ethereal extract was dried and evaporated, leaving 3-nitrodibutyl sulphone (II; R = Me) as a pale yellow oil (21 g.) which could not be crystallised and decomposed on attempted distillation. With nitrous acid it gave a blue colouration, indicating the presence of a secondary nitro-group.

3-Aminodibutyl Sulphone.—Crude 3-nitrodibutyl sulphone (23 g.) in methyl alcohol (200 c.c.) was shaken with Raney nickel and hydrogen at 20°/1 atm. until absorption ceased. The filtered solution was distilled, giving 3-aminodibutyl sulphone (8.6 g.) as a colourless, feebly basic oil, b. p. 122°/0.5 mm. The hydrochloride formed colourless granules, m. p. 145° (Found: Cl, 15.8. $C_8H_{18}O_2NS.HCl$ requires Cl, 15.55%). The phenylurea formed colourless granules from benzene, m. p. 107° (Found: N, 9.15; S, 10.1. $C_{11}H_{20}O_2N_2S$ requires N, 9.0; S, 10.25%).

3-Ketodibutyl Sulphone (III; R = Me).—A solution of the sodium salt of 3-nitrodibutyl sulphone, prepared from nitroethane (3.75 g.) and *n*-butyl vinyl sulphone (7.5 g.) as described above, was run into a stirred solution of sulphuric acid (6.5 c.c.) in water (30 c.c.) during 30 minutes, the temperature being kept at 10–15°. The crystalline precipitate was collected (3.8 g.) and recrystallised from a little methyl alcohol at –20°, giving the ketone as colourless plates, m. p. 59° (Found: S, 16.6. $C_8H_{16}O_3S$ requires S, 16.65%). The 2:4-dinitrophenylhydrazones, m. p. 147°, formed yellow needles from alcohol (Found: N, 14.85; S, 8.6. $C_{14}H_{20}O_6N_4S$ requires N, 15.05; S, 8.6%).

3-Amino-1:5-di-(*n*-butylsulphonyl)-3-methylpentane.—3-Nitro-1:5-di-(*n*-butylsulphonyl)-3-methylpentane (5.8 g.) was suspended in 2-ethoxyethyl alcohol (100 c.c.) and shaken with Raney nickel and hydrogen at 20°/1 atm. until absorption ceased; during the reaction the solid gradually passed into solution. The filtered solution was concentrated under reduced pressure and the residue crystallised from benzene, giving colourless crystals of the amine, m. p. 116° (Found: N, 4.1; S, 19.1. $C_{14}H_{28}O_6NS_2$ requires N, 4.15; S, 18.8%). The acetyl derivative formed colourless needles from water, m. p. 164° (Found: S, 16.35. $C_{14}H_{28}O_6NS_2$ requires S, 16.7%).

3-Nitro-1:5-di-(*n*-butylsulphonyl)-3-ethylpentane and *n*-Butyl 3-Nitroamyl Sulphone.—(a) From *n*-butyl vinyl sulphone. Aqueous sodium hydroxide (5 c.c. of 32%) was slowly added to a stirred and ice-cooled mixture of 1-nitropropane (4.5 g.) and water (20 c.c.). When the oil had completely dissolved, *n*-butyl vinyl sulphone (7.5 g.) was added and the mixture was stirred at 50° for 3 hours. After cooling, the solid product was collected (1.65 g.). Crystallisation from alcohol gave 3-nitro-1:5-di-(*n*-butylsulphonyl)-3-ethylpentane (I; R = Et, R' = Bu) as colourless needles, m. p. 104° (Found: N, 3.9; S, 16.8. $C_{15}H_{31}O_6NS_2$ requires N, 3.65; S, 16.6%). The alkaline filtrate was washed with ether, acidified with acetic acid (3.5 c.c.), extracted with ether, and the dried extract concentrated, giving *n*-butyl 3-nitroamyl sulphone (II; R = Et) as a pale yellow oil (6 g.) which could not be purified by crystallisation or distillation. With nitrous acid it gave a positive test for a secondary nitro-group.

(b) From 2-chloroethyl *n*-butyl sulphone. Aqueous sodium hydroxide (12 c.c. of 32%) was added slowly to an ice-cold solution of 1-nitropropane (4.5 g.) in methyl alcohol (20 c.c.). 2-Chloroethyl *n*-butyl sulphone (9.3 g.) was then added and the mixture was stirred at 20° for 18 hours. The solution was diluted with water (50 c.c.) and the precipitate collected (1.45 g.) and recrystallised from alcohol, giving colourless needles, m. p. 104°, not depressed on admixture with 3-nitro-1:5-di-(*n*-butylsulphonyl)-3-ethylpentane. Interaction of an aqueous solution of the sodium salt of *n*-butyl 3-nitroamyl sulphone with bromine at 10–15° gave *n*-butyl 3-bromo-3-nitroamyl sulphone, colourless crystals from alcohol, m. p. 55° (Found: S, 9.95; Br, 25.1. $C_9H_{19}O_4NBrS$ requires S, 10.1; Br, 25.3%).

***n*-Butyl 3-Ketoamyl Sulphone (III; R = Et).**—An aqueous solution of the potassium salt of *n*-butyl 3-nitroamyl sulphone, prepared from 1-nitropropane (4.5 g.) and *n*-butyl vinyl sulphone (7.5 g.) as above, was slowly added to a stirred solution of sulphuric acid (6.5 c.c.) in water (30 c.c.) at 10–15°. Stirring was continued for 30 minutes and the precipitate (4.5 g.) was collected, washed with water, and crystallised from alcohol, giving the ketone as colourless needles, m. p. 89° (Found: S, 15.45. $C_9H_{18}O_5S$ requires S, 15.5%). The 2:4-dinitrophenylhydrazones, m. p. 132°, formed yellow needles from alcohol (Found: N, 14.05; S, 7.8. $C_{11}H_{18}O_6N_4S$ requires N, 14.5; S, 8.3%). The ketone was also formed by acidification of the alkaline filtrate obtained in the condensation of 1-nitropropane with 2-chloroethyl *n*-butyl sulphone (see above).

Tris-(2-methylsulphonyl)nitromethane (IV).—Nitromethane (6 g.), methyl vinyl sulphone (34 g.), alcohol (80 c.c.), and aqueous potassium hydroxide (1 c.c. of 33%) were refluxed for 6 hours. After cooling, the precipitate (20.6 g.) was collected, washed with alcohol, and crystallised from 2-ethoxyethyl alcohol and from acetic acid, giving colourless crystals of the trisulphone, m. p. 219–220° (Found: N, 3.9; S, 25.0. $C_{10}H_{20}O_6NS_3$ requires N, 3.7; S, 25.3%).

Tris-(2-methylsulphonyl)ethylmethylamine.—The nitro-compound (10 g.) was suspended in water (250 c.c.) and shaken with hydrogen and Raney nickel at 20°/1 atm. until absorption was complete. The mixture was then heated to the boil, filtered from catalyst, and allowed to cool. The amine separated in colourless needles, m. p. 218° (Found: N, 4.15; S, 27.25. $C_{10}H_{22}O_6NS_3$ requires N, 4.0; S, 27.5%).

3-Nitro-1:5-di-*p*-tolylsulphonyl-3-ethylpentane (I; R = Et, R' = *p*-MeC₆H₄).—1-Nitropropane (3 g.), *p*-tolyl vinyl sulphone (10 g.), and aqueous potassium hydroxide (1 c.c. of 33%) in alcohol (40 c.c.) were refluxed for 16 hours, cooled, and the solid sulphone which separated was crystallised from acetone, giving white needles, m. p. 151° (Found: C, 55.6; H, 5.8; N, 3.25. $C_{21}H_{27}O_6NS_2$ requires C, 55.6; H, 6.0; N, 3.1%).

2-Nitro-4-*p*-tolylsulphonyl-2-methylbutane (VI).—2-Nitropropane (6 g.), *p*-tolyl vinyl sulphone (10 g.), alcohol (40 c.c.), and aqueous potassium hydroxide (1 c.c. of 33%) were refluxed for 16 hours. After cooling, the separated solid was collected and crystallised from alcohol, giving white needles of the

sulphone, m. p. 122° (Found: C, 52.95; H, 6.2; N, 4.85. $C_{12}H_{17}O_4NS$ requires C, 53.15; H, 6.25; N, 5.15%).

Methyl 3-Nitro-3-p-bromophenylpropyl Sulphone (V; R = Me).—*p*-Bromophenylnitromethane (6 g.) and methyl vinyl sulphone (8 g.) were dissolved in alcohol (40 c.c.) and a few drops of a 33% aqueous solution of methyltriethylammonium hydroxide were added. After 18 hours at 20°, the precipitate (6 g.) was collected and washed with alcohol. Recrystallisation from alcohol gave colourless needles of the *sulphone*, m. p. 142° (Found: N, 4.45; Br, 25.25; S, 10.1. $C_{10}H_{12}O_4NBrS$ requires N, 4.35; Br, 24.85; S, 9.95%).

isoButyl 3-Nitro-3-p-bromophenylpropyl Sulphone (V; R = $CH_3\cdot CHMe_2$).—*iso*Butyl vinyl sulphone (2.5 g.) was added to a solution of the sodium salt of *p*-bromophenylnitromethane (4.0 g.) in water (40 c.c.) and the mixture was stirred at 50° for 6 hours, cooled, and washed with ether. The aqueous solution was treated with acetic acid (2 c.c.), and the separated oil, which solidified on standing, was collected and washed with alcohol. The crude product (2.0 g.) was repeatedly crystallised from alcohol, giving the *sulphone* as colourless needles, m. p. 92° (Found: N, 4.3; Br, 22.2; S, 9.2. $C_{13}H_{18}O_4NBrS$ requires N, 3.85; Br, 22.0; S, 8.8%).

3 : 3'-Dinitro-3 : 3'-dimethyldibutyl Sulphone (IX).—Aqueous potassium hydroxide (1 c.c. of 33%) was added to a solution of 2-nitropropane (8.9 g.) and divinyl sulphone (5.9 g.) in alcohol (40 c.c.). The solution was refluxed for 3 hours, cooled, and the precipitate (7.85 g.) collected and recrystallised from alcohol, giving the *sulphone* as colourless leaflets, m. p. 135° (Found: N, 9.45; S, 10.55. $C_{10}H_{20}O_4N_2S$ requires N, 9.45; S, 10.85%).

3 : 3'-Diamino-3 : 3'-dimethyldibutyl Sulphone.—*3 : 3'-Dinitro-3 : 3'-dimethyldibutyl sulphone* (7.8 g.), suspended in 2-ethoxyethyl alcohol (100 c.c.), was shaken with Raney nickel and hydrogen at 20°/1 atm. until absorption was complete. The filtered solution was concentrated under reduced pressure, and the residue, a viscous semi-solid mass, was dissolved in water, acidified with hydrochloric acid and evaporated to dryness. After extraction with acetone, the *hydrochloride* remained as a white powder (7.2 g.), m. p. 252–255° (Found: N, 8.9; S, 10.3; Cl, 23.0. $C_{10}H_{24}O_2N_2S\cdot 2HCl$ requires N, 9.05; S, 10.35; Cl, 23.0%).

297. Aliphatic Nitro-compounds. Part XVIII. Interaction of Ketones and Nitro-paraffins.

By A. LAMBERT and A. LOWE.

Interaction of acetone and nitromethane in presence of sodium methoxide, sodium hydroxide, quaternary ammonium hydroxides, or triethylamine gives chiefly nitro-*tert*.-butyl alcohol; with secondary amines as catalysts, 1 : 3-dinitro-2 : 2-dimethylpropane is the main product, and this is formed from both nitro-*tert*.-butyl alcohol and 1-nitro-2-methylprop-1-ene with nitromethane. The products obtained from other nitro-paraffins and other ketones are briefly discussed and a reaction mechanism is proposed.

THE literature on the products formed by interaction of ketones and nitro-paraffins, though not extensive, is extremely confusing. According to Fraser and Kon (*J.*, 1934, 604), condensation of acetone and some homologous ketones with nitromethane in the presence of sodium ethoxide, piperidine, pyridine, methylamine, or molecular sodium gives 1 : 3-dinitro-paraffins of the type $RR'C(CH_2\cdot NO_2)_2$ in 15–25% yield. Nitromethane and cyclohexanone with piperidine as a catalyst give 1-nitromethylcyclohexene and a little 1-nitromethylcyclohexanol, and the latter becomes the main product if sodium ethoxide is used as condensing agent. Since completion of the present work, Hass and co-workers (U.S.P. 2,343,256; 2,383,603; cf. *Chem. Reviews*, 1943, 32, 383; *Ind. Eng. Chem.*, 1943, 35, 115) have described improved yields of 1 : 3-dinitro-paraffins from nitromethane and aliphatic or alicyclic ketones by using aliphatic amines as catalysts. They also report failure to duplicate Fraser and Kon's work, saying (U.S.P. 2,343,256) "this disclosure is inoperative and does not enable one skilled in the art to obtain the compounds described".

In addition to the dinitro-paraffins, Hass also obtains from acetone and nitromethane some 1-nitro-2 : 2-dimethylpentan-4-one in yields which vary with the relative proportions of the reactants; with methyl ethyl ketone, some 1-nitro-2-ethylbut-2-ene is produced.

We have now found that, with sodium methoxide as catalyst, nitromethane and aliphatic ketones give only nitro-tertiary alcohols.

e.g., acetone and nitromethane gave nitro-*tert*.-butyl alcohol in 62% yield. Similar results were obtained with sodium hydroxide, quaternary ammonium hydroxides, or triethylamine as catalyst. However, by using secondary amines (diethylamine or piperidine), 68% of

1 : 3-dinitro-2 : 2-dimethylpropane was formed, but with *n*-amylamine the main product was again nitro-*tert*.-butyl alcohol.

Nitromethane and methyl ethyl ketone in the presence of piperidine have given a mixture of 1-nitro-2-methylbut-1-ene, 1-nitro-2-methylbutan-2-ol, and 2 : 2-di(nitromethyl)butane. The isolation of these compounds from one experiment, together with the formation of 1 : 3-dinitro-2 : 2-dimethylpropane from both nitro-*tert*.-butyl alcohol and 1-nitro-2-methylprop-1-ene with nitromethane, indicates that the reaction proceeds as follows :

Hass *et al.* (*loc. cit.*) put forward this mechanism but were unable to isolate any nitro-tertiary alcohol. It is unlikely that 1-nitro-2-diethylamino-2-methylpropane (formed from diethylamine and the nitro-olefin; see this series, Part VII) is an important intermediate product, since on reaction with nitromethane this substance gives only small yields of 1 : 3-dinitro-2 : 2-dimethylpropane.

When cyclohexanone and nitromethane were brought into reaction in the presence of diethylamine, 1-nitromethylcyclohexane, 1-nitromethylcyclohexanol and a small amount of 1 : 1-di(nitromethyl)cyclohexane were formed (*cf.* Fraser and Kon, *loc. cit.*), together with an unidentified product, m. p. 270–271° (acetyl derivative, m. p. 128–129°). The analyses of these agreed with an empirical formula, $\text{C}_{14}\text{H}_{20}\text{O}_3\text{N}_2$, but the apparent molecular weight varied with the method used for the determination.

EXPERIMENTAL.

Nitro-*tert*.-butyl Alcohol.—A mixture of sodium methoxide solution [from sodium (2 g.) and methyl alcohol (50 c.c.)], nitromethane (122 g.), and acetone (600 c.c.) was stirred for 3 days at 20°. After neutralisation (10*N*-hydrochloric acid) and filtration from salt, fractionation gave unchanged nitromethane (62 g.) and nitro-*tert*.-butyl alcohol (71.4 g.) as a colourless oil, b. p. 76–77°/10 mm. (Found : C, 40.7; H, 7.5; N, 11.85. $\text{C}_4\text{H}_9\text{O}_2\text{N}$ requires C, 40.3; H, 7.55; N, 11.75%). Nitro-*tert*.-butyl acetate, prepared from the alcohol by boiling it with acetic anhydride, is a colourless liquid, b. p. 86–88°/13 mm. (Found : N, 8.75. $\text{C}_6\text{H}_{11}\text{O}_4\text{N}$ requires N, 8.7%).

1-Nitro-2-methylprop-1-ene.—Nitro-*tert*.-butyl acetate (7.7 g.) was heated with sodium acetate (0.035 g.) at 110° for 30 minutes, and the mixture then distilled under reduced pressure. The distillate, b. p. 45–65°/12 mm., was diluted with ether, washed with water, dried, and fractionated, giving 1-nitro-2-methylprop-1-ene (4 g.) as a pale yellow liquid, b. p. 54–56°/11 mm. (*cf.* Levy and Scaife, *in the press*).

1 : 3-Dinitro-2 : 2-dimethylpropane.—(a) *From acetone and nitromethane.* A mixture of nitromethane (61 g.), acetone (58 g.), and diethylamine (21.5 g.) was kept at 20° for 28 days, poured into water, acidified (2*N*-hydrochloric acid), and extracted with chloroform. Fractionation of the dried extract gave 1 : 3-dinitro-2 : 2-dimethylpropane (55.5 g.) as an almost colourless liquid, b. p. 130–132°/10 mm., rapidly solidifying to an amorphous mass, m. p. 75–80° (Found : C, 37.2; H, 6.3; N, 17.5. $\text{C}_8\text{H}_{10}\text{O}_4\text{N}_2$ requires C, 37.0; H, 6.2; N, 17.3%).

The same substance was obtained in equal yield using piperidine in place of diethylamine; with *n*-amylamine as catalyst, only 2.5% of the dinitro-compound was formed, together with 10% of nitro-*tert*.-butyl alcohol.

(b) *From nitro-tert.-butyl alcohol and nitromethane.* A mixture of nitro-*tert*.-butyl alcohol (38 g.), nitromethane (20 g.), and piperidine (3 g.) was kept at 20° for 14 days. After working up in the usual way, nitro-*tert*.-butyl alcohol (2 g.) and 1 : 3-dinitro-2 : 2-dimethylpropane (19.8 g.) were obtained. Use of *n*-amylamine in place of piperidine reduced the yield of dinitro-paraffin to 8.2 g., 20 g. of the nitro-alcohol being recovered unchanged.

(c) *From nitro-tert.-butyl alcohol.* A mixture of nitro-*tert*.-butyl alcohol (24 g.) and diethylamine (20 g.) was kept at 20° for 6 days. After acidification (2*N*-hydrochloric acid), the mixture was extracted with ether and the extract fractionated, giving 1-nitro-2-methylprop-1-ene (2 g.), b. p. 54–56°/11 mm., nitro-*tert*.-butyl alcohol (3.4 g.), b. p. 75–76°/10 mm., and 1 : 3-dinitro-2 : 2-dimethylpropane (8.6 g.), b. p. 130–132°/10 mm.

(d) *From 1-nitro-2-methylprop-1-ene and nitromethane.* A mixture of 1-nitro-2-methylprop-1-ene (20 g.), nitromethane (12 g.), and diethylamine (3 g.), after 14 days at 20° and working up in the usual way, yielded unchanged nitro-olefin (7.8 g.) and 1 : 3-dinitro-2 : 2-dimethylpropane (6 g.), b. p. 130–132°/10 mm.

(e) *From 1-nitro-2-diethylaminoisobutane and nitromethane.* The nitro-amine was prepared by interaction of 1-nitro-2-methylprop-1-ene (5.05 g.) and diethylamine (3.7 g.) in dry ether (15 c.c.) at 0° for 1 hour. Evaporation of the ether gave an almost completely crystalline mass of 1-nitro-2-diethylaminoisobutane, which separated from ether on strong cooling as yellow needles, m. p. 76°. Yield, 48%. The nitro-amine decomposed rapidly on keeping and could not be analysed.

A mixture of the nitro-amine (14 g.) and nitromethane (6 g.) in ether (15 c.c.) was kept at 20° for 15 days. The yellow nitro-amine dissolved after 24 hours and the smell of diethylamine became apparent. After acidification, extraction with ether, and distillation, 1 : 3-dinitro-2 : 2-dimethylpropane (1.8 g.), b. p. 130–132°/10 mm., was obtained.

(f) *From nitro-tert.-butyl acetate and nitromethane.* A mixture of nitro-*tert*.-butyl acetate (14 g.), nitromethane (6 c.c.), and piperidine (2 c.c.) was kept at 20° for 16 days and worked up in the usual way. 1 : 3-Dinitro-2 : 2-dimethylpropane (5.1 g.), b. p. 134–135°/10 mm., was obtained.

1-Nitro-2-methylbutan-2-ol.—A mixture of nitromethane (61 g.), methyl ethyl ketone (150 c.c.), and

methyltriethylammonium hydroxide (3 c.c. of 40% aqueous solution) was kept at 20° for 5 days. The mixture was acidified (10*N*-hydrochloric acid) and distilled; nitromethane (45 g.) was recovered, followed by 1-nitro-2-methylbutan-2-ol (12 g.) as a colourless oil, b. p. 96–97°/18 mm. (Found: C, 44.8; H, 8.0; N, 10.8. $C_6H_{11}O_2N$ requires C, 45.1; H, 8.3; N, 10.5%).

1-Nitro-2-methylbut-1-ene.—(a) From methyl ethyl ketone and nitromethane. A mixture of nitromethane (100 c.c.), methyl ethyl ketone (100 c.c.), and piperidine (8 c.c.) was kept at 20° for 9 days. The solution was acidified (2*N*-hydrochloric acid), extracted with ether, and the extract, after being washed successively with dilute sodium hydrogen carbonate and water, was dried and fractionated, giving 1-nitro-2-methylbut-1-ene (7 g.), b. p. 62°/11 mm. (Found: C, 52.3; H, 7.55; N, 12.2. $C_6H_9O_2N$ requires C, 52.2; H, 7.8; N, 12.2%), 1-nitro-2-methylbutan-2-ol (4.4 g.), b. p. 90–91°/11 mm., and 2:2-di(nitromethyl)butane (11.4 g.), b. p. 92°/0.05 mm. (Fraser and Kon, *loc. cit.*, give b. p. 135–138°/9 mm.).

(b) From 1-nitro-2-methylbutan-2-ol and nitromethane. A mixture of 1-nitro-2-methylbutan-2-ol (13.3 g.), nitromethane (6.1 g.), and piperidine (3 c.c.) was kept at 20° for 14 days and worked up in the usual way. 2:2-Di(nitromethyl)butane (12.7 g.), b. p. 106–108°/1 mm., was obtained.

3-Nitro-2-methylbutan-2-ol.—A solution of sodium methoxide [from sodium (3 g.) and methyl alcohol (60 c.c.)] was mixed with nitroethane (225 g.) and acetone (935 c.c.) and the mixture stirred at 20° for 5 days. After acidification (10*N*-hydrochloric acid), filtration from salt and fractionation, nitroethane (170 g.) was recovered and 3-nitro-2-methylbutan-2-ol (51 g.) was obtained as a colourless oil, b. p. 85–86°/14 mm. (Found: C, 45.4; H, 8.0; N, 10.7. $C_6H_{11}O_3N$ requires C, 45.1; H, 8.3; N, 10.5%).

1:3-Dinitro-2:2-dimethylbutane.—A mixture of nitro-*tert*-butyl alcohol (60 g.), nitroethane (32.5 g.) and piperidine (10 c.c.) was kept at room temperature for 3 months. After neutralisation and fractionation, 1:3-dinitro-2:2-dimethylbutane (1 g.), b. p. 128–132°/9 mm., was obtained (Found: N, 15.9. $C_8H_{15}O_4N_2$ requires N, 15.9%).

1:1-Di(nitromethyl)cyclohexane.—(a) From cyclohexanone and nitromethane. A mixture of cyclohexanone (50 c.c.), nitromethane (30 c.c.), and diethylamine (35 c.c.) was refluxed for 10 hours. The solution was acidified (2*N*-hydrochloric acid) and extracted with ether. A colourless solid (12 g.) separated at this point, and was collected and crystallised from 2-ethoxyethyl alcohol, giving colourless prisms of a substance, m. p. 270–271° [Found: C, 63.9; H, 7.3; N, 10.8; *M* (by X-ray determination), 259. $C_{14}H_{20}O_2N_2$ requires C, 63.9; H, 7.2; N, 10.65%; *M*, 263]; the acetate had m. p. 128–129° [Found: C, 61.5; H, 6.8; N, 8.05; *M* (by X-ray determination), 347. $C_{18}H_{24}O_4N_2$ requires C, 62.0; H, 6.9; N, 8.05%; *M*, 348]. The constitution of this substance is unknown.

Fractionation of the ethereal solution gave 1-nitromethylcyclohexene, 1-nitromethylcyclohexanol, and 1:1-di(nitromethyl)cyclohexane (3 g.) as a colourless oil, b. p. 105°/0.1 mm., n_D^{20} 1.4963 (Found: N, 14.2. $C_8H_{14}O_2N_2$ requires N, 13.9%).

(b) From nitromethylcyclohexanol and nitromethane. 1-Nitromethylcyclohexanol (30 g.; Fraser and Kon, *loc. cit.*), nitromethane (15 c.c.), and diethylamine (5 c.c.) were refluxed for 12 hours. After acidification and extraction with ether [some solid, m. p. 270–271° (1.9 g.), separated here; see above], fractionation of the dried extract afforded 1:1-di(nitromethyl)cyclohexane, b. p. 110°/0.2 mm. (Found: N, 13.6%).

3-Amino-2-methylbutan-2-ol.—3-Nitro-2-methylbutan-2-ol (48 g.) in methyl alcohol (900 c.c.) was hydrogenated using Raney nickel at 20°/85 atms. (initial pressure). Fractionation of the filtered solution afforded 3-amino-2-methylbutan-2-ol as a colourless oil, b. p. 65–67°/17 mm. (Found: C, 58.6; H, 12.35; N, 13.9. $C_6H_{11}ON$ requires C, 58.2; H, 12.7; N, 13.6%).

1:3-Diamino-2:2-dimethylpropane.—Hydrogenation of 1:3-dinitro-2:2-dimethylpropane (25 g.) in methyl alcohol (500 c.c.) with Raney nickel (10 g.) at 20°/42 atms. (initial pressure) gave an oil, b. p. 146–156°, which on redistillation from solid potassium hydroxide yielded 1:3-diamino-2:2-dimethylpropane (11.2 g.) as a colourless oil, b. p. 154–156° (Found: C, 58.4; H, 13.6; N, 27.0. Calc. for $C_6H_{11}N_2$: C, 58.8; H, 13.7; N, 27.4%). The dihydrochloride formed prisms from alcohol, m. p. 259°; the dibenzoyl derivative, leaflets from aqueous methyl alcohol, m. p. 152° alone and in admixture with an authentic specimen prepared according to Part XII of this series.

1:1-Di(aminomethyl)cyclohexane.—Reduction of 1:1-di(nitromethyl)cyclohexane (5.5 g.) as described above gave 1:1-di(aminomethyl)cyclohexane (2.6 g.) as a colourless liquid, b. p. 106–108°/10 mm. (Found: C, 67.5; H, 12.3. $C_8H_{18}N_2$ requires C, 67.6; H, 12.7%). The dibenzoyl derivative had m. p. 210° (Found: C, 75.3; H, 7.5; N, 8.0. $C_{22}H_{26}O_2N_2$ requires C, 75.4; H, 7.4; N, 8.0%).

The authors wish to thank Dr. H. A. Piggott and Mr. J. D. Rose for advice and interest in this work.

[Received, January 23rd, 1947.]

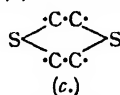

298. The Reaction of Sulphur and Sulphur Compounds with Olefinic Substances. Part I. The Reaction of Sulphur with Mono-olefins and with $\Delta^1:5$ -Diolefins.

By E. HAROLD FARMER and F. W. SHIPLEY.

The nature of the reaction occurring at 140° between sulphur and two classes of olefins has been investigated. Olefins in general give olefin sulphides, $R\cdot S_2\cdot R'$, in which on the average half the original unsaturation is lost and x has values up to 6. In the sulphides from mono-olefins R and R' appear on average to be mono-olefinic and saturated respectively, except that

some redistribution appears to occur in the sulphides from hydroaromatic mono-olefins owing to the facility of occurrence of (probably secondary) dehydrogenation reactions. $\Delta^{1:5}$ -Olefins give in addition to diolefin sulphides, $R \cdot S \cdot R'$, cyclic monosulphides which are formed from only one molecule of olefin. Thus, polyolefins displaying suitably-spaced unsaturation become both inter- and intra-molecularly cross-linked by the sulphur taken into combination. The reaction mechanism is discussed, and it is noteworthy that although substitutive and additive reactions of a radical type play an important role, additive reactions of a polar nature also participate.

THE idea has long been current that sulphur reacts with olefins in an essentially additive manner, although there is no body of evidence in the literature to relate the behaviour of sulphur as a reagent for double bonds with that of any of the numerous common additive reagents. The character of sulphur-olefin reactivity has long been a matter of interest in connexion with the mechanism of vulcanisation of rubbers and of drying oils, but the experiments and speculations of Erdmann (*Annalen*, 1908, 362, 133), Kirchoff (*Kolloid-Z.*, 1913, 13, 49; 1914, 14, 35), Prins (*Chem. Weekblad*, 1917, 14, 932), and many others on this subject have done little to solve the basic problem, as it applies either to high-molecular natural and artificial rubbers or to quite simple olefins such as isobutylene and cyclohexene. Episulphides (thioepoxides) and cyclic disulphides containing respectively the groupings (a) and (b) appear definitely never to have been obtained by the action of sulphur on olefins, and there seems to be no sound evidence to support the view that alternative structures such as (c) and (d) are formed additively at ethylenic centres.

It is necessary, therefore, to find a new basis for formulating the course of reaction of sulphur, and in this connexion attention turns to the behaviour of the closely related element oxygen, which, also, until recently was regarded as functioning normally as a common additive reagent. Sulphur, like oxygen, contains two unpaired electrons in its outer shell, and since it shows no obvious signs in its recorded behaviour of functioning as a polar reagent it may be suspected of resembling oxygen in possessing an inherent tendency to react apolarly. Hence methods which have been successfully used in the investigation of oxygen-reactivity have been applied to the determination of the principles governing sulphur reactions. In conducting the work it has been necessary, as in the comparable oxygen studies, to divide olefins into four classes, *viz.*, (1) mono-olefins, (2) di- and poly-olefins displaying uni-spaced (*i.e.*, 1 : 4-, 1 : 4 : 7-, etc.) unsaturation, (3) di- and poly-olefins displaying bi-spaced (*i.e.*, 1 : 5-, 1 : 5 : 9-, etc., unsaturation) and (4) conjugated di- and poly-olefins, since the detailed course of reaction is greatly influenced by the unsaturation pattern.

The reaction of sulphur with olefinic materials usually becomes appreciable above 100°, and proceeds at a moderate speed at 140°, which is the most usual vulcanisation temperature for rubbers. This, the lowest temperature at which a convenient speed of reaction is obtained, was adopted for our experiments, not merely because of its common use in industrial vulcanisation processes, but also because experience soon showed that operation at substantially higher temperature is attended by serious danger of confusion arising between primary and secondary reactions. A beginning has been made by the investigation of the reaction between sulphur and cyclohexene, this being of special interest, both because this reaction has twice already been examined by previous workers (Jones and Reid, *J. Amer. Chem. Soc.*, 1938, 60, 2452; Meyer and Hohenemser, *Helv. Chim. Acta*, 1935, 18, 1061) with results which are difficult to interpret, and because it brings into consideration whatever relationship there may be between the general or ordinary reactivity of sulphur and the possibly specialised reactivity underlying the Vesterberg procedure for the dehydrogenation of hydroaromatic compounds.

Reaction with cyclohexene.—When cyclohexene is heated with sulphur for several hours in a glass tube or steel autoclave containing air, there is obtained a mixed product composed of sulphurated and unsulphurated materials. The recovered hydrocarbon is wholly unimolecular and contains only a trivial amount of cyclohexadiene and benzene (<1%, determined spectroscopically as benzene), so that simple dehydrogenation of the cyclohexene to a more highly unsaturated state is not an important reaction at 140° (the Vesterberg reaction is usually carried out at 200° and above), unless the cyclohexadiene which is produced is subsequently used up in reaction with sulphur or hydrogen sulphide. The sulphurated products have a very large range of boiling point, but are very sensitive to elevated temperatures, even to those but little higher than the original reaction temperature, so that separation of the products by distillation must be conducted by "molecular" distillation, otherwise progressive (and hitherto unsuspected)

thermal degradation sets in, with formation of moderate yields of alkylthiol, dialkyl sulphide, and hydrogen sulphide. If the distillation temperature is kept below 150° , only the merest traces of hydrogen sulphide and thiol are formed, and the main bulk of material is easily separable with tolerable sharpness into a series of polysulphides $R\cdot S\cdot R'$, $R\cdot S_2\cdot R'$, $R\cdot S_3\cdot R'$, and $R\cdot S_4\cdot R'$. These are the invariable products of reaction under the stated conditions, but they can be progressively broken down at will by being heated for long periods at higher temperatures, and there is no doubt at all that the thiol, hydrogen sulphide, and possibly much of the monosulphide reported by the previous workers, are degradation products, and therefore only *secondary* products, of the olefin-sulphur reaction. The pentasulphide $R\cdot S_5\cdot R'$ derived from *cyclohexene* stands at about the limit of practical distillability for non-rotary molecular stills operating at 10^{-5} – 10^{-6} mm. pressure and temperatures below 150° ; therefore its separation from the higher-boiling residue tended always to be very incomplete, and, in consequence, the total bulk too small to permit of its satisfactory rectification. It is perhaps significant that the undistilled residue before removal of any pentasulphide had an average composition agreeing almost exactly with that required for the hexasulphide. Variation in the proportion of sulphur employed within the observed limits of $\frac{1}{3}$ to $\frac{2}{3}$ atom of sulphur per mol. of olefin affects mainly the yield, and not the nature of the sulphides obtained.

It was at once noticeable that the alkyl radicals in these polysulphides were not wholly saturated, and, indeed, the hydrogen contents of the sulphides as determined by the most careful technique of elementary analysis available usually lay but a little above * those required for the formula $C_6H_9\cdot S_x\cdot C_6H_{11}$, or alternatively those required for an equimolecular mixture of $C_6H_9\cdot S_x\cdot C_6H_9$ and $C_6H_{11}\cdot S_x\cdot C_6H_{11}$ together with (possibly) some small or large proportion of admixed $C_6H_9\cdot S_x\cdot C_6H_{11}$. In other words *the atom-ratio of hydrogen to carbon (H/C) in all the sulphides produced (in the primary reaction) by sulphuration was found to be identical, within the limits of analytical error, with that of the original olefin, which signified that no serious net gain or loss of hydrogen as hydrogen sulphide or thiol could have occurred to that portion of the hydrocarbon which became successfully converted into sulphides*, and hence meant that any postulation of dehydrogenation of the hydrocarbon to give hydrogen sulphide as the first necessary stage of sulphur attack must require as a corollary the complete re-addition of the hydrogen sulphide to the olefinic materials present, and must correspondingly preclude any *overall* hydrogen-enrichment of the sulphurated products at the expense of concomitantly stripped hydrocarbon molecules, but not necessarily the enrichment of individual sulphurated species (disulphides, trisulphides, etc.) at the expense of each other.

The accurate determination of total unsaturation in the partly olefinic sulphides presents a difficult practical problem which has not been satisfactorily solved: catalytic hydrogenation methods fail owing to catalyst poisoning, and all halogen addition methods which we have sought to use are invalidated owing to the high co-ordinating capacity for halogens of the combined sulphur atoms.† The determination of the distribution of unsaturation presents a still more difficult problem. At first, owing to definite analytical indications (derived from the magnitude of the hydrogen contents) that the unsaturation of the polysulphides varied appreciably within the same individual species (*i.e.*, from one sub-fraction to another), and also to the fact that a quite considerable proportion of pure saturated *dicyclohexyl* sulphide could be isolated in the form of its methiodide from the monosulphide derived from *cyclohexene*, it seemed likely that each species of sulphide (mono-, di-, etc.) contained some saturated material, $R_{sat}\cdot S_x\cdot R_{sat}$, and some dialkenyl material, $R_{\overline{1}}\cdot S_x\cdot R_{\overline{1}}$ —these in equimolecular proportions—probably in addition to the “average compound” $R_{sat}\cdot S_x\cdot R_{\overline{1}}$. This generalisation is probably true in respect of the sulphuration products derived from most mono-olefins, but it does not appear to be true of the sulphurated products from hydroaromatic mono-olefins because in such examples a subsidiary phenomenon seems to enter to complicate the normal course of reaction. Infra-red spectroscopic evidence ‡ shows that much of the unsaturation surviving in the sulphides from *cyclohexene* is conjugated unsaturation, and the most likely source of this conjugation (in view of its complete absence from the synthetically derived sulphides of all olefins and polyolefins so far examined) § is dehydrogenation, doubtless produced by secondary

* This excess doubtless merely reflects the usual tendency of hydrogen values to be rather high.

† Some progress in respect of halogen-addition methods has been made by Bloomfield (*cf. J. Soc. Chem. Ind.*, 1945, 64, 274) since this work was carried out.

‡ We record our great indebtedness to Dr. G. B. M. Sutherland and Mr. N. Sheppard for their invaluable co-operation in the determination of the structure of sulphur compounds. All items of infra-red spectroscopic evidence herein depend on their observations.

§ The possibility that resonance in groups of vinyl sulphide type ($\cdot C\equiv C\cdot S\cdot$) is in some degree responsible has not yet been specifically examined.

reaction. There is every reason to suspect that the superior ease of dehydrogenation of *cyclohexene* over *cyclohexane* is due to the susceptibility of the α -methylenic hydrogen atoms to removal (as atoms) by the reagent, permitting the *cyclohexenyl* radicals so formed to achieve stabilisation by disproportionation ($2C_6H_9 \cdot \rightarrow C_6H_8 + C_6H_{10}$), or by donation of a second hydrogen atom to sulphur or to $\cdot SH$ radicals; there is no obvious reason why the *cyclohexenyl* groups of sulphides $R \cdot S_x \cdot R'$ should be immune from similar dehydrogenation, but of course to the extent that the unsaturation of some of the groups R and R' is increased, that of others must ultimately disappear, so that the overall (or average) unsaturation is not quantitatively altered. There are no experimental indications that any considerable amount of free hydrogen sulphide (rather than $\cdot SH$ or $\cdot S_2H$) is ever produced by dehydrogenation reactions and therefore used up again in additive reactions, although minor reactivity of this type is not unlikely.

Reaction with 1-Methylcyclohexene.—The reaction followed exactly similar lines to that observed for *cyclohexene*. Only a trace of free hydrogen sulphide and no thiol was formed; also the amount of monosulphide, $R \cdot S \cdot R'$, produced was very small. That portion of the product which was distillable under high vacuum below 150° consisted of mono-, di-, tetra-, and penta-sulphides, the last being distillable only with great difficulty and hence not completely isolable from the high-boiling residue, or wholly separable from admixture with the tetra-sulphide. The sulphides again agreed in composition with the general formula $R \cdot S_x \cdot R'$, the groups RR' containing between them, on average, one double bond. Probably conjugation due to dehydrogenation appears in these sulphides (although this has not been experimentally verified), so precluding them from representation by the average formula $C_7H_{11} \cdot S_x \cdot C_7H_{13}$ or by the equivalent mixture of saturated and diolefinic forms $C_7H_{13} \cdot S_x \cdot C_7H_{13}$ and $C_7H_{11} \cdot S_x \cdot C_7H_{11}$.

Reaction with isoButylene.—In this instance also there was no appreciable amount of hydrogen sulphide or thiol produced, and the lowest sulphide isolated was $R \cdot S_2 \cdot R'$. This, together with the tri- and tetra-sulphide, formed almost the whole reaction product. No conjugation of the groups R and R' was observed in this case.

Reaction with Diolefins.—The manner of reaction of two bi-spaced olefins of the terpene group, *viz.*, dihydromyrcene, $CH_3 \cdot CMe \cdot CH \cdot CH_2 \cdot CH_2 \cdot CMe \cdot CH \cdot CH_3$, and geraniolene, $CH_3 \cdot CMe \cdot CH \cdot CH_3 \cdot CH_2 \cdot CMe \cdot CH_2$ was next examined, the thermal treatment being conducted as before. With dihydromyrcene about two-thirds of the hydrocarbon was recovered in un-sulphurated condition. Of the sulphurated products about half consisted of a mobile *mono-sulphide* $C_{10}H_{18}S$, which from its low boiling point, its not unpleasant smell, the zero value of its active hydrogen content, and the total absence of thiol reactivity, was clearly a cyclic sulphide. The remaining half was a red, viscous oil, easily decomposable, when heated above 140° or very slowly at 140° when no solvent or excess hydrocarbon was present; this product was wholly undistillable except at 10^{-5} – 10^{-6} mm. in a molecular still, and apparently consisted of mixtures of sulphides of the type $R \cdot S_x \cdot R'$ analogous to these described above. The mono-sulphide readily formed a crystalline sulphonium iodide with methyl iodide and had a H/C ratio indistinguishable from that of the parent dihydromyrcene. The latter characteristic ruled out the possibility that hydrogen sulphide formed by dehydrogenation of some of the hydrocarbon molecules had added to the double bonds of other molecules to give a *saturated* cyclic product (*e.g.*,

Indeed, observation of the infra-red spectrum showed unmistakably that the monosulphide was unsaturated, and also revealed the presence of certain characteristic olefinic groupings (see below).

Geraniolene behaved in a precisely similar manner with sulphur at 140° , the sulphurated product containing a large proportion of olefinic cyclic sulphide $C_9H_{16}S$ and a residue of mixed sulphides which appeared to be of type $R \cdot S_x \cdot R'$.

Formulation of the Sulphides. Open-chain Sulphides.—The method of linking of the sulphides derived from *cyclohexene*, 1-methylcyclohexene, and *isobutylene* was first examined by desulphuration. The removal of sulphur by hydrogenolysis from open-chain forms $R \cdot S_x \cdot R'$ should give simple saturated hydrocarbons RH , $R'H$ (RH_2 or $R'H_2$ if R or R' is olefinic),

whereas its removal from forms such as $S < \begin{array}{c} \text{C} - \text{C} \\ | \quad | \\ \text{C} - \text{C} \end{array}$, showing carbon-to-carbon cross-linking,

would inevitably give hydrogenated hydrocarbon dimers $R-R$ (or $RH_2 \cdot R$, $RH_2 \cdot RH_2$, etc., if the sulphide is olefinic). Bougault and his co-workers had shown that sulphur can be entirely

removed from a wide range of sulphur compounds by acting on them with Raney nickel containing adsorbed hydrogen; Mozingo (*J. Amer. Chem. Soc.*, 1943, **65**, 1013) had later shown that the action in the case of typical organic sulphides consisted in the severing of the C-S bonds with formation of the corresponding simple hydrocarbons: $R \cdot S \cdot R' \xrightarrow{2H_2} RH + R'H + H_2S$.

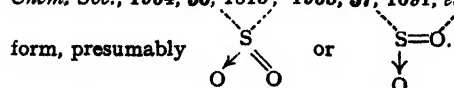

The procedure was applied to the total sulphur product from cyclohexene, 1-methylcyclohexene, and isobutylene, and also to homogeneous monosulphides such as dicyclohexyl and dicyclohexenyl sulphides. In each case there remained volatile (unimolecular) hydrocarbons free from corresponding dimeric (carbon-to-carbon cross-linked) forms.

It appears, therefore, that sulphur molecules (probably chains of sulphur atoms derived by rupture of S_x rings) unite at either end with olefin molecules in virtue of the reactivity of their terminal atoms. It may tentatively be considered that such open-chained sulphur molecules will have radical ends.† In the case of the monosulphides (which are formed usually in small yield) there are two possible routes of formation: they may result from the union of single sulphur atoms (presumably $\cdot S \cdot$) with the olefins, or from the degradation of already formed polysulphides or polysulphide radicals, $R \cdot S_x \cdot$, to give $RS \cdot$. Experience has shown that when sulphur is liberated in the course of a thermal decomposition reaction (presumably in atomic condition) it is energetically reactive towards olefins, whereas elementary sulphur reacts quite slowly, even with very reactive olefins such as polyisoprenes. There is some ground, therefore, for suspecting that the small yields of monosulphides ordinarily obtained in cautiously conducted olefin-sulphur reactions may not arise from the action of monatomic sulphur. It is convenient, however, in order to simplify the argument, to assume provisionally in the following section that the reagent is monatomic biradical sulphur.

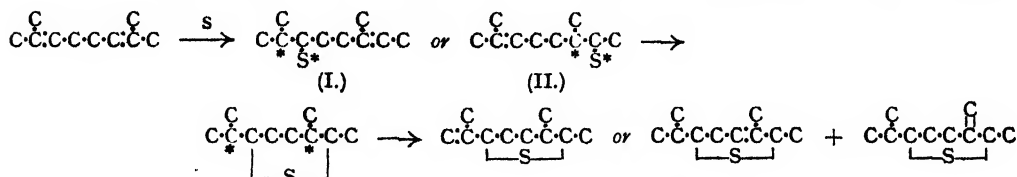

Cyclic Forms.—Owing to (1) the plurality of reaction paths open to the olefin and the sulphur reagent (having regard to the potential versatility of both), and (2) the strong possibility that cyclisation will lead to the formation of both 5- and 6- (but not 3-, 4-, and 7-) membered rings, there is little likelihood that the cyclic products formed respectively from dihydromyrcene and geraniolene will be homogeneous compounds. Efforts to separate pure or tolerably pure isomeric or structurally related forms from the two volatile sulphides—either by direct fractionation or by the formation of crystalline derivatives—proved abortive. The probability of their structural heterogeneity, however, is enhanced by the complexity of their infra-red absorption spectra in comparison with the spectra of authentic specimens of allied 6-membered saturated cyclic sulphides. The absorption curves, indeed, were in each case too complex to reveal directly the precise character of all the compounds, and for the present, necessary comparisons with corresponding 5-membered forms have had to be omitted owing to difficulties attending synthesis of the latter. But although complete interpretation of the data has not yet been possible, the deductions which have been made from a partial analysis (*q.v.*) are illuminating.

It is necessary to envisage that a radical reagent may in general attack an olefin either by replacing an α -methylenic hydrogen atom or by adding to the double bond, and it is not *a priori* impossible for the two types of reaction to occur side by side. The degree of variability to be associated with the α -methylenic (substitutive) type of reaction is mainly, but not solely (see below), that arising from the presence of two or more α -methylenic groups in the olefin undergoing attack, with the resultant possibility that attack may be initiated at more than one point in the olefinic chain. The degree of variability to be associated with the additive reaction is (for a mono-olefin) only that which could arise if the radical reagent possesses the ability to add at either end of the double bond. Now it has already been suggested by one of us (Farmer, *J. Soc. Chem. Ind.*, 1947, **66**, 86) that the addition of radicals and radical reagents to unsymmetrical alkylethylenes is just as strictly and universally governed by a "radical-addition" rule as is the corresponding addition of polar reagents by the well-known "polar-addition" rule of Markovnikov. Thus, whereas Br^- would always add to the alkylated carbon atom in $CHR:CH_2$, $Br \cdot$ (and the same applies also to other radical addenda) could just as inevitably add, if it added at all, to the other carbon atom.

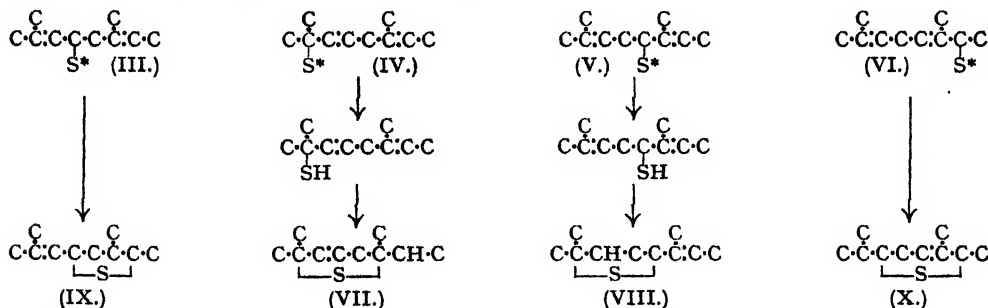

† Molecular oxygen appears to have both a biradical and an unsaturated form ($\cdot \ddot{O} : \ddot{O} \cdot$ and $\ddot{O} = \ddot{O} \cdot$), the latter of which enables it to form interpolymers with some olefins. Sulphur does not appear to form interpolymers at all and hence presumably has no unsaturated reaction form, but sulphur dioxide forms interpolymers with great ease (Staudinger and Ritzenthaler, *Ber.*, 1935, **68**, 455; Marvel *et al.*, *J. Amer. Chem. Soc.*, 1934, **56**, 1815; 1935, **57**, 1891, *et seq.*) and so must be able to assume a bifunctional reaction

The approach to the determination of the structures present, and to the formulation of an adequate reaction scheme, has been greatly facilitated by Naylor's parallel study of the polar and non-polar addition of hydrogen sulphide to di-isoprenic hydrocarbons (see Part II, following paper); for the results of this study are clear-cut, since not only are the cyclic products then saturated, and so free from troublesome non-uniformity in the degree and position of unsaturation, but the unsaturation pattern of the original di-isoprene is exactly that required to give either by the polar or by the non-polar process *solely* 6-membered sulphide rings. In contrast, the additive reaction which a single sulphur atom may be expected to pursue presents the high probability that marked non-homogeneity will arise in the end-product, since the bi-radical adducts (I and II) which are probably first formed, must achieve stabilisation by hydrogen transfer (*i.e.*,

probably mainly by disproportionation) in such a way that on average one double bond (and that bond not usually one of the original two) is retained and one lost; to some doubtless minor extent, however, the disproportionation may well yield an equimolecular mixture of the corresponding diolefinic and fully saturated sulphides.† If, however, reaction follows the α -methylene course, attack by the reagent is likely to be confined almost entirely to the two α -methylene groups between the two double bonds, leaving those in the methyl groups intact; but owing to the capacity for resonance in any radical propene system that is formed when an α -methylene hydrogen atom is detached ($\text{C}^*\text{C}=\text{C} \rightleftharpoons \text{C}=\text{C}\text{C}^*$) there will be four potential ways (III—VI) in which reaction may be initiated but only two of these, *viz.*, (III) and (VI), will lead to the successful production of cyclic forms if the radical-addition rule is to be obeyed and only 5- and 6-membered rings are capable of formation.

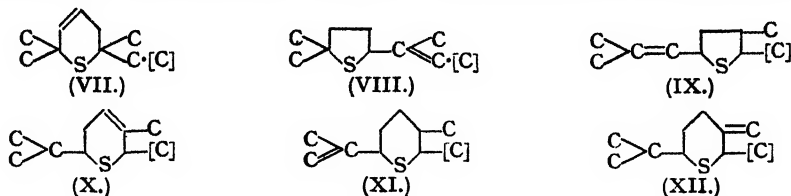

There is, however, a further possibility for the formation of cyclic sulphides which cannot be neglected, *viz.*, that which arises if the active thiol centres in (III—VI) become stabilised by capture of the hydrogen atoms (see preceding footnote) and the resulting $\cdot\text{SH}$ groups thereafter add themselves by polar mechanism (wherever the Markovnikov rule and the usual limitation of ring size jointly permit) to the more remote double bond. This polar type of addition would be likely to occur readily owing to the strong catalytic action of the free sulphur present (see Part II).‡ Of the four α -methylene sulphuro-forms, however, only two, (IV) and (V), would yield cyclic sulphides (*viz.*, VII and VIII); the olefinic thiols corresponding to (III) and (VI), if formed at all, would survive. Actually, the amount of such thiol that survived as determined

† The path taken by the disproportionation probably depends on the incidence of intra- and inter-molecular hydrogen displacements respectively, the former leading exclusively to the product of average unsaturation (*i.e.*, to the mono-olefinic cyclic sulphide) and the latter probably largely to the mixture of saturated and diolefinic forms. To the extent that the addition of the sulphur to one double bond is completed (*i.e.*, the first-formed radical sulphuro-product becomes stabilised by hydrogen rejection *before* that to the other double bond occurs), to that same extent the discarded hydrogen atoms are likely to add to the $\cdot\text{S}^*$ groups giving the thiols corresponding to (III)—(VI).

‡ Since polar and non-polar additions of hydrogen bromide (or hydrogen sulphide) to olefins occur readily side by side, there is no reason to suppose that the two kinds of addition may not occur together in this case.

by usual methods was extremely small, but was possibly slightly underestimated; only later did the very efficient analytical and separative method used in Part II become available. Thus, altogether, the cyclic sulphides likely to be formed from dihydromyrcene by α -methylenic initiation are (VII), (VIII), (IX), and (X); and those from geraniolene precisely the same forms minus the carbo-group (CH_3) enclosed in square brackets. Correspondingly those likely to be formed by additive initiation are (X) and (XI), with possibly a very minor amount of (XII).

Now the infra-red absorption data show that, as regards the 6-membered forms from both dihydromyrcene and geraniolene, the skeletal pattern depicted in (VII) preponderates over that in (X); also it is plain that one or more of the isomers present contains a methyleno-grouping $\text{CH}_2\text{:CRR'}$ such as occurs in (XI) and in the minor isomer (XII). Hence α -methylenic initiation of the sulphuration reaction undoubtedly occurs to an important extent and may well greatly exceed additive initiation. It is of especial interest that the change from the CRR':CHR' structure occurring in the olefinic units of the di-isoprene to the CHR':CHR' structure of the derived cyclic (and doubtless also of the cross-linked) sulphuro-product, as seen in (VII), with all that it implies in the way of α -methylenic initiating attack at a in $\text{CH}_2\text{:CMe:CH-CH}_2$, as discussed above, is encountered again in the sulphuration of rubber, since Sutherland and Sheppard's infra-red spectroscopic data (private communication) show that the progress of this change keeps pace with increase in the uptake of sulphur.

It is to be noted that no products of the episulphide (thioepoxide) type have been discoverable in the fore-runs of the sulphurated mono-olefins or in the cyclic monosulphide fractions from dihydromyrcene and geraniolene; and indeed, no adequately substantiated method of obtaining such compounds save the usual one of reaction between sulphide and suitable halogeno-compounds appears yet to be known. The chemical behaviour of thioepoxycyclohexane, a typical compound of this group, differs considerably from that of the open-chain and cyclic monosulphides discussed above.

Nature of Sulphur Vulcanisation and the Stability of Sulphurated Products.—It has been shown by one of us (Farmer and Michael, J., 1942, 513) that decomposing peroxides effectively promote the carbon-to-carbon cross-linking (α -methylenically initiated) of olefinic materials, and also of ketonic and carboxylated materials (cf. Farmer, "Advances in Colloid Science," 1946, II, 316). Decomposing diazo-compounds often have a similar effect, and with both classes of reagent the process follows a radical mechanism which is irreversible except in so far as the cross-linked products become broken down (and even then not usually into their exact precursors) when they are heated to the point of thermal breakdown of the weakest C-C bonds ($>250^\circ$). With regard to sulphur vulcanisation, the only cross-linking which has been discoverable in the present investigation is that brought about by the linking of the hydrocarbon chains through sulphur atoms or groups of sulphur atoms. The concomitant formation of monosulphide rings in the case of di-isoprenes is to be regarded as amounting to *intramolecular* cross-linking, the different olefinic units becoming joined being in the same instead of in different molecules; such intramolecular linking is of course liable to take place wherever the reactant olefin molecules contain two or more suitably-spaced double bonds. But to the extent that cyclising sulphuration occurs at the expense of true cross-linking, the ingoing sulphur is apparently not used effectively (or at least not in the most effective way) for the conferring of "vulcanised" properties. The sulphur-vulcanisates, as a class, whether formed from short-chained olefins or high-molecular polyolefins, differ greatly from the carbon-to-carbon cross-linked vulcanisates in being highly susceptible to thermal treatment at temperatures but little above (or, possibly, where heating is very unduly prolonged, even at) the vulcanisation temperature. This relative instability (thermolability) appears to be a property of considerable moment in connection with the technology of natural and synthetic rubbers, causing as it does the replacement of some primary structures by secondary ones. The two structural features concerned in this instability are the C-S bonds and (in the case of polysulphides) the polysulphide chains.

The Stability of C-S Bonds.—The susceptibility of C-S bonds to thermal degradation is

reserved for future study. In general, the strength of the bonds as it occurs in cross-linked structures is likely to vary very appreciably with the nature of the hydrocarbon chains in the immediate vicinity of the bond: indeed, having regard to the foregoing results, distinction may be made between three types of monosulphide bridge, *viz.*, (a) the diallylic type, $\text{C}=\text{C}-\text{C}-\text{S}-\text{C}=\text{C}$, (b) the alkyl-allyl type $\text{C}-\text{C}-\text{C}-\text{S}-\text{C}=\text{C}$, and (c) the dialkyl type, $\text{C}-\text{C}-\text{C}-\text{S}-\text{C}-\text{C}$. As regards the stability of the C-S bond to chemical reagents, it has previously been suggested by one of us that the well-known non-uniform action of organic bases on the sulphur vulcanisates of rubber is probably connected with differences in structure near the sulphur bridge; in the present paper, however, attention is confined to evidence concerning the breaking of C-S bonds (a) under the reducing action of sodium in alcohol, and (b) by action of methyl iodide.

Experiment showed that completely saturated sulphides such as di-*n*-propyl sulphide and di-*n*-butyl sulphide remained unattacked by the reducing agent, whereas dialkenyl sulphides such as diallyl, dicrotyl, and dicyclohex-2-enyl sulphides broke down readily to give approximately equimolecular amounts of hydrogen sulphide and thiol, *e.g.*,

Mixed sulphides, of which two (*propyl allyl sulphide* and *cyclohexyl cyclohexenyl sulphide*) were tested, gave an intermediate result, passing to the corresponding thiol but giving no hydrogen sulphide. Thus the C-S bond seems to be attacked by the reducing agent only when the carbon atom is in the α -position to a double bond, or in other words the sulphur atom can be reductively detached from α -methylene groups to which it is linked, but not from saturated carbon chains. The cyclic sulphides from dihydromyrcene and geraniolene gave, as would be expected from the constitutions assigned above, much thiol but no hydrogen sulphide, but reaction was considerably more sluggish, presumably on account of the alkyl substitution at each of the α -methylene groups. For comparison, a compound of the olefin thioepoxide group, *viz.*, thioepoxycyclohexane, was tested: this, in spite of the saturated chain attached on either side to the sulphur atom, underwent ready reduction to a mixture of thiol and hydrogen sulphide.

Instability of Polysulphide Chains.—The ability of sulphur atoms to become linked in chains or groups, and for elementary sulphur to exist normally in closed chains of eight, six, or possibly fewer atoms is commonly regarded as an expression of the strong co-ordinating power of sulphur, and hence there is some expectation that branching of sulphur chains due to co-ordination

(*e.g.*, $\begin{array}{c} \text{S}\cdot\text{S}\cdot\text{S}\cdot\text{S}\cdot \\ \downarrow\downarrow \\ \text{S}\quad\text{S} \end{array}$) may frequently occur. The high-molecular polysulphides formed by the polymeric

interaction of organic dihalides and sodium tetrasulphide (Patrick, *Trans. Faraday Soc.*, 1936, 32, 347) are reported to contain co-ordinated sulphur atoms in their polysulphide groups, since a proportion of the sulphur can be easily removed by caustic alkali. It is reasonable to suppose that the alleged co-ordinated structure is derived directly from the tetrasulphide reagent, and that corresponding syntheses starting out from normal-chained polysulpho-reagents will yield unco-ordinated polysulphides which will not be "stripped" by caustic alkali (*cf.* Patrick, *loc. cit.*) or by sodium sulphite (*cf.* Parker, *India Rubber J.*, 1945, 108, 387). A study of polysulphide constitution and instability will appear in a later part of this series; therefore it suffices now to point out that in our experiments the removal of sulphur by caustic alkali or sodium sulphite succeeds with the above-described products of the olefin-sulphur reaction *only* to the extent of a few units %, suggesting that the sulphur chains are almost wholly unbranched; in contrast to this, however, the diethyl tetrasulphide derived from sulphur monochloride, usually believed to be $\text{Cl}\cdot\text{S}\cdot\text{S}\cdot\text{Cl}$, and ethylthiol ($\text{Cl}\cdot\text{S}_2\cdot\text{Cl} + 2\text{Et}\cdot\text{SH} \longrightarrow \text{Et}\cdot\text{S}\cdot\text{S}_2\cdot\text{S}\cdot\text{Et} + 2\text{HCl}$), as also that derived by the interaction of sodium tetrasulphide which according to the foregoing indications is branched, and ethyl iodide, surrenders nearly half its sulphur to the stripping agent. Hence there is no certainty that sulphur removed by mild stripping agents is necessarily co-ordinated sulphur, or that straight sulphur chains cannot often be ruptured and deprived of part of their sulphur by the same means.

All di- and poly-sulphides formed in the olefin-sulphur reaction decompose progressively at temperatures above 140° (especially from 160° upwards) into hydrogen sulphide, thiol, and monosulphide, but when temperatures above 140° are avoided in the working up of the products comparatively little monosulphide (with some olefins, none at all) and only traces of hydrogen sulphide are formed. Therefore the formation of a large proportion of monosulphide in any olefin-sulphur reaction is fairly safely to be attributed to secondary action, *i.e.*, to thermal decomposition of primary polysulphides due to too long heating or too high temperatures; apparently, however, some monosulphide is produced as a primary product, and there is no

evidence as yet to suggest that the cyclic monosulphides from the di-isoprenes are other than primary products, although thermal decomposition of polysulphides may well be able to produce additional amounts. The amount of thiol formed in the thermal decomposition of the polysulphides from cyclohexene (as also those from 1-methylcyclohexene) is comparatively large, being formed apparently by progressive breaking of the S-S-S- chains, followed by capture of hydrogen atoms from surrounding olefinic molecules ($R-S-S-S-SR' \rightarrow R-S^*$ or $R'-S^* \rightarrow R-SH$ or $R'-SH$). Experiment, indeed, showed that when a polysulphide mixture was distilled above the decomposition temperature, the later distillate fractions showed a H/C ratio progressively smaller and smaller until finally a solid residue containing 39.5% of sulphur but only 3.75% of hydrogen (H/C = 6:4.75) was left. The thiol formed by degradation appears always to be partly olefinic. Disproportionation of the sulphur content doubtless normally accompanies thiol formation when the sulphur chain is severed; Hinsberg (*Ber.*, 1910, 43, 1874) early observed that aromatic disulphides yielded monosulphide and trisulphide as well as some thiol; and other similar instances are on record.

The Sulphur Reagent and the Initiation of Reaction.—It is provisionally concluded from the foregoing that the ordinary reaction form of sulphur in the rather slow sulphur-olefin reactions is the open, radical-terminated sulphur chain, and consequently that in the formation of the cyclic monosulphides the first step may still possibly consist in the union of one end of such sulphur chain with an olefin molecule, later to be followed by rupture of the sulphur chain ($>C-S-S-S- \rightarrow >C-S- + -S-S-S-$). The preceding results provide some ground for believing that α -methylene initiating attack by the sulphur reagent predominates over additive attack. A difficulty, however, arises in connexion with the latter view, which is left for future resolution, *viz.*, that there is a very sharp contrast between the relatively facile carbon-to-carbon molecule-linking action of peroxidic oxygen, *i.e.*, of the free radicals such as $\cdot OH$ derived from decomposing peroxides, ($2C_6H_{10} + 2\cdot OH \rightarrow C_6H_9\cdot C_6H_9 + 2H_2O$) and the inefficient, but not unknown, similar cross-linking action of sulphur or sulphuro-radicals. This seems to suggest that the appearance of radical centres on α -methylene carbon atoms either occurs relatively rarely in sulphur-olefin reactions or else such centres do not ordinarily get beyond the influence of the reacting sulphur.

EXPERIMENTAL.

(Analyses are by Dr. W. T. Chambers and Miss H. Rhodes.)

Action of Sulphur on cycloHexene.—cycloHexene (88 g.) and sulphur (25 g.) were heated together in a rotating steel autoclave for *ca.* 5 hours. A portion of the liquid product was shaken repeatedly with cold dilute potassium hydroxide solution, and the combined washings acidified with hydrochloric acid and then extracted with ether. The ethereal extract gave no appreciable residue (a smell only) of thiol on evaporation; therefore the total neutral product after being carefully freed from the unchanged cyclohexene by distillation was directly fractionated. The dark brown viscous liquid was first heated at 0.1 mm. pressure (the heating bath being kept below 140°), whereupon a nearly colourless oil (4 g.), b. p. 70–100°, distilled. This was re-fractionated, giving (i) a monosulphide, b. p. 70° (*ca.* 0.5 g.) and (ii) a disulphide of b. p. 106° (*ca.* 3.4 g.). The monosulphide was a mixture of unsaturated and saturated forms (Found: C, 72.9; H, 10.5; S, 16.4; H:C = 10.2:6. Calc. for $C_{12}H_{20}S$: C, 73.4; H, 10.3; S, 16.35%; H:C = 10:6. Calc. for $C_{12}H_{22}S$: C, 76.65; H, 11.15; S, 16.2%; H:C = 11:6), containing some dicyclohexyl sulphide since it gave with methyl iodide a poor yield of dicyclohexylmethylsulphonium iodide, m. p. 110.5° (mixed m. p. with authentic specimen derived from pure dicyclohexyl sulphide, 110.5°) Meyer and Hohenemser (*loc. cit.*) had shown that less cautious heating of the total sulphuration product gave a much higher yield than that here obtained of a comparable monosulphide which was thought to consist wholly or mainly of dicyclohexyl sulphide, since it gave with methyl iodide the above mentioned sulphonium iodide, m. p. 110.5°. The disulphide, also, was partly unsaturated (Found: C, 63.4; H, 9.05; S, 27.5; H:C = 10.5:6. $C_{12}H_{20}S_2$ requires C, 63.1; H, 8.8; S, 28.05%. $C_{12}H_{22}S_2$ requires C, 62.6; H, 9.65; S, 27.8%).

The viscous residue in the still was transferred to a "molecular" still and further fractionated. In this operation a Waterman (vertical-type) still gave poor results owing to unavoidable "channeling" of the distilland on the heating surface due to low wetting-capacity for glass: hence a pot-still operating at *ca.* 10⁻⁶ mm. was used in preference. Numerous fractions of increasing sulphur content were successively collected, including two fractions both showing unsaturation, consisting respectively of a *tri*- and a *tetra*-sulphide. The trisulphide, $n_D^{18} 1.5884$, was a thick, pale yellow liquid (Found: C, 55.6; H, 7.95; S, 36.4; H:C = 10.2:6. $C_{12}H_{20}S_3$ requires C, 55.3; H, 7.75; S, 36.95%. $C_{12}H_{22}S_3$ requires C, 54.9; H, 8.45; S, 36.65%), and the tetrasulphide, a still more viscous yellow liquid (Found: C, 49.7; H, 6.95; S, 43.15; H:C = 10.0:6. $C_{12}H_{20}S_4$ requires C, 49.3; H, 6.9; S, 43.8%; the latter had $n_D^{18} 1.6130$, $d_4^{25} 1.209$, $[R_L]_D 84.20$ (Calc. for $C_6H_{11}\cdot S_4\cdot C_6H_{11}$, using Twiss's refractivity value for the sulphur of disulphides: 85.15).

The final residue in the still (*ca.* 34 g.) was a very dark, viscous liquid, varying a little in composition from experiment to experiment. Typical analytical values were: C, 40.95; H, 6.75; S, 53.45; H:C = 10.05:6. (Calc. for $C_{12}H_{20}S_5$: C, 40.45; H, 5.65; S, 53.9%). The separation of a pentasulphide from this residue by further distillation could be effected only with difficulty and incompletely. One such crude product, a reddish oil, had S, 52.9% (Calc.: S, 53.9%).

The recovered cyclohexene was examined spectroscopically in U.V. light, by Dr. H. P. Koch. Less than 1% of benzene and an almost negligible amount of cyclohexadiene were found to be present.

Several further reactions between cyclohexene and sulphur were carried out as above, diminishing proportions of sulphur being used (down to 0.18 atom per mol.). The sulphurated products were in all cases quantitatively similar to the foregoing, but the total yield diminished with reduction in the amount of sulphur employed.

Action of Sulphur on 1-Methylcyclohexene.—The hydrocarbon (30 g.) and sulphur (7 g.) were heated in a sealed tube at 140–145° for ca. 6 hrs. The unchanged hydrocarbon (15 g.) was distilled off through a column, leaving a rather thick brown liquid, from a sample of which repeated vigorous agitation with aqueous sodium hydroxide extracted no thiol. Distillation at 0.1 mm. (bath below 145°) gave only a very small amount (too small for refractionation) of crude monosulphide, contaminated with hydrocarbon (Found: S, 12.2. $C_{11}H_{18}S$ requires S, 14.3%). Continuation of the distillation at 10⁻⁶ mm. gave a succession of fractions of increasing viscosity and deepening yellow colour corresponding respectively to disulphide $C_7H_{11}S_2 \cdot C_7H_{13}$ (Found: C, 65.0; H, 9.55; S, 25.3; H:C = 12.25:7. $C_{14}H_{24}S_2$ requires C, 65.6; H, 9.45; S, 25.0%), trisulphide, $C_7H_{11}S_3 \cdot C_7H_{13}$ (Found: C, 57.85; H, 8.4; S, 34.0; H:C = 12.1:7. $C_{14}H_{24}S_3$ requires C, 58.25; H, 8.4; S, 33.35%), and a tetrasulphide, $C_7H_{11}S_4 \cdot C_7H_{13}$ (Found: C, 52.25; H, 7.7; S, 39.85%; H:C = 12.3:7. $C_{14}H_{24}S_4$ requires C, 52.45; H, 7.55; S, 40.0%). The pentasulphide, which distilled with great difficulty, was not completely isolated, or wholly freed from residual tetrasulphide. The crude fraction formed a dark reddish oil (Found: C, 49.6; H, 7.5; S, 43.1. $C_{14}H_{24}S_5$ requires C, 47.6; H, 6.85; S, 43.1%).

Action of Sulphur on isoButylene.—The liquid hydrocarbon (56 g.; 1 g.-mol.) was introduced at -50° into a steel autoclave which contained sulphur (35 g.; 1.1 g.-mol.). The sealed autoclave was heated at 140–150° for 14 hrs., then strongly cooled and opened. A sample of the liquid contents was tested at once for thiol by Bell and Agruss's test (*Ind. Eng. Chem. Anal.*, 1941, 13, 297); no significant proportion was present. The unreacted isobutylene was allowed to evaporate, and the liquid residue (53.8 g.) distilled. The first distillate was a red liquid, b. p. 80°/12 mm. (21.8 g.), and the second a dark red rather thick liquid, b. p. 90°/0.5 mm.; there remained a dark red very viscous liquid in the still (ca. 14 g.). The first two distillates were separately fractionated and the products refractionated. Although these two stages of rectification did not result in perfect segregation of the individual polysulphides, an approximate separation into di-, tri-, and tetra-sulphides was achieved. The various fractions were yellow, reddish yellow, red and dark red liquids of increasing viscosity. The following analytical data for the fractions (a)–(k) were obtained:—

Fraction, b. p./0.5 mm.	Found, %.			n.	H : C.	Sulphide.
	C.	H.	S.			
(a) Forerun						
(b) 38°	54.5	10.0	34.95	n_D^{20} 1.5005	8.75 : 4	Di-
(c) 38–39°	52.95	9.6	37.0	n_D^{20} 1.5070	8.7 : 4	
(d) 39–40°	—	—	—	—	—	—
(e) 40–44°	—	—	44.5	$n_D^{19.5}$ 1.5292	—	—
(f) 44–51°	—	—	44.7	$n_D^{19.5}$ 1.5330	—	—
(g) 51–60°	44.65	8.2	45.4	$n_D^{19.5}$ 1.5407	8.8 : 4	Tri-
(h) 60–70°	43.65	7.65	47.6	$n_D^{19.5}$ 1.5620	8.4 : 4	—
(i) 70–80°	—	—	—	—	—	—
(j) 80–90°	38.95	6.75	53.6	—	8.26 : 4	Tetra-
(k) Viscous residue	41.3	6.55	51.6	—	7.56 : 4	—

($C_8H_{16}S_2$ requires C, 54.5; H, 9.1; S, 36.35%; $C_8H_{16}S_3$ requires C, 46.1; H, 7.7; S, 46.1%; $C_8H_{16}S_4$ requires C, 40.0; H, 6.75; S, 53.3%.)

It is seen that no definite monosulphide fraction could be isolated and that the ultimate very viscous residue (although doubtless very heterogeneous, and probably containing *inter alia* some triolefinic sulphides derived by double cross-linking) approximated in average composition to tetrasulphide.

Action of Sulphur on Dihydromyrcene.—The hydrocarbon (60 g.) and sulphur (6 g.) were heated at 140° for about 5 hours in a steel rotating autoclave in an atmosphere of nitrogen. The product was a dark red, somewhat viscous liquid, from which unused hydrocarbon (ca. 41 g.) was distilled through a fractionating column at 15 mm. pressure (Found: C, 85.85; H, 12.95; H:C = 18.1:10. Calc. for $C_{10}H_{16}$: C, 86.85; H, 6.65%).

About half the remaining liquid (10 g.), which yielded no significant thiol fraction when thoroughly extracted with sodium hydroxide solution, was volatile at 15 mm. (b. p. 90–92°; n_D^{20} 1.4966). This product, a monosulphide of dihydromyrcene, could not be completely freed from the last traces of hydrocarbon by repeated fractionation under a good column; the sulphur content was accordingly unavoidably low (Found: C, 70.85; H, 10.7; S, 18.4; active H, 0.02. $C_{10}H_{16}S$ requires C, 70.5; H, 10.65; S, 18.85; active H, 0.0%). This monosulphide was necessarily of cyclic constitution but improbably structurally homogeneous (see p. 1523); it gave (but only in part) with methyl iodide a methiodide, m. p. 130° (decomp.) (Found: S, 10.0; I, 40.5. $C_{11}H_{21}SI$ requires S, 10.25; I, 40.65%).

The undistilled sulphurated residue (ca. 18.5 g.) was a very viscous, dark red oil, easily soluble in hydrocarbons, carbon disulphide, and ethyl alcohol. A separation of this product into two roughly equal parts was effected by extracting it with methyl alcohol. These parts, although fairly reproducible as regards elementary composition, were probably both mixtures of sulphides, since their analyses corresponded with no definite compound. The insoluble fractions obtained in successive separations were dark brown, viscous oils (Found: S, 30.2; 28.1, 28.55%), and the corresponding soluble fractions reddish-brown oils (Found: S, 25.6, 25.1, 24.6%). These materials possessed the same general characteristics as the polysulphides from the simple olefins.

Action of Sulphur on Geraniolene.—The geraniolene (b. p. 109–111°/12 mm.) was prepared from commercial citral, which was first purified by conversion into the corresponding bisulphite compound (see Hibbert and Cannon, *J. Amer. Chem. Soc.*, 1942, **64**, 119), then oxidised to geranic acid (b. p. 118–120°/0.1 mm.; n_D^{20} 1.4880) by means of silver oxide (see Bernhauer and Forster, *J. pr. Chem.*, 1936, **147**, 199), and finally decarboxylated by heating it at ca. 260° in a stream of nitrogen. The crude hydrocarbon, mixed with a little geranic acid, distilled during the decomposition. Several batches of hydrocarbon were united and rectified. The final product was colourless liquid, b. p. 35–36°/15 mm., n_D^{20} 1.4410.

The hydrocarbon (72 g.) was heated with sulphur (7.0 g.) in a steel rotating autoclave for 5 hrs. at 140°. The crude product yielded no thiol fraction when thoroughly extracted with sodium hydroxide solution; it contained, however, much unconsumed hydrocarbon (about $\frac{2}{3}$ of original bulk), which was recovered by distillation.

About half the liquid residue (ca. 14 g.) was distillable at 12 mm. pressure, so giving a colourless, sweet-smelling liquid similar to that obtained from dihydromyrcene and sulphur. This product, n_D^{20} 1.4840, like the dihydromyrcene derivative, retained obstinately in spite of repeated refractionations traces of hydrocarbon. In consequence the sulphur content was invariably slightly low. It boiled at 65.5–66°/12 mm. (Found: C, 69.5; H, 10.5; S, 19.9; active H, 0.02. $C_8H_{14}S$ requires C, 69.2; H, 10.3; S, 20.5; active H, 0.0%).

Desulphuration of Polysulphides.—The method of desulphuration devised by Mazingo *et al.* (*loc. cit.*), employing Raney nickel powder prepared in the recommended way, was followed. The sample of nickel used evolved, on test, 116 c.c. of hydrogen per g. on being heated in butyl phthalate suspension at 220°. The sulphur compound (ca. 6 g.), dissolved in a little freshly-distilled cyclohexane, was dropped into a layer of freshly-distilled cyclohexane which acted as covering for the pyrophoric nickel (ca. 120 g.). Minute bubbles of gas were liberated immediately the sulphide was added. Gentle refluxing of the mixture for 3 hours completed the reaction, whereupon the solvent was removed by careful decantation, the nickel was extracted several times by boiling cyclohexane, and the solvent distilled from the united cyclohexane liquors through a column. The sulphides so treated were dicyclohexenyl sulphide (see below), and specimens of the total sulphuration products (freed from unconsumed hydrocarbon) derived from cyclohexene, 1-methylcyclohexane and isobutylene. In no case did any high-boiling hydrocarbon (representing a di- or poly-molecular derivative of the olefin originally sulphurated) or any sulphide remain.

Synthesis of Sulphides, Polysulphides, etc.—(1) 3:3'-Dicyclohexenyl sulphide. *N*-Bromosuccinimide (73.2 g.), prepared by the method of Ziegler *et al.* (*Annalen*, 1942, **551**, 80), and cyclohexene (206 c.c.) were gently refluxed for 20 mins. in pure carbon tetrachloride (300 c.c.) in the presence of a trace of benzoyl peroxide. Succinimide, which was insoluble in the tetrachloride, was gradually precipitated and was finally filtered off. The solvent was distilled off through a column and the residue fractionated. About 40 g. of almost colourless 3-bromocyclohexene, b. p. 60–61°/15 mm., n_D^{20} 1.5395, were collected (Found: C, 44.85; H, 5.7; Br, 49.3. Calc. for C_6H_9Br : C, 44.75; H, 5.65; Br, 49.6%).

3-Bromocyclohexene (12 g.), powdered sodium sulphide (5 g.), and alcohol (15 c.c.) were sealed in a Carius tube and heated to 100° for 4 hrs. The liquid in the cooled tube was filtered, diluted with ether, washed with water, dried (K_2CO_3), and the ether distilled. The residue, when distilled at ca. 0.1 mm. pressure gave about 4.5 g. of a colourless liquid, b. p. 81–82°, n_D^{20} 1.5506, of not unpleasant smell. This was 3:3'-dicyclohexenyl sulphide (Found: C, 74.15; H, 9.45; S, 16.35. $C_{12}H_{18}S$ requires C, 74.2; H, 9.35; S, 16.35%).

(2) cycloHexyl cyclohexenyl sulphide. This was formed by the action of lead cyclohexyl mercaptide on 3-bromocyclohexene. cycloHexanethiol (20 g.), prepared by the hydrolysis of cyclohexyl thiolacetate with alcoholic potassium hydroxide (Cunneen, *J.*, 1947, 134), was converted into its lead salt by shaking it for some hours in a stoppered vessel with excess of aqueous lead acetate. The precipitated yellow mercaptide was filtered off, well washed, dried at reduced pressure, and then suspended in alcohol (4000 c.c.). To the suspension was added 3-bromocyclohexene (29 g.), and the whole refluxed for 1 hr. on a water-bath. After filtration, most of the alcohol was distilled off through a column, and the concentrated alcoholic residue poured into water and extracted with ether. The extract was washed with water, dried ($CaCl_2$), and distilled. Much unchanged thiol passed over first, and then a colourless liquid, b. p. 69–70°/0.1 mm., n_D^{20} 1.5317, of not unpleasant smell. The latter was cyclohexyl cyclohexenyl sulphide (Found: C, 73.35; H, 10.2; S, 16.15. $C_{12}H_{20}S$ requires C, 73.4; H, 10.25; S, 16.3%).

(3) Propyl allyl sulphide. *n*-Propanethiol (45 g.) was converted into its lead salt as above, and the dried salt suspended in alcohol. To the suspension allyl bromide (70 g.) was added with shaking, and the whole refluxed for 1 hr. The resulting liquor was filtered from insoluble lead salts, poured into water, and extracted with ether. The extract was washed with water, dried ($CaCl_2$), and distilled at atmospheric pressure. The distillate (30 g.), a colourless mobile liquid, b. p. 138–140°/755 mm., was propyl allyl sulphide (Found: C, 61.9; H, 10.4; S, 27.7. $C_6H_{12}S$ requires C, 62.0; H, 10.4; S, 27.55%).

(4) cycloHexene thioepoxide (episulphide). This was obtained by the interaction of 1-chloro-2-thiocyanocyclohexane and sodium sulphide ($C_6H_{10}ClSCN + Na_2S \rightarrow C_6H_{10}S + NaCl + NaSCN$). Lead thiocyanate (235 g.) was dried, placed in a 1-l. flask, and covered with dry carbon tetrachloride (600 c.c.) to which cyclohexene (49 g.) had been added. The mixture was thoroughly stirred while phenyl iododichloride (153 g.) was added in small amounts during about 45 mins., and thereafter for 1 hr. The product was then filtered from insoluble lead salts, shaken with sodium thiosulphate solution to remove free dithiocyanogen, and washed as well as possible with water (the formation of emulsions gave trouble). The carbon tetrachloride solution was dried ($CaCl_2$), filtered from polythiocyanogen, and distilled. The solvent and any iodobenzene formed in the reaction were removed at reduced pressure; the residue, consisting of 1-chloro-2-thiocyanocyclohexane, distilled at 90–92°/0.1 mm. as a colourless liquid, after a forerun of 3 g. had been rejected (Found: C, 47.85; H, 5.8; N, 8.15; S, 18.3; Cl, 19.95. $C_6H_{10}NCIS$ requires C, 47.85; H, 5.75; N, 8.0; S, 18.2; Cl, 20.2%). n_D^{20} 1.5284, $[R]_D^{20}$ 44.86.

The chlorothiocyano-cyclohexane (31 g.) was dissolved in absolute alcohol (120 c.c.), and powdered sodium sulphide (25 g.) added. The mixture, contained in a 250-c.c. flask, was thoroughly stirred and refluxed on a water-bath for 2 hours. The cooled product was poured into water and extracted several

times with ether. The extract was dried (K_2CO_3), filtered, and the solvent distilled. The residue on distillation at 15 mm. pressure gave *cyclohexene thioepoxide* as a colourless mobile oil of distinctive odour, b. p. 56–57°, n_D^{20} 1.5350 (Found: C, 63.05; H, 8.85; S, 27.95. $C_6H_{10}S$ requires C, 63.1; H, 8.8; S, 28.05%).

(5) *Diethyl tetrasulphide*. Sodium tetrasulphide (23 g.), prepared by the method of Rule and Thomas (J., 1914, 105, 777), freshly-distilled ethyl iodide (60 g.), and absolute alcohol (90 c.c.) were refluxed on a water-bath for 2 hours in a slow stream of nitrogen. The product, when cool, was poured into water, and the precipitated oil extracted with benzene. The extract was dried (K_2CO_3), and the benzene distilled off. The oily residue, on distillation at 0.1 mm., passed over mainly at 43–45°, giving an evil-smelling, yellow oil, b. p. 43–45°, n_D^{20} 1.6105. This was undoubtedly slightly impure diethyl tetrasulphide (Found: S, 67.4. Calc. for $C_4H_{10}S_4$: S, 68.8%), which Riding and Thomas (J., 1923, 123, 3271; 1924, 125, 2463), probably owing to the technique adopted, failed to isolate after carrying out the same reaction. A small forerun and a residue, obtained as by-products, may well have represented the corresponding di- and penta-sulphide which were reported by Riding and Thomas to be formed. Comparison of the product with that obtained by the action of sulphur monochloride on ethanethiol (cf. Chakravarti, J., 1923, 123, 966), including spectroscopic examination in U.V. light by Dr. H. P. Koch, disclosed no essential difference between the two, although the latter appears to be freer from impurities (see Part IV).

(6) The following thio-compounds required for comparison with products derived by interaction of olefins and sulphur, and for infra-red spectroscopic observations, were synthesised by methods fully described in the literature: Thiols, ethyl, *n*-butyl, and *cyclohexyl*; sulphides, di-*n*-propyl, di-*n*-butyl, diallyl, dicrotyl; disulphides, di-*n*-butyl, dibenzyl.

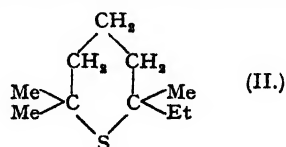

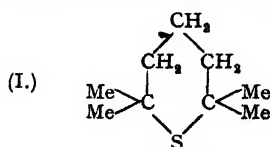

Infra-red Spectra.—The following report on the characteristics of thio-compounds has been furnished by Dr. G. B. M. Sutherland and Mr. N. Sheppard.

(1) *The Products of the sulphur-cyclohexene reaction*. The infra-red spectra of *cyclohexanethiol*, *dicyclohexyl sulphide*, 3 : 3'-*dicyclohexenyl sulphide*, and *cyclohexene episulphide* were compared with a series of ten fractions of the reaction products.

In no case was *cyclohexene episulphide* detectable in the reaction products, and only one of the "monosulphide" fractions showed the presence of *cyclohex-2-enyl* groups, . In most cases

the strong bands in the spectra were nearly all those of *cyclohexyl* groups, showing that such saturated groups predominated, but in addition every sample showed "unsaturation" bands due to C=C valency vibrations between 1590 and 1600 cm^{-1} , which are in the position generally associated with unsaturation of a conjugated type. No other olefinic groups were detected.

(2) *The reaction products of sulphur with geraniolene and dihydromyrcene*. The infra-red spectra of these products were compared with those of the saturated products obtained from the reaction of the same hydrocarbons with hydrogen sulphide (Sheppard and Sutherland, this vol., p. 1540). Two general points were noticeable: (a) Bands at 890 cm^{-1} indicated the presence of double bonds of the type $CRR'CH_2$ in the sulphur products. (b) There was a strong general resemblance in both cases between the spectra of the products of the reaction with sulphur and those with hydrogen sulphide. In the case of the geraniolene-sulphur product a noticeable splitting of the 1370 cm^{-1} band indicated a preponderance of *gem*-dimethyl groups (Sheppard and Sutherland, *loc. cit.*), and was further evidence for the similarity of the two products (see below). As the purification of the hydrogen sulphide products led to their identification as 2 : 2 : 6 : 6-tetramethyltetrahydrothiopyran (I) and 2 : 2 : 6-trimethyl-6-ethyltetrahydrothiopyran (II), it seems reasonable to assume that the carbon skeletons of the sulphur products

are closely related. On chemical grounds one would expect that the sulphur products would contain a double bond in the molecule, but our spectroscopic data are insufficient to decide this point. However, in view of the fact that the spectra of *cyclohexyl* and *cyclohexenyl* groups have many features in common, the spectroscopic data would be consistent with the presence of the above saturated compounds in the products or, alternatively, with the presence of similar compounds containing a double bond in the ring. Since $CRR'CH_2$ groups are not obtainable with carbon skeletons of the above type, these bands presumably arise from another molecular species in the product.

Reductive Scission of Sulphides.—(a) *Action on saturated dialkyl sulphides*. Redistilled di-*n*-butyl sulphide (1 g.; 1 mol.) was dissolved in absolute alcohol (50 c.c.), and sodium (5 g.; 3.2 atoms) added in portions. The alcohol was kept boiling until the sodium had all dissolved, whereupon the product was cooled, poured into water, and the aqueous liquor extracted once with ether to remove traces of unchanged sulphide. The alkaline liquor was then acidified with hydrochloric acid and several times extracted with ether to remove all thiol formed in the reduction. The ethereal extract was freed from traces of mineral acid by washing it with water, and afterwards the content of thiol determined by means of silver nitrate following the procedure of Bell and Agruss (*loc. cit.*). It was found that no appreciable reduction of sulphide to thiol had occurred. The experiment was repeated with pure di-*n*-propyl sulphide, with the same result.

(b) *Action on dialkenyl sulphides*. This was examined with diallyl and *dicyclohexenyl* sulphides. The amount of hydrogen sulphide and thiol (respectively) produced by reaction were determined from the total yield of -SH groups (including hydrogen sulphide) and the yield of thiol. These values were determined by extracting the hydrogen sulphide and thiol together from one aliquot part of the acidified (H_2SO_4), sulphide-free reduction liquor by means of benzene, and precipitating the hydrogen sulphide

from another by means of cadmium chloride, before extracting the thiol from the filtered liquor by means of ether. The details were essentially those of Bell and Agruss (*loc. cit.*). Diallyl sulphide (0.20 g.) became completely reduced, giving approximately equimolecular amounts of hydrogen sulphide (0.0260 g.) and thiol (0.062 g., calc. as allylthiol). Dicyclohexenyl sulphide (0.33 g.) was similarly completely reduced, giving hydrogen sulphide (0.024 g.) and thiol (0.13 g., calc. as cyclohexenthiol).

(c) *Action on alkyl alkenyl sulphides.* These sulphides gave no hydrogen sulphide on reduction, which was incomplete. cyclohexyl cyclohexenyl sulphide (0.26 g.) gave thiol (doubtless cyclohexyl, 0.091 g.; corresponding to ca. 60% reduction); propyl allyl sulphide (0.105 g.) gave thiol (doubtless propyl, 0.033 g., corresponding to ca. 50% reduction).

(d) *Action on cyclic sulphides.* The cyclic sulphides from dihydromyrcene and geraniolene were separately reduced in the usual way. Reduction proved to be very incomplete in each case; no hydrogen sulphide was produced but a moderate yield of alkali-soluble thiol was formed from each sulphide.

(e) *Action on thioepoxides.* This was examined only in the instance of cyclohexene thioepoxide. The latter (0.148 g.) gave both hydrogen sulphide (0.010 g.) and thiol (doubtless cyclohexyl, 0.08 g.).

Action of methyl iodide on monosulphides. The sulphide was in each case mixed with an equal volume of the reagent and kept in the dark overnight. A typical saturated sulphide, dicyclohexyl sulphide, gave in good yield the corresponding sulphonium iodide, $\text{SMe}(\text{C}_6\text{H}_{11})_2\text{I}$, m. p. 111°. Three dialkenyl sulphides, viz., diallyl, dicrotyl, and 3 : 3'-dicyclohexenyl sulphide, all readily gave crystals of trimethylsulphonium iodide, m. p. 204–207° (decomp.), identical with the compound prepared by union of methyl iodide and methyl sulphide, but no stable sulphonium compound. Two alkyl alkenyl sulphides, viz., cyclohexyl cyclohexenyl sulphide and propyl allyl sulphide, both gave non-crystallising oily products.

The monosulphide from the cyclohexene-sulphur reaction gave much oily material, like the alkyl sulphides, but also a little dicyclohexylmethylsulphonium iodide, m. p. 110° (mixed with authentic specimen, 110°). The cyclic sulphide from dihydromyrcene gave with methyl iodide an oil which slowly crystallised: the resulting solid (colourless prisms, m. p. 130°, from ether-alcohol) was a *methiodide* of dihydromyrcene monosulphide (Found: C, 42.0; H, 7.0; I, 40.5. $\text{C}_{11}\text{H}_{21}\text{SI}$ requires C, 42.3; H, 6.8; I, 40.65%). The cyclic sulphide from geraniolene likewise gave with methyl iodide an oil that slowly crystallised: the solid (colourless prisms, m. p. 120°, from ether-alcohol) was a *methiodide* of geraniolene monosulphide (Found: C, 39.9; H, 6.85; I, 42.25; S, 10.45. $\text{C}_{10}\text{H}_{19}\text{SI}$ requires C, 40.25; H, 6.45; I, 42.55; S, 10.75%).

cyclohexene episulphide gave with methyl iodide in a few hours much trimethylsulphonium iodide, m. p. 204–207° (Found: C, 17.55; H, 4.45. Calc. for $\text{C}_3\text{H}_5\text{SI}$: C, 17.7; H, 4.45%).

Removal of Polysulphide Sulphur by Chemical Reagents.—(a) *With sodium hydroxide.* The sample of sulphide was placed in a small flask (ca. 10 c.c.) together with 10% or 40% alkali (6 c.c.) and a few c.c. of 0.1% sodium stearate to act as wetting agent. The air space was filled with nitrogen, and the closed vessel mechanically shaken in an oil-bath adjusted to the desired temperature. After the period of treatment was completed the reaction liquor was poured into water, the oily sulphide extracted with benzene, the benzene solution washed well with water and dried (K_2CO_3), and the dry solution filtered and freed from solvent in a vacuum without heating. The decrease in sulphur content due to the action of the alkali was determined by analysis of the specimen before and after treatment in preference to determining the amount of sulphide formed in the reaction.

Typical examples of the effect of the alkali in removing sulphur are the following: The tetrasulphide from cyclohexene decreased in sulphur content from 43.15 to 41.0% in 3 hrs. at 60° with 10% alkali, and from 43.15 to 40.15% in 3 hours at 80° with 40% alkali. The tetrasulphide from cyclohexene decreased in sulphur content from 36.4 to 33.65% in 3 hrs. at 80° with 40% alkali. Diethyl tetrasulphide (from sodium tetrasulphide and ethyl iodide) decreased in sulphur content from 67.4 to 51.5% in 3 hrs. at 80° with sodium hydroxide, so giving nearly pure diethyl disulphide (S, 52.5%).

(b) *With sodium sulphite.* The weighed sample of sulphide (usually ca. 0.1 g.) was placed in 10% "AnalaR" sodium sulphite solution (100 c.c.) together with 0.1% sodium stearate (ca. 5 c.c.) to act as wetting agent. The solution was boiled for 2.5 hrs. during which nitrogen was slowly bubbled through. Organic matter was extracted with chloroform; then the aqueous phase was cooled at 0°, and 40% formaldehyde solution added to combine with the excess of sodium sulphite. Glacial acetic acid (10 c.c.) and 1% starch solution (3 c.c.) were next added, and the solution titrated with N/10-iodine solution to determine the yield of sodium thiosulphate and hence the amount of sulphur removed (1 mol. of $\text{Na}_2\text{S}_2\text{O}_3 \equiv 1$ atom of S). The following are typical results, losses being given in terms of total sulphur: Ethyl tetrasulphide (from sodium tetrasulphide and ethyl iodide) lost 47.5% (i.e., 1.9 atoms). The polysulphide mixture (excluding cyclic monosulphide) obtained in the geraniolene-sulphur reaction lost 10.8%. The corresponding polysulphide mixture from dihydromyrcene lost 6.4%. Dibutyl tetrasulphide lost 30.1%, and cyclohexene episulphide 45%.

Thermal Decomposition of Polysulphides.—Attempted distillation at ca. 0.1 mm. of the sulphurated products from cyclohexene and 1-methylcyclohexene gave but little distillate (a little monosulphide and no thiol or hydrogen sulphide) unless the temperature of the heating bath was allowed to rise well above 140°. Prolonged heating at higher temperatures caused a slow but progressive distillation of monosulphide, thiol, and hydrogen sulphide. The tendency to decomposition of the monosulphide-free sulphurated product from cyclohexene was examined at 160–170° by heating it in sealed tubes for 5 hours. The tubes were cooled in liquid air before being opened, and the main bulk of hydrogen sulphide present was allowed to evaporate slowly into lead acetate solution. The lead sulphide was filtered off, dried, and weighed. The thiol and residual hydrogen sulphide were estimated by utilising the method of Bell and Agruss (*loc. cit.*). In a typical experiment 13 g. of the sulphuration product yielded hydrogen sulphide (3.8 g.), thiol (2.5 g.), volatile sulphides (mainly monosulphide, 3.3 g.), and a small amount of non-volatile solid which was easily soluble in benzene (3.2 g.). In another experiment 5.9 g. of thio-product, after being kept at 130° and 10⁻³ mm. for 30 hrs. to ensure that no free thiol or lower sulphides were present, gave, on being heated in a sealed tube at 180–190° for 5 hrs., hydrogen sulphide (1.7 g.), thiol (1.2 g.), sulphides (mainly mono-, 1.4 g.), and a dark residue of solid (mainly crystalline) thiohydrocarbon (1.4 g.). The residue, like all residues similarly obtained by the thermal decomposition of

sulphurated cyclohexene, had a much reduced H:C ratio (Found: C, 56.35; H, 3.75; S, 39.7%; H:C = 4.75/6).

299. *The Reaction of Sulphur and Sulphur Compounds with Olefinic Substances. Part II. Mechanism of the Reaction of Hydrogen Sulphide with Mono-olefins, Di-isoprenes, and Rubber.*

By RALPH F. NAYLOR.

Hydrogen sulphide unites with mono- and di-olefins under pressure to give *normal* adducts when reaction is conducted in the presence of sulphur or a metallic sulphide as catalyst, and *abnormal* adducts when it is promoted under the influence of ultra-violet light. The adducts of both types include alkanethiols and alkyl sulphides and disulphides. The principal reaction products from the two di-isoprenes, dihydromyrcene and geraniolene, are cyclic sulphides of the tetrahydrothiopyran series, each being derived from a single molecule of the diolefin; corresponding products derived from two molecules of the diolefin are formed in much smaller yield. Rubber also gives sulphides of the latter (cross-linked) kind, formed by the linking of two or more polyolefin molecules by sulphur.

APART from the intrinsic interest of the reactivity of hydrogen sulphide with olefins, a knowledge of this reactivity is, as indicated in Part I (preceding paper), of considerable importance in the study of the reaction of sulphur with unsaturated compounds. In marked contrast to the wealth of literature on the addition of hydrogen bromide to olefins, there is very little work recorded on the corresponding reactions of hydrogen sulphide. Such accounts as are published indicate that the addition of hydrogen sulphide is difficult to effect, and that catalysts are invariably required. Among the various catalysts found to be effective are silica gel (Mailhe and Renaudie, *Compt. rend.*, 1932, **195**, 391), nickel on kieselguhr, and certain nickel salts (Duffey, Snow, and Keyes, *Ind. Eng. Chem.*, 1934, **26**, 91; Barr and Keyes, *ibid.*, p. 1111), iron oxide and sulphide (Boëseken and Van der Linde, *Rec. Trav. chim.*, 1935, **54**, 739), and sulphur (Jones and Reid, *J. Amer. Chem. Soc.*, 1938, **60**, 2452). The yields of addition products have seldom been high, and the direction of addition has been found in each case to follow the Markownikow rule, although a proportion of *abnormal* addition products was obtained in high-temperature heterogeneous reactions (Barr and Keyes, *loc. cit.*); this probably arose by partial isomerisation of the initial adduct. Recently, however, Vaughan and Rust (*J. Org. Chem.*, 1942, **7**, 472), by ultra-violet irradiation of mixtures of olefins and liquid hydrogen sulphide, have obtained *abnormal* adducts in a short reaction time, without the aid of the high temperatures and pressures found necessary for *normal* addition.

Since it was observed by Jones and Reid (*loc. cit.*) that the normal addition of hydrogen sulphide proceeds far less readily with cyclohexene than with simple aliphatic olefins, it was not surprising to find that photo-addition of liquid hydrogen sulphide to 1-methylcyclohexene gave poor yields. As Pyrex glass, which was used for the reaction tubes, does not transmit light below 2900 Å., whereas hydrogen sulphide is split into radicals only by wave-lengths of 2800 Å. or less, it was necessary to add acetone as a photo-sensitiser. The products were a thiol and sulphide, and by analogy with the work of Vaughan and Rust, it may be assumed that these were 1-methylcyclohexane-2-thiol (I), and di-2-methylcyclohexyl sulphide (II). In one experiment the sulphide fraction was found to contain some disulphide (III), which although present in insufficient quantity for separation, was indicated to be present by analytical evidence. Although no previous reference has been made to the formation of disulphides in such reactions,

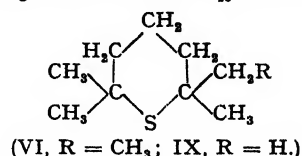

it seems evident that it has arisen either by combination of two mercapto-radicals or by oxidation of the initially formed thiol.

The only recorded work on the catalysis of hydrogen sulphide addition by sulphur (Jones and Reid, *loc. cit.*) suggests that the latter is one of the best catalysts for normal addition, but the relatively large quantities of catalyst then used introduce doubt as to how far the sulphur is itself reacting with the olefins and how far catalysing the addition of hydrogen sulphide. In addition, this work was conducted at 180°, at which temperature there is appreciable decomposition of some di- and poly-sulphides (see Part I; also Hinsberg, *Ber.*, 1910, 43, 1874). It has now been confirmed that small quantities of sulphur catalyse the addition of hydrogen sulphide to isobutylene at ca. 140°; some reaction took place in absence of sulphur, but this was probably due to the catalytic effect of ferrous sulphide formed on the walls of the steel autoclave used. The reaction products were identified as being *tert.*-butyl derivatives formed by "normal" addition of the reagent to the double bond, and included di-*tert.*-butyl disulphide as well as the corresponding monosulphide and thiol. The yield of disulphide was greater than could have arisen by reaction of the sulphur catalyst with isobutylene, and it was still formed when the catalyst was omitted. The possibility of oxidation of the initially formed thiol was investigated by heating *tert.*-butanethiol with air in a sealed tube; no disulphide could be detected although there was some decomposition of the thiol into *tert.*-dibutyl sulphide and hydrogen sulphide. Rigorous exclusion of air from the isobutylene-hydrogen sulphide reaction mixture did not prevent formation of the disulphide, so the only possible mode of reaction seems to be oxidation of the thiol with concurrent reduction (hydrogenation) of the olefin, as reported by Williams and Allen (U.S.P. 2,052,268; *Chem. Abs.*, 1936, 30, 7122) for similar hydrogen sulphide additions.

*cyclo*Hexene reacted with hydrogen sulphide in presence of a sulphur catalyst in a manner analogous to isobutylene, although the *cyclo*hexanethiol first produced appeared to add more readily than hydrogen sulphide to the olefin, since dicyclohexyl sulphide constituted the main product. An attempt to catalyse the addition of hydrogen sulphide to 1-methylcyclohexene by ethyl dihydrogen phosphate, after the suggestion of Bähr and Corr (D.R.-P. 708,261), was unsuccessful.

Sulphur-catalysed addition of hydrogen sulphide to polyisoprenes occurred more readily than it did to hydroaromatic hydrocarbons. Dihydromyrcene, $\text{CH}_3\cdot\text{CMe}\cdot\text{CH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CMe}\cdot\text{CHMe}$, reacted to give a quantity of alkali-soluble material which was too small to permit of isolation of this thiol, but gave a 20% yield of an alkali-insoluble compound of formula $\text{C}_{16}\text{H}_{20}\text{S}$. Of the possible structural formulæ, (IV), (V), and (VI), assignable to this product, (VI), which is formed from (IV) or (V) by an intramolecular addition reaction, seemed the most likely in view of the insolubility of the product in alkali. Inter-molecular addition reaction yielding products containing more than one C_{10} -unit occurred

to the extent of only 1–2%, but there appeared to be some unimolecular disulphide ($\text{C}_{10}\text{H}_{20}\text{S}_2$), which was present in insufficient quantity for isolation. Similar results were obtained by interaction of geraniolene, $\text{CH}_3\cdot\text{CMe}\cdot\text{CH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CMe}\cdot\text{CH}_2$, with hydrogen sulphide, the main product in this case being a thio-compound $\text{C}_9\text{H}_{18}\text{S}$, represented by (VII), (VIII), or (IX). Attempts to obtain characteristic metallic salts or metallic-salt addition compounds were unsuccessful. The infra-red absorption spectrum of this thio-compound was radically different from that of the parent geraniolene, suggesting that a complete change of structure, such as is involved in the formation of a tetrahydrothiopyran ring, might have occurred. An attempt to establish this ring structure by correlation of the spectrum with that of pentamethylene sulphide was unsuccessful, as the latter exhibited an altogether different spectrum from that of the hydrogen sulphide reaction products. Synthetic 2 : 2 : 6 : 6-tetramethyltetrahydrothiopyran (see this vol., p. 1106), although analytically identical with the hydrogen sulphide reaction product, showed differences in boiling point and refractive index, and had a characteristic infra-red absorption spectrum,* which could not be correlated with that of the reaction products. In particular, the latter exhibited absorption associated with unsaturated groupings of the types $\text{CMeR}\cdot\text{CH}_2$ and $\text{CRR}\cdot\text{CHR}$ and with thiol groups.

* Examination of the infra-red absorption spectra of the compounds described in this paper was carried out at Cambridge by Dr. G. B. M. Sutherland and Mr. N. Sheppard. The details of the spectra are discussed by these authors in the following paper.

Similar results were obtained with the dihydromyrcene-hydrogen sulphide product. The possibility of the unsaturation being due to the presence of small amounts of unchanged olefin was excluded by two experiments. Dihydromyrcene is a mixture of 2:6-dimethylocta-2:6-diene, 2:6-dimethylocta-2:6(10)-diene, and possibly 2:6-dimethylocta-1:6-diene and therefore shows absorption characteristic of $\text{CMeR}'\text{CH}_2$ grouping. The pure 2:6-isomer (which exhibits no such absorption) was prepared by sodium-ammonia reduction of geraniol (Chablay, *Ann. Chim.*, 1917, 8, 145; Dupont, Dulou, and Desreux, *Bull. Soc. chim.*, 1939, 6, 84) and reacted with hydrogen sulphide in the presence of sulphur. The resulting product also showed bands characteristic of $\text{CMeR}'\text{CH}_2$ groups, although it was established that no isomerisation of the recovered hydrocarbon had occurred. Also, examination of suitable mixtures showed that introduction of small amounts of dihydromyrcene to the synthetic thiopyran (IX) did not affect the absorption spectrum.

Substitution of aluminium sulphide for sulphur as a catalyst in the reaction of 2:6-dimethylocta-2:6-diene with hydrogen sulphide gave rise to products similar to the foregoing, but there was isolated in addition, 2:6-dimercapto-2:6-dimethyloctane, $\text{CMe}_2(\text{SH})\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CMe}_2\cdot\text{SH}$ (X). The main product, $\text{C}_{10}\text{H}_{20}\text{S}$, showed considerable difference in the absorption attributable to unsaturation from that described above, the predominant group now being $\text{CRR}'\text{CHR}''$ with very little $\text{CMeR}'\text{CH}_2$. It is evident, therefore, that the $\text{CMeR}'\text{CH}_2$ group arises by reaction of the sulphur itself and not of the hydrogen sulphide. That cyclic sulphides containing this group are in fact among the products of reaction of sulphur with dihydromyrcene has been indicated in Part I (*loc. cit.*).

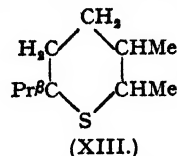

The improbability of the occurrence in significant degree of a radical mechanism leading to "abnormal" addition in the sulphur-catalysed or metal sulphide-catalysed hydrogen sulphide reaction was indicated by demonstrating that the type of reaction obtained with 2:6-dimethylocta-2:6-diene was unaffected by the presence of quinol (polyisoprenes usually contain small quantities of peroxide which might catalyse the abnormal addition). However, the ratio of thiol to cyclic sulphides was increased.

In spite of the alkali-insolubility of the compounds $\text{C}_{10}\text{H}_{20}\text{S}$ and $\text{C}_9\text{H}_{18}\text{S}$, Zerewitinoff determinations by the micro-method of Bolland (*Trans. Inst. Rubber Ind.*, 1941, 16, 267) indicated the presence of varying amounts of active hydrogen, presumably in the form of thiol groups* as had already been indicated by the infra-red spectra. The susceptibility of this method to traces of compounds of low molecular weight containing active hydrogen rendered it less reliable than the method recently described by Turk and Reid (*Ind. Eng. Chem. Anal.*, 1945, 17, 713) involving titration of a solution of the thiol against a solution of cupric butyl phthalate. The presence of the thiols (IV) and (V), and (VII) and (VIII), in amounts up to 40% of the total $\text{C}_{10}\text{H}_{20}\text{S}$ and $\text{C}_9\text{H}_{18}\text{S}$ fractions was thus demonstrated. A modification of the analytical method allowed cupric butyl phthalate to be used for the qualitative removal of the thiol from the mixtures obtained by the aluminium sulphide-catalysed reactions, and this resulted in the isolation in a nearly pure state of 2:2:6-trimethyl-6-ethyltetrahydrothiopyran (VI) and 2:2:6:6-tetramethyltetrahydrothiopyran (IX) (see this vol., p. 1106). These two compounds exhibited absorption spectra similar to each other in the infra-red, and in both, all bands associated with unsaturation and thiol groups had disappeared. The geraniolene-hydrogen sulphide product (IX) corresponded in boiling point with the synthetic 2:2:6:6-tetramethyltetrahydrothiopyran and exhibited similar absorption [notably that associated with the >CMe_2 group which is masked in (VI) by single methyl groups] with the addition of some other absorption bands. These extra bands are almost certainly due to reaction products of small amounts of isomers of geraniolene, for, since the preparation of this involves decarboxylation of geranic acid at 270° , a partial isomerisation of the olefin is very probable. This view is confirmed by the nitrous acid test for thiols (Rheinboldt, *Ber.*, 1926, 59, 1311; 1927, 60, 184), which indicates that while all the dihydromyrcene products contain only tertiary thiols, those from geraniolene contain at least some primary or secondary thiols. Complete agreement was obtained between the infra-red spectrum of the cyclic sulphide from the reaction of 2:6-dimethylocta-2:6-diene and hydrogen sulphide and that of synthetic 2:2:6-trimethyl-6-ethyltetrahydrothiopyran (see this vol., p. 1106).

The abnormal addition of hydrogen sulphide to 2:6-dimethylocta-2:6-diene has been effected by U.V. irradiation of the reactants in the liquid phase, acetone being used as a photo-sensitiser. As in other additions, the main product was a liquid of formula $\text{C}_{10}\text{H}_{20}\text{S}$, which was shown to consist of an approximately 1:1 mixture of the monothiols (XI, XII) and

* It is known from earlier work that the acidity of thiols decreases progressively with increasing molecular weight (Birch and Norris, *J.*, 1925, 127, 901).

2 : 3-dimethyl-6-isopropyltetrahydrothiopyran (XIII). Removal of the thiol by cupric butyl phthalate led to the isolation of a small quantity of the thiopyran (XIII), the absorption

spectrum of which exhibited a number of differences from those of the earlier products. In particular, there was some characteristic absorption which was absent in the *normal* adduct (VI), and *vice versa*. Similar differences in the absorption spectrum were exhibited by 3 : 7-dimercapto-2 : 6-dimethyloctane, $\text{CHMe}_2\cdot\text{CH}(\text{SH})\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CHMe}\cdot\text{CHMe}\cdot\text{SH}$ (XIV), which was also isolated in small yield from the reaction product.

In addition, an intermolecularly derived *sulphide*, $\text{C}_{20}\text{H}_{40}\text{S}_2$, formed by union of two monomercapto-units, was isolated; its analytical figures and %SH content showed it to be a compound of the type (XV), the points of addition of the SH group, on the one hand, and of the

union through the S atom, on the other, allowing of three possible isomers (see p. 1539). This is confirmed by its infra-red absorption spectrum, which includes the characteristic absorptions of ·SH and CRR'·CHR'' groups.

Yields of the various derivatives with the olefins mentioned are indicated in Table I.

¹ These figures are too low as some thiol was lost on evaporation of the *isobutylene*.

² Not separated.

It was hoped that addition of hydrogen sulphide to rubber might be effected by shaking a rubber solution with the gas while irradiating it with ultra-violet light. However, even after 4 hours' irradiation of a solution of sol rubber (obtained by diffusion of acetone-extracted crepe rubber into light petroleum) only 1.1% of sulphur had entered the molecule. Although quartz apparatus was being used, this figure was doubled when acetone was added as a sensitizer, and small amounts of gelled material separated, which contained up to 10% of sulphur. The best value represents the saturation of 48% of the double bonds of rubber if the sulphur is assumed to be present as monosulphide.

It has been shown by Jones and Reid (*loc. cit.*) that peroxides catalyse the abnormal addition of thiols to olefins. Evidence for the catalytic effect of benzoyl peroxide on the addition of hydrogen sulphide to rubber in the present work was inconclusive. However, it was shown that

the addition reaction initiated by ultra-violet light was substantially inhibited by the natural antioxidants in rubber. Quam's report (*J. Amer. Chem. Soc.*, 1925, 47, 103) that rubber dissolves in liquid hydrogen sulphide was confirmed with milled acetone-extracted crepe, and when the resultant solution was irradiated with ultra-violet light as before, it gave rise to a product containing 2.1% of sulphur. The addition of acetone much reduced the solubility of the rubber, but it increased the sulphur intake to 3.2%.

Solid rubber reacted with hydrogen sulphide both in the presence and in the absence of sulphur, but the latter reaction was probably catalysed by ferrous sulphide on the walls of the steel autoclave. This view was confirmed by the addition of hydrogen sulphide to rubber in the presence of ferrous sulphide and ferric oxide. Although the results obtained with dihydromyrcene and geraniolene suggest that the main reaction with polyisoprenes is intramolecular, there is always some intermolecular addition, and it may well be that this is facilitated in the case of rubber by the intermolecular entanglements of the long chains. A characteristic of all the products which have been obtained from rubber by hydrogen sulphide addition, even when the combined sulphur value is as low as 1%, is their complete insolubility in all organic solvents once they have been separated from solution. It therefore seems evident that intermolecular sulphide and disulphide links of the type observed with cyclohexene and isobutylene are being formed. That there is a tendency for the average molecular weight to rise is shown by the fact that the observed molecular weight of a sample of milled rubber rose from 137,000 to 153,000 on treatment with hydrogen sulphide involving the incorporation of only 1% of sulphur. Rubber samples containing 2—3% of sulphur, which had been formed by reaction of solid rubber with hydrogen sulphide, exhibited many of the characteristics of a sulphur-vulcanised rubber, and although the porosity of the product precluded tensile strength tests, selected portions of the sheet were capable of over 700% elongation with good recovery. An attempt to obtain a smooth sheet for such tests by working at atmospheric pressure was unsuccessful, owing to the slowness of addition. The results obtained on both the *abnormal* and *normal* addition of hydrogen sulphide to rubber are summarised in Table II.

EXPERIMENTAL.

(Microanalyses were carried out by Dr. W. T. Chambers, Miss H. Rhodes, and Miss E. Farquhar.)

Hydrogen sulphide was prepared and purified by Quam's method (*loc. cit.*).

1-Methylcyclohexene and Hydrogen Sulphide.—1-Methylcyclohexene (10 g.), liquid hydrogen sulphide (7 g.), and acetone (1 g.) were sealed in a Pyrex tube, and irradiated with ultra-violet light for 60 minutes at 0°. The product was extracted with 10% aqueous sodium hydroxide (50 ml.) and with ether. From the alkaline extract was obtained 1-methylcyclohexane-2-thiol (1 g.), which was distilled at 56°/14 mm.; it was an evil-smelling, colourless liquid, which froze when cooled to 0° (Found: C, 63.8; H, 10.8; S, 23.8. $C_7H_{14}S$ requires C, 64.6; H, 10.8; S, 24.6%). The neutral portion, which was very small, distilled at 106°/0.1 mm., and appeared to consist of a mixture of di-2-methylcyclohexyl sulphide and disulphide (Found: C, 69.8; H, 10.7; S, 18.5. Calc. for $C_{14}H_{26}S$: C, 74.3; H, 11.5; S, 14.2. Calc. for $C_{14}H_{24}S_2$: C, 65.1; H, 10.1; S, 24.8%).

isobutylene and Hydrogen Sulphide (Sulphur Catalyst).—A mixture of isobutylene (56 g.), solid hydrogen sulphide (38 g.), and sulphur (0.5 g.) was introduced into a steel autoclave and heated for 14 hours at ca. 150°. After evaporation of unchanged hydrocarbon the product (12.2 g.) contained *tert.*-butanethiol (6.0 g.), di-*tert.*-butyl sulphide (2.6 g.), di-*tert.*-butyl disulphide (2.8 g.), and a non-volatile residue (0.5 g.). The thiol was redistilled to give a liquid, b. p. 63°, n_D^{20} 1.4212, and identified as its mercuric salt, m. p. 159–160° (Found: S, 16.8. Calc. for $C_8H_{18}S_2Hg$: S, 16.9%). After thorough extraction with 10% aqueous alkali, the monosulphide distilled at 51°/16 mm. and had n_D^{20} 1.4511 (Found: C, 65.5; H, 12.3; S, 21.9. Calc. for $C_8H_{18}S$: C, 65.7; H, 12.3; S, 21.9%). Fractionation of the disulphide gave a liquid, b. p. 79–80°/16 mm., n_D^{20} 1.4928 (Found: C, 53.9; H, 10.2; S, 35.9. Calc. for $C_8H_{16}S_2$: C, 53.9; H, 10.1; S, 35.9%).

In absence of sulphur, 14 hours' heating of a mixture of isobutylene (56 g.) and hydrogen sulphide (38 g.) gave a product containing *tert.*-butanethiol (1 g.), di-*tert.*-butyl sulphide (0.6 g.), and di-*tert.*-butyl disulphide (0.7 g.). In a further similar experiment, when air was completely excluded, after 18 hours at 130–150° the product consisted of thiol (1.5 g.), disulphide (0.4 g.), and a negligible quantity of sulphide.

tert.-Butanethiol (2 g.) was heated in a sealed tube in presence of air for 14 hours at 140–150°; it was mainly unchanged but contained di-*tert.*-butyl sulphide (0.2 g.) and hydrogen sulphide.

cyclohexene and Hydrogen Sulphide (Sulphur Catalyst).—A mixture of cyclohexene (100 g.), hydrogen sulphide (100 g.), and sulphur (0.5 g.) was heated for 24 hours at ca. 150°. Fractional distillation of the product gave cyclohexanethiol (3.5 g.), dicyclohexyl sulphide (13.5 g.), dicyclohexyl disulphide (2.5 g.), and a residue (1.5 g.). The thiol was purified by conversion with 10% aqueous alkali into its sodium salt, whose solution was acidified with hydrochloric acid under nitrogen; the redistilled thiol had b. p. 41°/12 mm., n_D^{20} 1.4988 (Found: C, 62.1; H, 10.2; S, 27.3. Calc. for $C_6H_{12}S$: C, 62.0; H, 10.3; S, 27.6%). To an alcoholic solution of the thiol was added hot aqueous mercuric cyanide. The precipitated oil was dissolved in hot alcohol and left to crystallise; on recrystallisation from methanol the mercaptide was obtained as colourless crystals, m. p. 71° (Found: S, 14.9; Hg, 46.4. $C_{12}H_{22}S_2Hg$ requires S, 14.9; Hg, 46.4%). The redistilled sulphide was a colourless liquid, b. p. 74°/0.2 mm., n_D^{20} 1.5162 (Found: C, 72.5; H, 11.1; S, 16.2. Calc. for $C_{12}H_{22}S$: C, 72.7; H, 11.1; S, 16.2%). and the disulphide a pale yellow liquid b. p. 110–112°/0.2 mm., n_D^{20} 1.5557 (Found: C, 63.0; H, 9.7; S, 27.4. Calc. for $C_{12}H_{20}S_2$: C, 62.7; H, 9.6; S, 27.8%). On standing with methyl iodide the monosulphide yielded a yellow oil which slowly solidified to the *methiodide* of dicyclohexyl sulphide; recrystallisation from ether containing a little alcohol gave colourless crystals, m. p. 110–111° (Found: I, 37.4. $C_{12}H_{22}SI$ requires I, 37.2%). This m. p. is the same as that obtained by Meyer and Hohenemser for the *methiodide* derived from the partly unsaturated sulphide (*Helv. Chim. Acta*, 1935, 18, 1061).

Dihydromyrcene.—Myrcene, prepared from bay oil (*Pimenta acris*) by the method of Power and Kleber (*Pharm. Rundschau*, 1895, 13, 60), was reduced with sodium and alcohol as described by Semmler and Mayer (*Ber.*, 1911, 44, 2010). The hydrocarbon, after being twice fractionally distilled over sodium, had b. p. 60°/16 mm., n_D^{20} 1.4542 (Found: C, 87.2; H, 12.9. Calc. for $C_{10}H_{18}$: C, 87.0; H, 13.0%).

Dihydromyrcene and Hydrogen Sulphide (Sulphur Catalyst).—A mixture of dihydromyrcene (69 g.), hydrogen sulphide (38 g.), and sulphur (0.5 g.) was heated in the autoclave for 20 hours at ca. 130°. On fractionation of the product the b. p. rose steadily from 50 to 90°/9 mm. and then from 68° to 80°/1 mm.; apart from unchanged dihydromyrcene, the distillate contained a mixture of isomeric monothiois, cyclic monosulphide (ca. 11 g.), and cyclic disulphide (2 g.), and a polymeric residue (1 g.) remained. The distillate fractions were extracted with 10% aqueous alkali in absence of air, and the extract after acidification was extracted with ether. Only a drop of liquid was thus obtained, but its odour was definitely mercaptan-like. Fractional distillation of the sulphide fractions gave a mixture of the $C_{10}H_{20}S$ isomers, (IV), (V), and (VI), b. p. 83°/9 mm., n_D^{20} 1.4858 (Found: C, 69.9; H, 11.4; S, 18.6. Calc. for $C_{10}H_{20}S$: C, 69.8; H, 11.6; S, 18.6%). With methyl iodide this product gave an oil, which on long standing yielded yellow crystals of the *methiodide*, m. p. 126–127° (decomp.) in insufficient quantity for complete purification (Found: I, 39.1. $C_{11}H_{22}I$ requires I, 40.3%). No pure disulphide was isolable but it was present to large extent in the higher fractions, such as one, b. p. 70°/1 mm., n_D^{20} 1.5202 (Found: C, 60.7; H, 10.0; S, 28.6. $C_{10}H_{20}S_2$ requires C, 58.8; H, 9.8; S, 31.3%).

A similar reaction between dihydromyrcene and hydrogen sulphide in the presence of sulphur, conducted at 160° for 22 hours, gave a product containing the $C_{10}H_{20}S$ isomers (15 g.), disulphide (3 g.), and polymeric compounds (1.5 g.).

The combined hydrocarbon fractions from the above experiments were again extracted with alkali, washed with water, dried (K_2CO_3), and distilled through a Fenske column. The recovered dihydromyrcene had b. p. 60°/16 mm., n_D^{20} 1.4511, and was shown by analytical and absorption-spectra measurements not appreciably to have cyclised or isomerised (Found: C, 87.2; H, 12.9; I.V., 362. Calc. for $C_{10}H_{18}$: C, 87.0; H, 13.0%; I.V., 368).

Geraniolene.—Citral was oxidised with silver oxide (Bernhauer and Forster, *J. pr. Chem.*, 1936, 147, 199), and the resulting geranic acid was decarboxylated at 260–270° (Tiemann and Semmler, *Ber.*,

1893, 26, 2724) to give geraniolene, b. p. $36^{\circ}/10$ mm., n_D^{20} 1.4408 (Found: C, 87.0; H, 12.9; I.V., 385. Calc. for $C_{10}H_{16}$: C, 87.1; H, 12.9%; I.V. 409). The low I.V. indicated the presence of some cyclised isomer.

Geraniolene and Hydrogen Sulphide (Sulphur Catalyst).—A mixture of geraniolene (70 g.), hydrogen sulphide (45 g.), and sulphur (0.5 g.) was heated in the autoclave for 24 hours at 150° . Distillation of the product gave a mixture of isomeric monothiol and cyclic monosulphide (12.5 g.), disulphide (1 g.), and a polymeric residue (1.5 g.). From the monosulphide fraction was obtained a pure mixture of the $C_{10}H_{16}S$ isomers (VII), (VIII), and (IX), b. p. $87^{\circ}/16$ mm., n_D^{20} 1.4812 (Found: C, 68.2; H, 11.4; S, 20.2%. Calc. for $C_{10}H_{16}S$: C, 68.4; H, 11.4; S, 20.2%). Reaction of this product with methyl iodide at 15° gave an oil which would not solidify. The fraction containing the highest percentage of disulphide had b. p. $75^{\circ}/1$ mm., n_D^{20} 1.5100 (Found: C, 59.0; H, 10.1; S, 29.3. $C_{10}H_{16}S_2$ requires C, 58.9; H, 9.5; S, 33.7%).

Geraniolene and Hydrogen Sulphide (Aluminium Sulphide Catalyst).—A mixture of geraniolene (42 g.), recovered from the foregoing experiment), hydrogen sulphide (38 g.), aluminium sulphide (6 g.), and quinol (2 g.) was heated in the autoclave in the absence of air for 26 hours at ca. 150° . The product in ethereal solution was thoroughly extracted with 10% aqueous sodium hydroxide, washed with water, and dried (Na_2SO_4). On exposure to air the alkaline extract immediately started oxidising, with the formation of a viscous red oil (evidently a polymeric disulphide). Fractional distillation of the ethereal extract gave the $C_{10}H_{16}S$ isomeric mixture (5.2 g.), with b. p. ranging from 69 – $71^{\circ}/11$ mm., n_D^{20} 1.4729 (Found: C, 68.5; H, 11.2; S, 19.9; $\cdot SH$, 8.7%), to 80 – $81^{\circ}/11$ mm., n_D^{20} 1.4778 (Found: C, 67.9; H, 11.4; S, 20.3; $\cdot SH$, 12.3. Calc. for $C_{10}H_{16}S$: C, 68.4; H, 11.4; S, 20.2; $\cdot SH$, 0%). Calc. for $C_{10}H_{16}\cdot SH$: $\cdot SH$, 20.9%). No disulphide was isolable, although one fraction (1.0 g.) contained a small proportion thereof (Found: S, 22.1. Calc. for $C_{10}H_{16}S$: S, 20.2. Calc. for $C_{10}H_{16}S_2$: S, 33.6%). An intermolecular sulphide fraction (0.5 g.), b. p. 117 – $122^{\circ}/0.5$ mm., n_D^{20} 1.4988, was isolated, and it appeared to be mainly the compound $C_{10}H_{16}S\cdot C_{10}H_{16}\cdot SH$ (see p. 1539) containing some $C_{10}H_{16}\cdot S\cdot C_{10}H_{16}$ (Found: C, 70.0; H, 11.1; S, 18.7. Calc. for $C_{10}H_{16}S_2$: C, 68.4; H, 11.4; S, 20.2%. Calc. for $C_{10}H_{16}S_2$: C, 76.6; H, 12.0; S, 11.3%).

Separation of the $C_{10}H_{16}S$ isomers. An approximately 0.2N-solution of cupric butyl phthalate (Turk and Reid, *loc. cit.*) was prepared by dissolving the reagent (5.1 g.) in 100 ml. of *n*-propyl alcohol containing acetic acid (5 ml.). This reagent was introduced into a solution of the $C_{10}H_{16}S$ mixture (3.3 g.) in *n*-propyl alcohol (50 ml.) until the green colour just persisted. After dilution with water to 800 ml. the product was extracted with chloroform, washed with water, dried, and fractionally distilled. After refractionation, 2:2:6-tetramethyltetrahydrothiopyran (IX) (1 g.) was obtained as a colourless liquid, b. p. 64 – $66^{\circ}/11$ mm., n_D^{20} 1.4732 (Found: C, 68.4; H, 11.3; S, 19.9. Calc. for $C_{10}H_{16}S$: C, 68.4; H, 11.4; S, 20.2%).

Reaction of (IX) with methyl iodide at 0° gave only an oil, but when the sulphide was heated with excess of methyl iodide at 100° for 12 hours, yellow crystals separated, which after being washed with methanol and recrystallised from ethanol decomposed at ca. 200° and proved to be trimethylsulphonium iodide (Found: S, 15.7; I, 61.9. Calc. for C_3H_9SI : S, 15.7; I, 62.2%).

2:6-Dimethylocta-2:6-diene.—Geraniol was purified by conversion into its calcium chloride compound, and then reduced by sodium in liquid ammonia (Chablay; Dupont, Dulou, and Desreux, *loc. cit.*). After fractional distillation over sodium, the pure hydrocarbon had b. p. $56^{\circ}/14$ mm., n_D^{20} 1.4517 (Found: C, 87.0; H, 13.2; I.V., 370. Calc. for $C_{10}H_{18}$: C, 87.0; H, 13.0%; I.V., 368).

2:6-Dimethylocta-2:6-diene and Hydrogen Sulphide (Normal Addition).—A mixture of the olefin (69 g.), hydrogen sulphide (38 g.), and sulphur (0.5 g.) was heated in absence of oxygen under pressure for 22 hours at 140 – 150° . After extraction with aqueous alkali, fractional distillation of the product gave a mixture of $C_{10}H_{16}S$ isomers (5 g.) and a higher-boiling fraction which in this instance was not separated. Refractionation of the former yielded the $C_{10}H_{16}S$ isomers, b. p. 92 – $94^{\circ}/18$ mm., n_D^{20} 1.4842 (Found: C, 69.8; H, 11.5; S, 18.3. Calc. for $C_{10}H_{16}S$: C, 69.8; H, 11.6; S, 18.6%); this fraction contained about 11% of the monothiol (Found: $\cdot SH$, 2.1. Calc. for $C_{10}H_{16}\cdot SH$: $\cdot SH$, 19.2%). The unreacted olefin was recovered and shown to be uncyclised 2:6-dimethylocta-2:6-diene, b. p. $54^{\circ}/13$ mm., n_D^{20} 1.4501 (Found: C, 87.0; H, 13.2; I.V., 370. Calc. for $C_{10}H_{18}$: C, 87.0; H, 13.0%; I.V., 368).

In a further similar experiment 2:6-dimethylocta-2:6-diene (92 g.) was treated with hydrogen sulphide (58 g.) in the presence of aluminium sulphide (10 g.) for 23 hours at 150 – 165° . After extraction with 10% aqueous sodium hydroxide solution, the product was distilled as before to give the $C_{10}H_{16}S$ fraction (11 g.), b. p. ca. 76 – $89^{\circ}/9$ mm.), disulphide (0.5 g., not isolable), and a residue of intermolecular sulphides (0.5 g.). On refractionation of the $C_{10}H_{16}S$ fraction, a product was obtained, b. p. 87 – 88° , n_D^{20} 1.4798 (Found: C, 69.6; H, 11.6; S, 18.6. Calc. for $C_{10}H_{16}S$: C, 69.8; H, 11.6; S, 18.6%), which contained ca. 27% of the monothiol 2(or 6)-mercapto-2:6-dimethyloct-6(or 2)-ene (Found: $\cdot SH$, 5.1. Calc. for $C_{10}H_{16}\cdot SH$: $\cdot SH$, 19.2%). Treatment of this product with copper butyl phthalate, in a manner analogous to that used for separation of the $C_{10}H_{16}S$ isomers, led to the isolation of 2:2:6-trimethyl-6-ethyl-tetrahydrothiopyran, b. p. $84^{\circ}/10$ mm., n_D^{20} 1.4792 (Found: C, 69.4; H, 11.5; S, 18.3. Calc. for $C_{10}H_{16}S$: C, 69.8; H, 11.6; S, 18.6%). Reaction with methyl iodide at 0 – 15° gave an oil which crystallised only extremely slowly, and reaction at 100° gave trimethylsulphonium iodide (Found: S, 15.7; I, 61.9. Calc. for C_3H_9SI : S, 15.7; I, 62.2%). By acidification of the alkali extract and subsequent extraction with ether was obtained 2:6-dimercapto-2:6-dimethyloctane (0.5 g.), b. p. $110^{\circ}/9$ mm., n_D^{20} 1.4971 (Found: C, 58.2; H, 10.6; S, 31.0; $\cdot SH$, 32.0. $C_{10}H_{16}S_2$ requires C, 58.3; H, 10.7; S, 31.0; $\cdot SH$, 32.0%).

In a third experiment a mixture of 2:6-dimethylocta-2:6-diene (77 g.), hydrogen sulphide (48 g.), aluminium sulphide (8 g.), and quinol (2 g.) was heated for 24 hours at ca. 150° . From the $C_{10}H_{16}S$ fraction (7.5 g.) was obtained a mixture of isomers, b. p. 86 – $8^{\circ}/10$ mm., n_D^{20} 1.4782 (Found: C, 69.7; H, 11.5; S, 18.7. Calc. for $C_{10}H_{16}S$: C, 69.8; H, 11.6; S, 18.6%), which contained 42% of the monothiol (Found: $\cdot SH$, 8.0. Calc. for $C_{10}H_{16}\cdot SH$: $\cdot SH$, 19.2%). Removal of the latter by the copper butyl phthalate method left somewhat impure 2:2:6-trimethyl-6-ethyl-tetrahydrothiopyran, b. p. 80 – $83^{\circ}/11$ mm., n_D^{20} 1.4806 (Found: C, 70.7; H, 11.6; S, 17.5. Calc. for $C_{10}H_{16}S$: C, 69.8; H, 11.6; S, 18.6%).

2:6-Dimethylocta-2:6-diene and Hydrogen Sulphide (Abnormal Addition).—Two Pyrex tubes, each containing the olefin (18.3 g.), hydrogen sulphide (5.1 g.), and acetone (1.2 g.), were sealed under vacuum and irradiated with U.V. light at 15° for 4 hours. After extraction with 10% aqueous alkali, the product was fractionally distilled to give a $C_{10}H_{18}S$ isomeric mixture (9 g.) and intermolecular sulphides (2 g.). From the former was obtained a fraction, b. p. 92–92.5°/11 mm., n_D^{20} 1.4767 (Found: C, 69.8; H, 11.6; S, 18.6. Calc. for $C_{10}H_{18}S$ requires C, 69.8; H, 11.6; S, 18.6%), which contained 56% of the monothiol, 3(or 7)-mercapto-2:6-dimethyloct-6(or 3)-ene (Found: $\cdot SH$, 10.8. $C_{10}H_{18}\cdot SH$ requires $\cdot SH$, 19.2%). Removal of the thiol by the copper butyl phthalate method left 2:3-dimethyl-6-isopropyl-tetrahydrothiopyran, b. p. 46°/1 mm., n_D^{20} 1.4831 (Found: C, 69.7; H, 11.5; S, 18.2. $C_{10}H_{18}S$ requires C, 69.8; H, 11.6; S, 18.6%). Acidification of the alkaline extract liberated 3:7-dimercapto-2:6-dimethyloctane, b. p. 132°/11 mm., n_D^{20} 1.5025 (Found: C, 58.3; H, 11.0; S, 30.8. $C_{10}H_{18}S_2$ requires C, 58.3; H, 10.7; S, 31.0%). Fractionation of the intermolecular sulphide fraction led to the separation of 5(or 2)-mercapto-1:2:6-trimethylheptyl 4-methyl-1-isopropylhex-4-enyl sulphide or the 1:5-dimethyl-1-ethylhex-4-enyl sulphide (as XV), b. p. 147°/0.1 mm., n_D^{20} 1.4990 (Found: C, 69.4; H, 11.6; S, 18.8; $\cdot SH$, 10.0. $C_{10}H_{18}S$ requires C, 69.8; H, 11.6; S, 18.6; $\cdot SH$, 9.6%).

Nitrous Acid Test for Thiols.—Dilute sulphuric acid was slowly added to an alcoholic solution of the thiol containing solid sodium nitrite, through which nitrogen was bubbling (Rheinboldt, *loc. cit.*). All the products of normal addition of hydrogen sulphide to dihydromyrcene and 2:6-dimethylocta-2:6-diene gave green oils which appeared red in bulk when viewed by transmitted light; this was indicative of the tertiary grouping $CRR'R''SH$. The U.V.-light-catalysed reaction product gave a bright red oil indicating the secondary grouping $CHRR'SH$ (the formation of a primary thiol not being feasible in this reaction), and the geraniolene products a reddish oil, which pointed to the presence of at least some secondary thiol.

Rubber and Hydrogen Sulphide (Abnormal Addition).—A 1% benzene solution of sol rubber was shaken with hydrogen sulphide in absence of air, and irradiated in a quartz flask with ultra-violet light for 4 hours. The product after separation by precipitation with alcohol and drying in a high vacuum contained 1.1% of sulphur. The experiment was repeated using as solvent benzene containing 5% of acetone as photosensitiser. From two runs the products contained 2.25 and 2.65% of sulphur severally; a very small quantity of rubber came out of solution as a gel, and in the latter case this contained 10.1% of sulphur. When crepe containing its natural antioxidants was used, the sulphur value obtained was 0.8%. Seven hours' irradiation of a 9% solution of milled acetone-extracted crepe in benzene containing 5% of acetone gave small quantities of gels containing 4.5–2.2% of sulphur, and a main product with 1% (M , 153,000). The same conditions, 1% solutions being used without irradiation, led to incorporation of only 0.15% of sulphur. A further solution was saturated with hydrogen sulphide at 0° and then heated with benzoyl peroxide for 1 hour at 75°; this increased the sulphur intake to 0.30%.

Milled acetone-extracted crepe (0.5 g.) and liquid hydrogen sulphide (30 ml.) were sealed in a Pyrex tube. After 3 days with occasional gentle shaking the rubber passed into solution, and was then irradiated for 25 minutes at 15°; the product contained 2.07% of sulphur. On repetition of the experiment with milled crepe (0.7 g.), hydrogen sulphide (24 ml.), and acetone (1.2 ml.), the rubber did not go wholly into solution. The analyses of the two portions after 25 minutes irradiation were: Found, for insoluble fraction, C, 85.6; H, 11.6; S, 1.3; ash, 0.17; O (diff.), 1.3%. Found, for soluble fraction, C, 85.0; H, 11.65; S, 3.2; ash, 0.09; O (diff.), 0.06%. It is evident that liquid hydrogen sulphide preferentially dissolved the pure hydrocarbon, as the starting material contained 1.0% of oxygen.

Rubber and Hydrogen Sulphide (Normal Addition).—Similar 1-mm. sheets (10 g.) of crepe rubber, milled alone and with $\frac{1}{4}$ % of sulphur, were heated with hydrogen sulphide (24 g.) in the autoclave in absence of air for 2 hours at 140°. The products, although full of small hydrogen sulphide bubbles, were elastic like sulphur-vulcanised rubber (Found, for uncatalysed product: S, 1.9; 2.2. For catalysed product: S, 2.7; 2.8%). After a similar reaction at 140–160° the products were acetone-extracted to remove free sulphur (Found, for uncatalysed product: S, 2.75. For catalysed product: S, 3.25%); at this temperature acetone-extracted crepe rubber reacted to give a product (Found: S, 3.15%) after further acetone-extraction. Reaction of milled crepe (10 g.) with hydrogen sulphide (24 g.) for 2 hours at 260° yielded a product in which some chain fission had obviously taken place (Found: S, 8.5%). Sheets of milled crepe with and without $\frac{1}{4}$ % of sulphur were heated at 140° for 48 hours in hydrogen sulphide at atmospheric pressure (Found, for uncatalysed product: S, 0.5; for catalysed product, S, 0.8%); a control sample heated in nitrogen was unchanged.

An 8% solution (250 ml.) of milled acetone-extracted crepe rubber in cyclohexane, liquid hydrogen sulphide (60 g.), ferrous sulphide (4 g.), and ferric oxide (2 g.) were sealed in the autoclave in absence of air and heated for 20 hours at 85–103°. Some rubber (3–4 g.) came out of solution as a gel (Found: S, 4.8%). The main solution was centrifuged to remove catalyst, and the rubber precipitated by alcohol (Found: S, 1.1%).

This paper forms part of a programme of fundamental research undertaken by the Board of the British Rubber Producers' Research Association. The author wishes to express his thanks to Dr. E. H. Farmer for his advice and criticism, to Dr. G. B. M. Sutherland and Mr. N. Sheppard for examination of the infra-red absorption spectra and for valuable discussions on their inference, and to Dr. G. Gee for the molecular-weight determinations.

300. *The Application of Infra-red Analysis to the Study of the Reaction of Certain Olefins with Hydrogen Sulphide.*

By N. SHEPPARD and G. B. B. M. SUTHERLAND.

The method of infra-red analysis has been used to investigate the reaction of geraniolene and dihydromyrcene with hydrogen sulphide in the presence of catalysts that usually promote "normal" addition to the double bond according to the Markovnikov rule. It has been possible to show conclusively that under these conditions both the hydrocarbons give mono-addition products which consist partly of cyclic sulphides, geraniolene giving rise to 2 : 2 : 6 : 6-tetramethyltetrahydrothiopyran, and dihydromyrcene to 2 : 2 : 6-trimethyl-6-ethyltetrahydrothiopyran. Such products could only have been formed by "normal" addition reactions. The products of the reaction of hydrogen sulphide with dihydromyrcene under conditions favouring "abnormal" addition gave very different spectra.

In order to apply the infra-red method it was necessary first to establish rules for the spectroscopic identification of certain hydrocarbon groups. These rules are briefly discussed.

IN the preceding paper Naylor has described an investigation of the reaction of hydrogen sulphide with the hydrocarbons geraniolene and dihydromyrcene. Many of the conclusions relating to the structures of the reaction products came from an investigation of their infra-red spectra. The purpose of this paper is to present in detail the evidence for these conclusions.

Infra-red analysis can be used in two ways to establish the structure of a reaction product. In the first place, any chemical bond or group that has characteristic infra-red absorption bands can be detected, and while in most cases this does not establish the structure it may enable one to eliminate some of the possible formulations and give strong presumptive evidence for a particular one. The second and more conclusive method is to compare the spectrum of the reaction product with that of a specially synthesised specimen of the compound postulated as the reaction product. Both methods have been used in the present investigation, the first two sections of which are concerned with the material required for the first method, while the third contains the combined application of both methods to the problem in hand.

Chemical Groupings and their Characteristic Absorption Bands.—The various characteristic group frequencies that we shall use in the examination of the reaction products are given in Table I, where R represents an alkyl group. Most of these correlations are well established

TABLE I.

Chemical grouping.	Type of vibration.	Frequency in cm^{-1} .
SH	SH valence	2500—2650
CH_2 and CH_3	CH deformation	1430—1470
CH_3	CH deformation	1370—1375
$\text{C} \begin{smallmatrix} \diagup \text{CH}_3 \\ \diagdown \text{CH}_3 \end{smallmatrix}$	CH deformation	ca. 1360 and 1380 *
$\text{RR}'\text{C}:\text{CH}_2$	$\text{C}=\text{C}$ valence	1645—1655 *
$\text{RR}'\text{C}:\text{CH}$	CH deformation	885—895
$\text{RR}'\text{C}:\text{CHR}''$	$\text{C}=\text{C}$ valence	1670—1680 *
$\text{RR}'\text{C}:\text{CHR}''$	CH deformation	800—840

(see, e.g., Herzberg, "Infra-red and Raman Spectra of Polyatomic Molecules," Van Nostrand Co. Inc., 1946; Barnes, Gore, Liddel, and Williams, "Infra-red Spectroscopy," Reinhold, 1944; Thompson and Torkington, *Trans. Faraday Soc.*, 1945, **41**, 246), but those marked with an asterisk, which are more precise characterisations of older correlations, have recently been established in this laboratory and full details will be published elsewhere.

Both the $\text{C}=\text{C}$ valence and the $\text{C}-\text{H}$ deformation absorptions of the disubstituted ethylenes have considerably higher extinction coefficients than the corresponding absorptions of the trisubstituted compounds. This is important if such absorptions are used to estimate the relative amounts of the two types of grouping in a mixture of both.

The Spectra of the Olefins.—The two hydrocarbons originally used for the reaction with hydrogen sulphide were geraniolene and dihydromyrcene. Their spectra are shown in Fig. 1, and in this and the subsequent figures absorption bands mentioned in the text are accented by a line down the middle in the appropriate spectra.

Geraniolene is considered to be mainly 2 : 6-dimethylhepta-1 : 5-diene,

although its method of preparation (Bernhauer high-temperature decarboxylation; see Naylor, *loc. cit.*) does not exclude the possibility of considerable amounts of other isomers. Its infra-red spectrum has absorption bands at 1654 and 891 cm^{-1} , and at 1680 and 821 cm^{-1} which

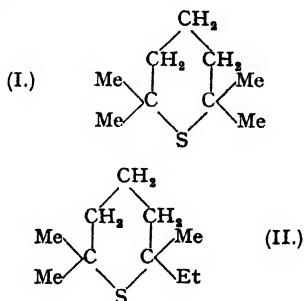

can be ascribed to $C=C$ valence and $C-H$ deformation vibrations respectively of $RR'C:CH_2$ and $RR'C:CHR''$ groups, in agreement with the above formula (see Table I).

Dihydromyrcene is generally assumed to consist largely of 2:6-dimethylocta-2:6-diene, $CH_3 \cdot CMe:CH \cdot CH_2 \cdot CH_2 \cdot CMe:CH \cdot CH_3$, but its method of preparation (Naylor, *loc. cit.*) suggests that the isomers 2:6-dimethylocta-1:6-diene, $CH_3 \cdot CMe:CH_2 \cdot CH_2 \cdot CH_2 \cdot CMe:CH \cdot CH_3$, and 6-methyl-2-ethylhepta-1:5-diene,

$CH_3 \cdot CMe:CH \cdot CH_2 \cdot CH_2 \cdot CEt:CH_2$, may also be present. Comparison of the spectrum of this material with that of pure 2:6-dimethylocta-2:6-diene, prepared by an independent method, shows that in addition to the usual bands attributable to the $RR'C:CHR''$ groups (at 1678 and 820 cm^{-1}) there are also bands (at 1650 and 889 cm^{-1}) attributable to the $RR'C:CH_2$ groups of these alternative isomers. For this reason the dihydromyrcene used in the earlier experiments with hydrogen sulphide and sulphur catalyst was subsequently replaced by the pure 2:6-dimethylocta-2:6-diene.

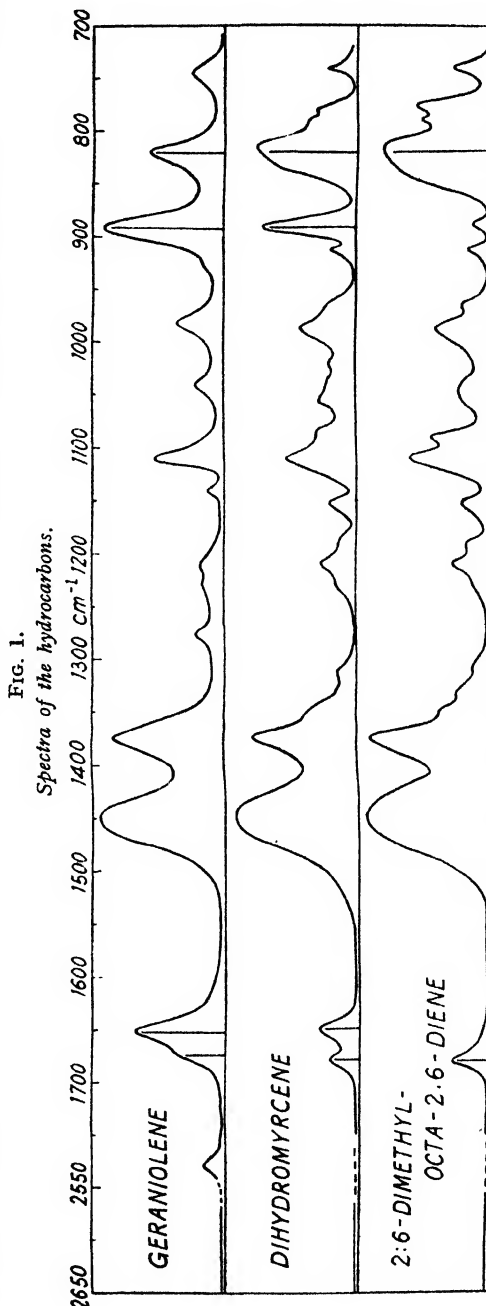

Infra-red Analysis of the Reaction Products.—

(1) *General.* The chemical aspects of the reactions of geraniolene and dihydromyrcene with hydrogen sulphide have been fully discussed by Naylor (*loc. cit.*). The spectroscopic problem was to investigate certain portions of the products obtained with catalysts that promote "normal" addition according to the Markovnikov rule. In particular we required to establish the presence or absence of 2:2:6:6-tetramethyltetrahydrothiopyran (I) and 2:2:6-trimethyl-6-ethyltetrahydrothiopyran (II) as reaction products of the respective hydrocarbons.

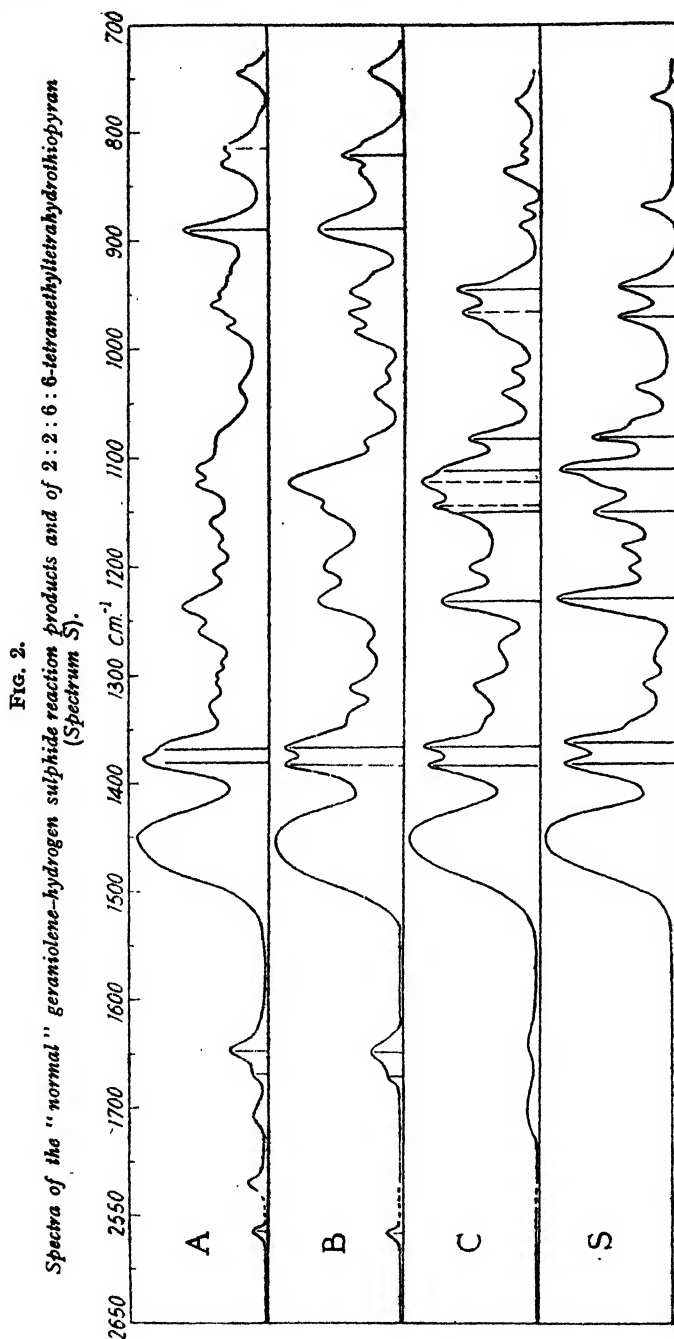

We also investigated some products from similar reactions in which the conditions were such that products of "abnormal" addition were to be expected.

The spectra of the reaction products of geraniolene and hydrogen sulphide obtained under conditions of normal addition are given in Fig. 2, the steps in the gradual purification and identification being indicated by the following key: (A) Spectrum of the reaction product, sulphur being used as catalyst. (B) Spectrum of the reaction product, aluminium sulphide being used as catalyst (to avoid the possibility of the catalyst reacting with the hydrocarbon). (C) Spectrum of B after removal

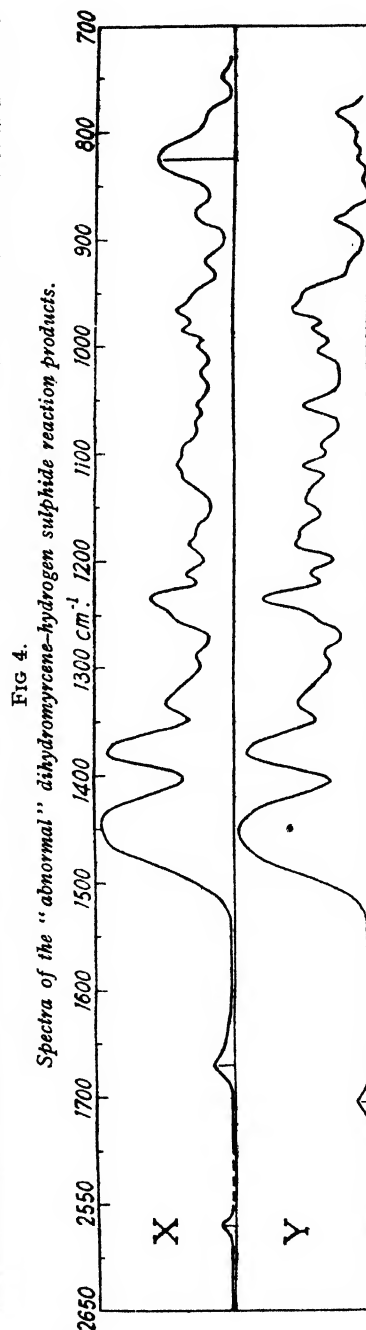

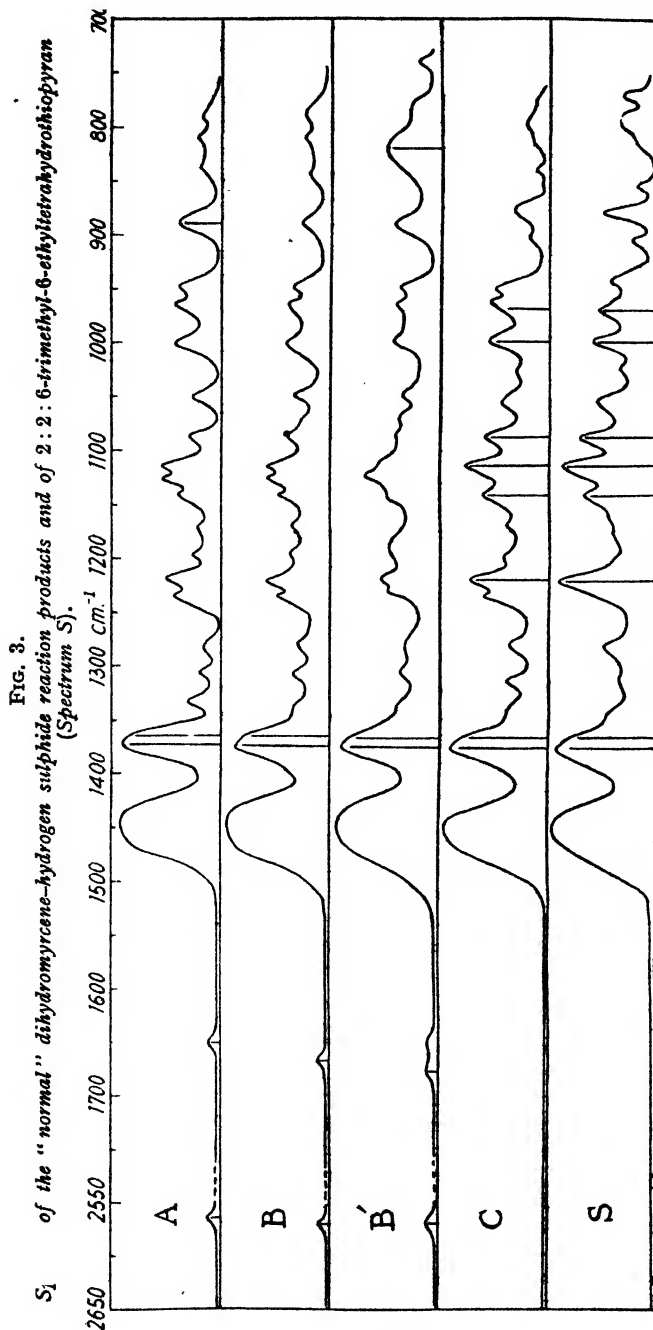

of thiols by cupric butyl phthalate. (S) Spectrum of synthetic 2:2:6:6-tetramethyltetrahydrothiopyran.

The corresponding spectra for the dihydromyrcene reaction are given in Fig. 3, but it should be noted that only (A) refers to the reaction with dihydromyrcene; the remaining spectra are all of products obtained by using the synthetic specimen of the single isomer 2:6-dimethylocta-2:6-diene of which the spectrum is given in Fig. 1. It should also be noted that (B') of Fig. 3 is the spectrum of a reaction product obtained under the same conditions as (B) but

with some quinol present to remove any peroxides. As in the case of the geraniolene products, (C) and (S) denote respectively the thiol-free product and the independently synthesised cyclic sulphide.

In Fig. 4 are represented the spectra of the products obtained when 2:6-dimethylocta-2:6-diene and hydrogen sulphide are irradiated with ultra-violet light—conditions that should promote abnormal addition: (X) is the original unpurified product, and (Y) the thiol-free material.

(2) *The products of the geraniolene-hydrogen sulphide reaction under "normal" conditions* (see Fig. 2). The expected product—2:2:6:6-tetramethyltetrahydrothiopyran—has four methyl groups that occur in pairs, and this should give rise to the splitting of the 1370 cm^{-1} band. Such a splitting (1381 and 1362 cm^{-1}) is found in the spectrum of the synthetic material (S), and confirms its authenticity. Other bands in the spectrum of (S) which can be used for the identification of this sulphide in the reaction product occur at 1229, 1149, 1111, 1079, 971, and 942 cm^{-1} .

Product A (sulphur as catalyst) has a poorly defined spectrum which shows little splitting of the 1370 cm^{-1} band, and in addition has absorptions at 1648 and 889 cm^{-1} characteristic of $\text{RR}'\text{C}:\text{CH}_2$ groupings, 1670 and 815 cm^{-1} characteristic of $\text{RR}'\text{C}:\text{CHR}''$ groupings, and 2570 cm^{-1} caused by SH groups. In other words, it is obvious that further purification was necessary, and that at least some of the impurities were residual amounts of monothiol.

The aluminium sulphide-catalysed product (B) has a cleaner spectrum—due probably to the absence of any sulphur-geraniolene products—but still retains the other groupings corresponding to the monothiol. However, after removal of these by cupric butyl phthalate (product C) a fairly clean spectrum is obtained with, as required, a pronounced splitting of the 1370 cm^{-1} band (1381 and 1363 cm^{-1}). In addition, the strong bands which occur at 1231, 1150, 1111, 1082, and 945 cm^{-1} show that there is a considerable amount of the expected sulphide present. Several well-pronounced bands remain, however, which are not due to the expected product, and one of these obscures the 971 cm^{-1} position. The three strongest bands which cannot be attributed to this sulphide have their centres at 1144, 1122, and 965 cm^{-1} , all of which are very close to strong absorptions of the synthesised cyclic sulphide.

(3) *The products of the dihydromyrcene-hydrogen sulphide reaction under "normal" conditions* (see Fig. 3). The spectrum of the specially synthesised 2:2:6-trimethyl-6-ethyltetrahydrothiopyran (S) has absorptions at 1220, 1142, 1116, 1087, 1002, 970 cm^{-1} which can be used for identification purposes. In this case the splitting of the 1370 cm^{-1} band is only just detectable, as is to be expected, since there are equal numbers of "paired" and "lone" methyl groups present. It is interesting to note a strong general resemblance between this spectrum and that of 2:2:6:6-tetramethyltetrahydrothiopyran, and this correspondence confirms the closely related structures of these two substances.

Product A (sulphur as catalyst) gives the spectrum shown at the top of Fig. 3. A small proportion of SH groups is indicated by the usual band at 2570 cm^{-1} , and also some unsaturation of the disubstituted type $\text{RR}'\text{C}:\text{CH}_2$ by the bands at 1650 and 889 cm^{-1} . The fact that some of the residual unsaturation is of the disubstituted type in this case is surprising in view of the fact that the initial hydrocarbon should have few such groupings. However, product B (with pure 2,6-dimethylocta-2:6-diene and aluminium sulphide as catalyst) does not show any considerable absorptions in these positions, and the probability that this disubstituted unsaturation is due to some sulphur-dihydromyrcene reaction products is substantiated by the presence of bands at 1650 and 890 cm^{-1} in the spectra of such products (unpublished work). Very weak bands at 2570 cm^{-1} and *ca.* 1660–1670 cm^{-1} suggest that there is some residue including thiol. Product B' (obtained as B but with quinol present) has a considerable number of SH and unsaturated groupings—the latter being predominantly of the trisubstituted type (1680 and 820 cm^{-1}). Otherwise its spectrum is very similar to that of B, indicating that the removal of any peroxides that might have been present during the reaction had little effect on the product. This is additional evidence that it is not formed by "abnormal" addition.

Finally, the removal of thiol from (B) by cupric butyl phthalate (product C) caused the disappearance of SH and unsaturation absorptions. The resultant material gives a reasonably clean spectrum. Comparison of this spectrum (C) with that of the synthesised material (S) which was taken with the same path-length of liquid, shows that all the characteristic bands of 2:2:6-trimethyl-6-ethyltetrahydrothiopyran are present in strength comparable with those of the pure material. One or two weak additional bands are present in (C) which presumably correspond to a small amount of impurity, but the product is very nearly all pure sulphide of the expected type.

(4) *The products of the dihydromyrcene-hydrogen sulphide reaction under "abnormal" conditions* (see Fig. 4). The product (X) was formed by the ultra-violet-catalysed reaction between pure 2:6-dimethylocta-2:6-diene and hydrogen sulphide and would be expected to be "abnormal" in type. It has a very different spectrum from those products discussed in the preceding section although it does have bands at 2580 cm^{-1} (SH groups) and at 1670 and 825 cm^{-1} characteristic of trisubstituted double bonds. This means that there is a considerable proportion of monothiol present. Removal of this by the usual method gave product

(Y), which has a spectrum similar to (X) except that the above three bands have disappeared. There remains a weak band near 1700 cm^{-1} which is probably due to some impurity introduced during the removal of thiol, as such a frequency is characteristic of C=O rather than $\text{C}\equiv\text{C}$ groups. The spectrum of this sample is completely different from that of the final "normal" product of Section (3).

DISCUSSION.

We have shown that the spectra of the reaction products under conditions favouring "normal" addition are extremely similar to those of 2:2:6:6-tetramethyl- and 2:2:6-trimethyl-6-ethyl-tetrahydrothiopyran, but there are certain discrepancies which must be considered before this strong resemblance can be accepted as conclusive proof of the identities of the reaction products. When spectra differ in this way it may be either because impurities are present, or because the compounds of which the spectra are being compared are really different, but of closely related structure. These two cases, which we shall call (1) and (2), can usually be distinguished. In the former, the main bands of the pure compound should be stronger than the corresponding bands in the unknown for the same cell thickness, unless, of course, a band due to the impurity overlaps one of these "key" bands. From Figs. 2 and 3 it will be seen that this is indeed the case for our comparisons. Again, in case (1) all bands, except the very weakest, detectable in the spectrum of the pure compound should be present in the unknown, whereas in case (2) the number of weak bands may be greater for the pure compound than the unknown. It will be seen that on this criterion also our identification is justified, for although there is one weak band in 2:2:6:6-tetramethyltetrahydrothiopyran (near 1180 cm^{-1}) which does not appear in the (C) spectrum (Fig. 2), this sole exception may well be due to a trace of impurity in the synthetic compound.

In the case of the comparison of the geraniolene product with the synthetic 2:2:6:6-tetramethyltetrahydrothiopyran, it is obvious that the amount of "impurity" is considerable and it is thought that this arises from the presence of other isomers than 2:6-dimethylhepta-1:5-diene in the original hydrocarbon. The dihydromyrcene product has relatively little impurity, in agreement with the fact that pure 2:6-dimethylocta-2:6-diene was used for the reaction.

We wish to draw attention in this connection to the power of the infra-red method in detecting by-products in a reaction. The difficulty of sufficiently purifying the product to enable us to use infra-red analysis is a sufficient indication of this, and of the precision of the identification once that purification has been achieved.

EXPERIMENTAL.

The infra-red spectra were taken with the Hilger Double-Beam Spectrometer described by Sutherland and Thompson (*Trans. Faraday Soc.*, 1945, **41**, 174). They were recorded under double-beam conditions so that the absorption of radiation by water vapour in the atmosphere did not interfere with the spectra.

1546 Reaction of Sulphur and Sulphur Compounds, etc. Part III.

A rock-salt prism was used throughout for this work, and the effective slit-widths (in cm^{-1}) were 40 at 2000 cm^{-1} , 12 at 1600 cm^{-1} , 8 at 1000 cm^{-1} , and 5 at 700 cm^{-1} . The positions of the bands are accurate to 2 cm^{-1} up to 1300 cm^{-1} , 4 cm^{-1} from 1300 to 1900 cm^{-1} , and 20 cm^{-1} at any higher frequencies in this work.

The experimental details of the olefin-hydrogen sulphide reactions have been given by Naylor (*loc. cit.*) and it will suffice here to give the physical properties and analytical figures for the samples investigated. These figures were obtained by Naylor at Welwyn, and the samples were then sealed in nitrogen and transmitted to Cambridge. The spectra were taken in a rock-salt cell of 0.06 mm. thickness, immediately after the samples had been unsealed.

Our thanks are due to Drs. E. H. Farmer and R. F. Naylor, of the British Rubber Producers' Research Association, for bringing this problem to our notice, and for providing us with all the specimens investigated. We are also grateful to them for much helpful discussion during the course of the work.

One of us (N. S.) is indebted to St. Catharine's College, and the Dunlop Rubber Co. Ltd., for financial help during this investigation. The spectrometer used was provided by a joint grant from the Royal Society and Imperial Chemical Industries Ltd.

LABORATORY OF COLLOID SCIENCE, CAMBRIDGE.

301. The Reaction of Sulphur and Sulphur Compounds with Olefinic Substances. Part III. The Reaction of Sulphur with Squalene.

By GEORGE F. BLOOMFIELD.

Sulphur reacts with squalene in a manner very similar to that observed with dihydromyrcene, and an intramolecularly-linked unimolecular sulphide as well as an intermolecularly-linked polysulphide is obtained.

RATHER prolonged reaction times are necessary to obtain an appreciable degree of sulphuration of squalene, $\text{H}[\text{CH}_2\cdot\text{CMe}\cdot\text{CH}\cdot\text{CH}_2]_3[\text{CH}_2\cdot\text{CH}\cdot\text{CMe}\cdot\text{CH}_2]_3\cdot\text{H}$, below 140° in the absence of auxiliary activating substances, and, as might be expected, the course of the reaction shows a marked resemblance to the sulphuration of dihydromyrcene. The crude reaction product consists of unreacted squalene of undiminished olefinic unsaturation, together with a unimolecular sulphurated product and a bimolecular polysulphide. Of the two sulphurated components, the unimolecular product, which cannot be completely freed from unreacted squalene, is present in the major proportion, although the sulphur which enters into reaction is distributed fairly equally among the two components. The unimolecular product, $\text{C}_{30}\text{H}_{50}\text{S}$, in which one sulphur atom has become incorporated in the squalene molecule with the loss of one double bond, is substantially free from sulphydryl sulphur, and contains carbon and hydrogen in the same ratio as in the original hydrocarbon. The bimolecular product is a polysulphide of squalene, $\text{C}_{60}\text{H}_{100}\text{S}_6$, of considerable stability towards sodium sulphite, and the ratio of hydrogen to carbon is again that of the parent hydrocarbon; the incorporation of sulphur is accompanied by loss of olefinic unsaturation. The unsaturation of the bimolecular product undergoes a further reduction on heating at temperatures exceeding 140° .

In view of the known sensitivity of the reaction of sulphur with olefins towards quite small proportions of certain activating substances, it is of considerable interest that the addition of mercaptobenzthiazole and a zinc soap to the sulphur-squalene system results only in increased yields in both uni- and bi-molecular products without greatly affecting their relative proportions, provided that the time and temperature conditions of the reaction remain unaltered.

EXPERIMENTAL.

Microanalyses were carried out by Dr. W. T. Chambers and Miss H. Rhodes. Olefinic unsaturation was determined by bromine addition (Bloomfield, *J. Soc. Chem. Ind.*, 1945, **64**, 274), and molecular weights were determined by depression of f. p. of benzene.

Squalene (14 g.) was heated with sulphur (1.4 g.) in an atmosphere of nitrogen for 3 hrs. at 140° . The product was freed from unreacted sulphur first by cooling and filtering, and finally by passage through a falling-film molecular still (Farmer and Sutton, *ibid.*, 1946, **65**, 164) at 100° . Subsequent molecular distillation of the product at 140° gave a pale yellow distillate (13 g.) having n_D^{20} 1.5031 (Found: C, 86.1; H, 12.0; S, 2.1; $\cdot\text{SH}$, 0.09; I.V., 338; M , 412. Calc. for mixture of 71% $\text{C}_{30}\text{H}_{50}\text{S}$ and 29% $\text{C}_{60}\text{H}_{100}\text{S}_6$: C, 85.7; H, 12.2; S, 2.1; I.V. 348; M , 420) which showed selective U.V. absorption at 2800 \AA. , and a reddish-brown viscous residue (1.5 g.) (Found: C, 71.15; H, 9.95; S, 18.75; $\cdot\text{SH}$, 0.3; I.V., 260 ± 15 ; M , 825. $\text{C}_{60}\text{H}_{100}\text{S}_6$ requires C, 71.1; H, 9.95; S, 18.95%; M , 1013). A 10% aqueous solution of sodium sulphite removed 9% of the sulphur contained in the residue in 3 hrs. at 100° , but was without action on the sulphur in the distillate. A sample of the residue was heated in a vacuum for 45 mins. at 160° (Found: C, 70.9; H, 9.9; S, 18.7; $\cdot\text{SH}$, 0.9%; I.V., 209). Further molecular distillation of the distillate at 110° yielded fractions respectively poorer (Found: S, 1.2%)

and richer (Found : S, 4.8%; *M*, 415) in the sulphurated component. The former of these two fractions yielded substantially pure squalene, n_D^{20} 1.4988 (Found : S, 0.4%; I.V., 360) on passage through chromatographic alumina on which the sulphurated component was strongly adsorbed.

Squalene (10 g.), sulphur (1.0 g.), zinc oxide (0.5 g.), stearic acid (0.5 g.), and mercaptobenzthiazole (0.1 g.) were heated together for 3 hrs. at 140°. Separative treatment in the molecular still yielded a distillable component (8.4 g.), n_D^{20} 1.5109 (Found : C, 83.15; H, 11.6; S, 5.3; active H, <0.01; I.V., 312; *M*, 413. Calc. for 73% $C_{30}H_{50}S$ + 27% $C_{30}H_{50}$: C, 83.1; H, 11.7; S, 5.3%; I.V., 311; *M*, 434) and a residue (1.0 g.) (Found : S, 19.95%) which was free from zinc.

This paper forms part of a programme of fundamental research undertaken by the Board of the British Rubber Producers' Research Association. The author expresses his thanks to Dr. E. H. Farmer for his advice and criticism.

302. *The Reaction of Sulphur and Sulphur Compounds with Olefinic Substances. Part IV. The Thermal Decomposition of Organic Polysulphides, and its Contribution to the Sulphur-Olefin Reaction.*

By GEORGE F. BLOOMFIELD.

At temperatures in the region of 140° organic polysulphides undergo disproportionation resulting from thermal fission of S-S bonds and recombination of the fission products. In the presence of olefins a considerable proportion of the fission products become attached to ethylenic centres of the olefin, forming mixed mono- and poly-sulphides. The major part of the monosulphide product is fully saturated, hydrogen-capture occurring during, or subsequent to, the formation of adducts from the olefin and sulphurated fragments; unsaturation, however, appears in the polysulphide portion. The polysulphides are capable of producing monothio-cross-links between the original olefinic molecules only in so far as they are able to yield up elementary sulphur to the olefin, and when the original olefin is a polyisoprene the tendency towards the formation of a high proportion of intramolecular cyclic sulphide still further reduces the opportunity for formation of intermolecular sulphur-cross-linked products.

SINCE polysulphides are the principal products of the reaction of sulphur with olefins (Farmer and Shipley, Part I, this vol., p. 1519) an understanding of their thermal stability and of their further reaction with olefins is clearly of importance in clarifying the general problem of chemical changes associated with the olefin-sulphur reaction and the related problem of rubber vulcanisation.

The structure of polysulphides has long presented difficulty in respect of the necessity for deciding between their representation by the wholly linear structures (I) or by co-ordinated structures of type (II) or (III). Based principally on evidence provided by X-ray data (Katz,

Trans. Faraday Soc., 1936, **32**, 77) and by the lability of a considerable proportion of the sulphur atoms on treatment with alkali (Patrick, *ibid.*, p. 347) or with sodium sulphite (Parker, *India Rubber J.*, 1945, **108**, 387), a co-ordinated structure has been generally assigned to those polysulphides obtained by the interaction of organic halides and alkali polysulphides. Evidence based on the lability of sulphur atoms is, however, no certain criterion of the presence of co-ordinated sulphur atoms, since it is now shown that a comparable lability is exhibited by two of the four sulphur atoms in tetrasulphides obtained by the interaction of thiols and sulphur monochloride. Whether one accepts a linear (IV) or branched (V) structure for sulphur monochloride, it follows that three of the four sulphur atoms of the derived tetrasulphide must be in a linear chain, so that when two sulphur atoms are removed, at least one of them must have been abstracted from a linear chain. The electron-diffraction investigations of Palmer (*J. Amer. Chem. Soc.*, 1938, **60**, 2360) indicate the linear structure (IV) for the monochloride, and since, moreover, a recent ultra-violet absorption study by Koch (in the press) provides convincing evidence of a linear structure of some of the organic polysulphides which form the basis of the present work, it seems fully justifiable to assume linear structures both for the tetrasulphides prepared by the interaction of thiols with sulphur monochloride and for the polysulphide products of the sulphur-olefin reaction. The chemical behaviour of these poly-

sulphides is not at variance with the assumption of a linear structure, nor is a linear structure inconsistent with the ring formulation of the polymeric organic polysulphides (Fuller, *Chem. Reviews*, 1940, **26**, 160).

The precise mechanism of the removal of sulphur from polysulphides by sodium sulphite or sodium hydroxide is not altogether clear, although when the former reagent is used it appears certain that the polysulphide is converted mainly into disulphide (Armstrong, Little, and Doak, *Ind. Eng. Chem.*, 1944, **36**, 628) although a small proportion (not exceeding 10%) of it undergoes reduction to thiols. Probably there is fission of the sulphur chain, giving thio-radicals which recombine to form disulphides, or, to a small extent, are reduced to thiols, while the sulphur liberated converts sodium sulphite into thiosulphate.

Although the thermal decomposition at 170–180° of some polysulphides containing olefinic unsaturation gives thiols and hydrogen sulphide, together with a sulphurated product of much reduced hydrogen content (Farmer and Shipley, Part I), it is now found that the thermal decomposition of a saturated tetrasulphide at somewhat lower temperatures (140–150°) gives only disproportionation products (lower and higher polysulphides), neither thiol nor hydrogen sulphide being formed. Moreover, at temperatures below 120°, the tetrasulphides could generally be distilled unchanged.

Interaction of a polysulphide $R \cdot S_x \cdot R$ with cyclohexene in the temperature range 140–180° gave sulphurated products of the type $R \cdot S_y \cdot R'$ ($y < x$) in which R was an organic group from the original polysulphide and R' was cyclohexyl or cyclohexenyl, together with disulphides R_2S_2 derived from the original polysulphide, and cyclohexyl cyclohexenyl di- and poly-sulphides. The latter were similar to the polysulphides resulting from the reaction of sulphur itself with cyclohexene, but contained a smaller sulphur chain. Diethyl tetrasulphide and cyclohexene yielded rather complex mixtures in which the more volatile components could not be adequately separated by distillation, so it was not possible to confirm or to exclude the presence of either the cyclohexanethiol or the cyclohexene episulphide expected from the work of Jones and Reid (*J. Amer. Chem. Soc.*, 1938, **60**, 2452). The presence of some cyclohexyl ethyl sulphide was, however, established beyond doubt by the isolation of cyclohexyl ethyl sulphone on oxidation of the most volatile portion of the reaction product. When polysulphides containing larger organic groups were used, the separation of volatile components was facilitated, although the separation of non-volatile components became correspondingly more difficult. In spite of the most careful search, cyclohexene episulphide could in no case be detected, and the total amount of cyclohexanethiol formed, together with thiols derived from the original polysulphide, was extremely small. The most volatile products in every instance consisted of mixed mono-sulphides of the type $C_6H_{11}S \cdot R$, R being an organic group of the original tetrasulphide, although when di-*p*-chlorophenyl tetrasulphide reacted with cyclohexene some dicyclohexyl sulphide was formed in addition to *p*-chlorophenyl cyclohexyl sulphide. The origin of the dicyclohexyl sulphide in the latter case is obscure.

Unsaturated polysulphides obtained by reaction of sulphur with cyclohexene reacted at 140° with further cyclohexene to give polysulphides with shorter sulphur chains, separable into components none of which appeared to be of greater sulphur chain-length than a tetrasulphide, with an increasing tendency towards saturation in the more volatile components. The amount of material available did not, however, permit of the isolation of a monosulphide.

It is accordingly suggested that the thermal decomposition of polysulphides at temperatures below 180° involves thermal fission of $-S-S-$ bonds. In the absence of a second reactive substance, recombination of fission products regenerates the polysulphides or gives disproportionation products by union of dissimilar fission products. In the presence of an olefin the fission products (or the thiols derived therefrom by hydrogen capture) may either add to the ethylenic linkage, forming, ultimately, a saturated sulphide, or the fission product may link with an allylic radical to form an unsaturated mono-, di-, or poly-sulphide. Simultaneously, reaction occurs between the olefin and sulphur liberated from the sulphur chain of the polysulphide, and since the sulphur may be presumed to be liberated in a rather reactive (possibly atomic) form, the length of the sulphur chain in these products is not large.

It follows that in the reaction of sulphur with olefins, secondary products resulting from the reaction of primarily-formed polysulphides with the olefins are to be expected, especially when the olefin is present in considerable excess. When polysulphides reacted with dihydromyrcene, a considerable quantity of dihydromyrcene cyclic sulphide, identical with that obtained from dihydromyrcene and sulphur (Farmer and Shipley, Part I), was formed. Of particular interest from the point of view of the general reaction of sulphur with polyisoprenes is the ready formation of the cyclic sulphide when dihydromyrcene polysulphide itself was heated with dihydro-

myrcene, and it is hoped soon to ascertain whether the cyclic sulphide formed in the reaction of polyisoprenes with sulphur is a primary product of the olefin-sulphur reaction, or a secondary product formed solely by interaction of polyisoprene polysulphides with the excess of hydrocarbon usually present in these reactions.

Since it is now generally accepted that rubber vulcanisation requires the presence of intermolecular cross-linkages, the combination with rubber of sulphurated fragments of polysulphides alone should not cause vulcanisation unless the sulphurated fragments are themselves polyfunctional (cf. Patrick, U.S.P. 2,235,621). Dialkyl tetrasulphides react fairly readily with rubber, giving *soluble* products containing 2 or 3 units % of combined sulphur which is undoubtedly contained in sulphurated polysulphide fragments added at ethylenic centres of the rubber, since it is well established that products of the reaction of sulphur with rubber, containing considerably less combined sulphur, are quite insoluble. Both the H:C ratio and loss of unsaturation in these tetrasulphide-rubber reaction products are consistent with the postulated incorporation of sulphurated fission products with the rubber; moreover, the product of interaction of di-*p*-chlorophenyl tetrasulphide with rubber contains chemically-combined chlorine as well as sulphur. The insolubility of the latter product is attributed to the presence of sulphur in excess of that resulting from simple addition of sulphurated polysulphide fragments, and it appears certain that some degree of cross-linking has been brought about by the reaction of sulphur itself, liberated from the sulphur chain of the polysulphide. These ideas are consistent with Throdahl and Beavers's observation (*Rubber Chem. Tech.*, 1945, **18**, 110) that, although dialkyl tetrasulphides are incapable of vulcanising rubber, yet some degree of vulcanisation is observed with certain aromatic polysulphides.

It is known that in dehydrogenation reactions at elevated temperatures disulphides are as effective as sulphur itself, the disulphide linkage undergoing cleavage (Ritter and Sharpe, *J. Amer. Chem. Soc.*, 1937, **59**, 2351). If thermal dissociation of disulphides into RS· radicals (cf. Schönberg, *Ber.*, 1933, **66**, 1932) is appreciable at 140°, then it might be expected that disulphides in the presence of sulphur and an olefin would react essentially as polysulphides, and, furthermore, disulphides themselves might be expected to enter into reaction with olefins. Only scanty evidence of the latter type of reactivity has been obtained with disulphides at temperatures below 180°, and diphenyl disulphide, which might be expected to dissociate rather more readily than dialkyl disulphides, proved to be entirely without action on cyclohexene at 180°. Farmer and Shipley have, however, observed the formation of considerable amounts of mercaptobenzthiazole on heating together benzthiazole disulphide and cyclohexene at 140°. Diethyl disulphide and sulphur, heated together at 140–150°, gave no more than trace amounts of polysulphide, and when there was also an olefinic substance present reaction occurred exclusively between the sulphur and the olefin, giving the usual polysulphide products, without any indication of participation of the dialkyl disulphide.

EXPERIMENTAL.

Microanalyses were carried out by Dr. W. T. Chambers, Miss E. Farquhar, and Miss H. Rhodes. Olefinic unsaturation was determined by bromine addition (Bloomfield, *J. Soc. Chem. Ind.*, 1945, **64**, 274).

All the experiments with polysulphides were conducted in sealed glass tubes or glass flasks.

Preparation of Tetrasulphides.—Tetrasulphides were prepared by a modification of the method described by Bezzi (*Gazzetta*, 1935, **65**, 693). A 10% solution of sulphur monochloride (1 mol.) in carbon disulphide was added at room temperature to a 10% solution of the appropriate thiol (2.1 mols.) in the same solvent, and as soon as the initial brisk evolution of hydrogen chloride had subsided the solution was gently boiled for 30 minutes under a reflux condenser. The solvent was then removed at room temperature under reduced pressure, and, with the exception of di-*p*-chlorophenyltetrasulphide, which crystallised from the residue, the residual tetrasulphide was finally distilled.

Properties of Tetrasulphides.—Diethyl (sample A) had b. p. 58–60°/0.1 mm., n_D^{20} 1.6172; di-*n*-butyl was molecularly distilled at 56° in a falling-film molecular still (Farmer and Sutton, *J. Soc. Chem. Ind.*, 1946, **65**, 164) and had n_D^{20} 1.5772; diisooamyl, molecularly distilled at 56°, had n_D^{20} 1.5542; dicyclohexyl, molecularly distilled at 100°, had n_D^{20} 1.6050 (Found: C, 49.0; H, 7.45; S, 43.3. $C_{12}H_{22}S_4$ requires C, 48.95; H, 7.55; S, 43.5%); diphenyl, molecularly distilled at 110°, had n_D^{20} >1.7; di-*p*-chlorophenyl, recrystallised from light petroleum, had m. p. 57° (Found: C, 40.65; H, 2.35; Cl, 20.3; S, 36.25. $C_{12}H_8Cl_2S_4$ requires C, 41.05; H, 2.30; Cl, 20.2; S, 36.5). The author is also indebted to Dr. F. W. Shipley for a sample (B) of diethyl tetrasulphide, b. p. 45°/0.01 mm., n_D^{20} 1.610, prepared by interaction of ethyl iodide and sodium tetrasulphide. The proportion of the total sulphur content (hereinafter designated "removable sulphur") removable by a boiling 10% aqueous solution of sodium sulphite was determined for each of these tetrasulphides (Table I).

Thermal Decomposition of Dicyclohexyl Tetrasulphide.—The tetrasulphide (17.1 g.) in purified cyclohexane (50 c.c.) was heated for 4 hrs. at 140°, air being excluded. Molecular distillation of the solvent-free product yielded a relatively small amount (2.9 g.) of material of reduced sulphur content which had n_D^{20} 1.5816 (Found: C, 53.7; H, 8.35; S, 38.0; removable S, 3 hrs., 25.2, 8 hrs., 31.8%), a considerable amount (9.6 g.) of mainly unchanged dicyclohexyl tetrasulphide, n_D^{20} 1.6032 (Found: C, 49.75;

TABLE I.

H, 7.55; S, 42.3; removable S, 3 hrs., 9.2; 8 hrs., 37.2%, and a relatively small amount (1.7 g.) of viscous *dicyclohexyl hexasulphide*, n_D^{20} 1.664 (Found: C, 39.8; H, 6.15; S, 53.7; removable S, 3 hrs., 43.2, 8 hrs., 49.2. $C_{12}H_{22}S_6$ requires C, 40.2; H, 6.2; S, 53.6%). The infra-red spectrum of the hexasulphide revealed no unsaturation.

Reaction of Tetrasulphides with Olefins.—(1) *Diethyl tetrasulphide and cyclohexene*. The tetrasulphide (sample A, 20 g.) and cyclohexene (50 c.c.) were heated together for 4 hrs. at 140° in the absence of air. After removal of unchanged cyclohexene (34 g.), the product was separated into a wide range of fractions, b. p. 35–75°/0.1 mm. (total weight 18 g.), leaving a viscous residue (6 g.), care being taken to avoid heating above 130° during the distillation. The recovered cyclohexene contained a trace of ethanethiol, but no carbon disulphide could be detected. Redistillation of the volatile portion of the reaction product gave the following main fractions: (i) b. p. 75–77°/13 mm. (3.5 g.), n_D^{17} 1.5304 (Found: C, 46.05; H, 8.55; S, 46.0; removable S, 2 hrs., 25.9%); (ii), b. p. 77–79°/13 mm. (2.4 g.), n_D^{17} 1.5388 (Found: C, 42.35; H, 8.05; S, 48.95; removable S, 2 hrs., 28.8%); (iii) b. p. 79°/13 mm. (1.4 g.), n_D^{17} 1.5490 (Found: C, 38.4; H, 8.25; S, 53.4; removable S, 2 hrs., 30.5%), and (iv) b. p. 55–75°/0.1 mm. (8.4 g.), n_D^{17} 1.5970 (Found: C, 34.7; H, 6.4; S, 59.3; removable S, 2 hrs., 47.3%). Further fractionation of fraction (iv) gave sub-fractions of unchanged *n*. Since the H : C ratio of fractions (i), (ii), and (iv) indicated the presence of a considerable proportion of cyclohexyl groups, the most volatile fraction (i) was reduced by sodium in alcohol, whereby di- and poly-sulphides were converted into sodium mercaptides. Oxidation with acid permanganate of the alkali-insoluble components of the reduced product gave cyclohexyl ethyl sulphone, m. p. 34° (Found: C, 54.55; H, 9.30; S, 18.1. $C_8H_{16}O_2S$ requires C, 54.55; H, 9.15; S, 18.2%). The non-volatile portion of the original reaction product contained mainly cyclohexyl and cyclohexenyl groups (Found: C, 38.6; H, 5.7; S, 54.5; removable S, 4 hrs., 51%). Only a trace of cyclohexanethiol was detected in the reaction product, and no cyclohexene episulphide was isolated.

(2) *Diisoamyl tetrasulphide and cyclohexene*. The tetrasulphide (17 g.) and cyclohexene (50 c.c.) were heated together for 4 hrs. at 180° in the absence of air. Distillation of the reaction product yielded (a) unchanged cyclohexene (25 c.c.), (b) a fraction, b. p. 60–75°/0.01 mm. (21.2 g.), and (c) a residue (15.7 g.) not distillable below 100°/0.01 mm. The unchanged cyclohexene was carefully redistilled (Fenske column) and the residue was united with traces of liquid of b. p. <60°/0.01 mm. isolated during the preliminary separation; the combined liquids (0.5 g.), redistilled at 13 mm., consisted entirely of thiols (Found: C, 64.8; H, 10.4; S, 24.8; active H, 0.75% = 24.0% S as $-SH$). Fraction (b) was redistilled at 0.1 mm., and yielded mainly cyclohexyl isoamyl sulphide (12.5 g.), b. p. 58–60°, n_D^{20} 1.4860 (Found: C, 70.2; H, 11.6; S, 18.2; removable S, nil. Calc. for $C_{11}H_{22}S$: C, 71.0; H, 12.0; S, 17.2%), together with the following fractions of higher sulphur content: (i) b. p. 60–62° (2.7 g.), n_D^{20} 1.4909 (Found: C, 69.75; H, 11.45; S, 18.75%); (ii) b. p. 62–65° (0.6 g.), n_D^{20} 1.6018; (iii) b. p. 65–70° (2 g.), n_D^{20} 1.5142 (Found: C, 68.55; H, 10.7; S, 20.5%); and (iv) b. p. 70–75° (2.2 g.), n_D^{20} 1.5218 (Found: C, 65.25; H, 10.2; S, 24.4; removable S, 3 hrs., 12%; *M*, 198; *I. V.*, 46). Permanganate oxidation of the bulk fraction of cyclohexyl isoamyl sulphide gave the sulphone (yield, 60%), m. p. 57–58° (Found: C, 60.25; H, 10.2; S, 14.7%. Calc. for $C_{11}H_{22}SO_2$: C, 60.5; H, 10.2; S, 14.65%), which had mixed m. p. 57° with an authentic specimen of m. p. 57° (Cunneen, this vol., p. 36). The non-distillable residue (c) was passed through the molecular still at 56°, at which temperature about half of the material was volatile. The distillate (6.3 g.), a pale yellow mobile oil, had n_D^{20} 1.5458, and consisted mainly of disulphides (Found: C, 63.8; H, 9.55; S, 26.85; removable S, 8 hrs., 1.5%; *M*, 215). The brown, rather viscous residue (6.1 g.), n_D^{20} 1.5818, was of greater molecular complexity (Found: C, 61.35; H, 8.4; S, 30.0; removable S, 8 hrs., 10.7%; *M*, 318). Infra-red examination of both distillate and residue showed the presence of isoamyl groups, and also revealed the presence of unsaturation of an apparently conjugated type.

A similar experiment conducted at 140° with 12.7 g. of the tetrasulphide gave no cyclohexene episulphide and no more than a trace of thiols. Some cyclohexyl isoamyl sulphide (2.9 g.) was isolated from the crude reaction product; on passing the remainder through the molecular still the volatile portion (7.4 g.), containing considerable unchanged diisoamyl tetrasulphide, had n_D^{20} 1.5481 (Found: C, 48.05; H, 8.55; S, 43.1; removable S, 3 hrs., 37.0; 8 hrs., 43.5%; *M*, 250), but the non-volatile residue (2.1 g.) had n_D^{20} 1.5958 and probably consisted mainly of cyclohexyl isoamyl polysulphide and cyclohexenyl isoamyl polysulphide (Found: C, 43.35; H, 7.0; S, 48.3; removable S, 3 hrs., 45.2; 8 hrs., 53.0%; *M*, 312. Calc. for $C_6H_{11}S_{2.5}C_6H_{10.5}$: *M*, 301). The high proportion of removable sulphur after 3 hrs. at 100° indicates the absence of any appreciable amount of dicyclohexyl tetrasulphide. Treatment of the non-volatile residue with further cyclohexene for 3 hrs. at 140° gave an increase in weight of 23%, and pot-still molecular distillation of the product gave two fractions of substantially lower sulphur content than the original material; the distillate had n_D^{20} 1.5358 (Found: C, 56.7; H, 9.3; S, 33.85; removable S, 3 hrs., 28.7; 8 hrs., 30.7%, corresponding to $C_6H_{11}S_{2.5}C_6H_{10.5}$) and the residue had n_D^{20} 1.6062 (Found: C, 48.95; H, 7.4; S, 42.8; removable S, 3 hrs., 29.7; 8 hrs., 39.2%, corresponding to $C_6H_{11}S_{3.5}C_6H_{10.5}$).

(3) *Dicyclohexyl tetrasulphide and cyclohexene*. 9.2 G. of the tetrasulphide, heated for 3 hrs. at

180° with excess of cyclohexene, gave 9 g. of dicyclohexyl sulphide free from unsaturation (Found: C, 72.7; H, 11.2; S, 16.2. Calc. for $C_{12}H_{22}S$: C, 72.7; H, 11.15; S, 16.15%), together with higher sulphides containing unsaturation, e.g., a disulphide (5.8 g.), b. p. >100°/0.01 mm., n_D^{20} 1.5792 (Found: C, 61.6; H, 8.75; S, 29.3%). Oxidation of the dicyclohexyl sulphide gave dicyclohexyl sulphone, m. p. 132.5°, in 80% yield (Found: C, 62.4; H, 9.7; S, 13.65. Calc. for $C_{12}H_{22}O_2S$: C, 62.55; H, 9.65; S, 13.9%).

(4) *Di-p-chlorophenyl tetrasulphide and cyclohexene.* The product obtained by heating together the tetrasulphide (23.6 g.) and cyclohexene (50 c.c.) was separated by one passage through the molecular still at 56° into a pale yellow distillate (A, 14.8 g.) and a golden brown residue (B, 25 g.) which on a second passage through the still at 80° was further separated into a pale yellow distillate (C, 16.0 g.) and a residue (D, 7.3 g.). The distillate A, which had n_D^{20} 1.5661 (Found: C, 65.9; H, 7.8; Cl, 11.25; S, 15.05%), was redistilled from a flask at 0.001 mm., giving the following fractions: (i) b. p. 72–80° (0.8 g.), n_D^{20} 1.5252; (ii) b. p. 80–85° (2.0 g.), n_D^{20} 1.5342 (Found: C, 70.75; H, 9.95; Cl, 3.9; S, 15.3. Calc. for 24.6% $C_{12}H_{18}ClS$ + 73.4% $C_{12}H_{22}S$: C, 69.0; H, 9.80; Cl, 3.9; S, 15.3%), (iii) b. p. 85–92° (2.7 g.), n_D^{20} 1.5541 (Found: C, 68.45; H, 8.7; Cl, 7.9; S, 15.05. Calc. for 50.5% $C_{12}H_{18}ClS$ + 49.5% $C_{12}H_{22}S$: C, 68.05; H, 8.9; Cl, 7.9; S, 15.1%), (iv) b. p. 92–96° (4.1 g.), n_D^{20} 1.5762 (Found: C, 65.3; H, 7.05; Cl, 13.95; S, 14.4. Calc. for 89.2% $C_{12}H_{18}ClS$ + 10.8% $C_{12}H_{22}S$: C, 64.5; H, 7.1; Cl, 13.95; S, 14.3%), and a liquid residue (v), not distillable without overheating, n_D^{20} 1.5808, from which crystallised *p-chlorophenyl cyclohexyl sulphide*, m. p. 25° (Found: C, 63.85; H, 6.8; Cl, 15.75; S, 14.05. $C_{12}H_{18}ClS$ requires C, 63.55; H, 6.7; Cl, 15.65; S, 14.1%). Oxidation of fraction (iv) gave a 62% yield of *p-chlorophenyl cyclohexyl sulphone*, m. p. 68–69° (Found: C, 55.9; H, 5.85; Cl, 13.95; S, 12.4. $C_{12}H_{18}O_2ClS$ requires C, 55.7; H, 5.85; Cl, 13.7; S, 12.4%).

(5) *cycloHexyl cyclohexenyl polysulphide and cyclohexene.* A typical polysulphide (Found: C, 34.55; H, 4.85; S, 59.6%), obtained by the action of sulphur on cyclohexene, was heated with an excess of cyclohexene for 3 hrs. at 140°. There was a weight increase of 14% and the product yielded a distillate (pot still) which had n_D^{20} 1.5805 (Found: C, 56.1; H, 8.1; S, 36.15; removable S, 8 hrs., 33.2%) and a residue which had n_D^{20} 1.6260 (Found: C, 51.0; H, 7.0; S, 40.9; removable S, 8 hrs., 29.6%).

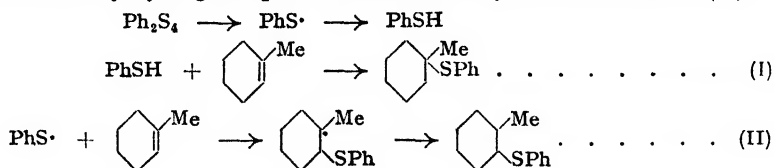

(6) *Diphenyl tetrasulphide and dihydromyrcene.* The tetrasulphide (19.1 g.) and dihydromyrcene (50 c.c.), heated together for 3 hrs. at 150° in the absence of air, yielded dihydromyrcene cyclic sulphide (3.8 g.) and a reddish-brown oil (29.7 g.) which was separated by passage through the molecular still at 80° into a volatile red liquid (21.7 g.) (Found: C, 72.4; H, 7.9; S, 18.7%) which deposited considerable diphenyl disulphide, and a brown viscous residue (4.0 g.) (Found: C, 61.85; H, 7.45; S, 31.7%).

(7) *Dihydromyrcene polysulphide and dihydromyrcene.* The polysulphide (5.5 g.), obtained by the action of sulphur on dihydromyrcene, and freed from cyclic sulphide and free sulphur by repeated passage through the molecular still, was heated with dihydromyrcene (20 c.c.) for 3 hrs. at 145° and yielded 3.3 g. of dihydromyrcene cyclic sulphide together with 6.5 g. of non-volatile matter (Found: C, 57.35; H, 8.6; S, 33.35%).

(8) *Tetrasulphides and rubber.* The tetrasulphides were incorporated into the rubber by milling, the mixtures were heated in sealed evacuated tubes for 3 hrs. at 140°, and the products were extracted with acetone and with chloroform if they were sufficiently insoluble. Diethyl tetrasulphide (0.76 g.) and rubber (5 g.) yielded a reddish-brown product (Found: C, 84.8; H, 11.65; S, 2.8%; I.V., 328) which was soluble in benzene and in chloroform. Di-*p-chlorophenyl tetrasulphide* (1.1 g.) and rubber (4 g.) yielded an insoluble product (Found: C, 79.1; H, 10.45; Cl, 2.65; S, 7.25%).

This paper forms part of a programme of fundamental research undertaken by the Board of the British Rubber Producers' Research Association. The author expresses his thanks to Dr. E. H. Farmer for his advice and criticism, and to Mr. N. Sheppard for infra-red examination of some of the polysulphides.

Note added in Proof.—Since the above papers were submitted the reaction mechanism involved in the formation of saturated monosulphides by the interaction of polysulphides with olefins has been clarified by a study of the reaction of diphenyl tetrasulphide with 1-methylcyclohexene. Since the major reaction product is phenyl 1-methylcyclohexyl sulphide and not phenyl 2-methylcyclohexyl sulphide it appears certain that the reaction involves hydrogen-capture by the fission product of the polysulphide and addition of the resulting thiol to the double bond by a polar mechanism (I) rather than by a radical addition of the fission product to the double bond followed by hydrogen-capture at the other ethylenic carbon atom (II).

The structure of the sulphide formed was confirmed by mixed m. p. (76°) of the corresponding sulphone with the phenyl 1-methylcyclohexyl sulphone of m. p. 76° described by Cunneen (*loc. cit.*).

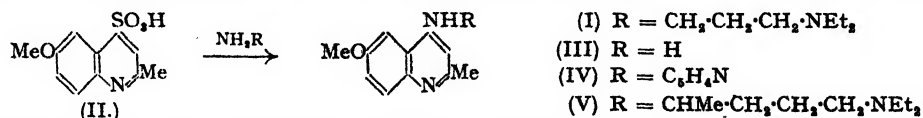

303. Derivatives of 6-Methoxyquinaldine with Basic Substituents in the 4-Position.

By JAMES WALKER.

Attention is directed to the smooth replacement of the sulphonic acid group in quinoline-4-sulphonic acids by reaction with amines as a means of preparing quinolines substituted in the 4-position by basic groups.

IN contrast with the activity shown by certain 4-dialkylaminoalkylamino-6-methoxyquinolines in bird malaria (Magidson and Rubtsov, *J. Gen. Chem. Russia*, 1937, 7, 1896), no activity was observed in analogous quinaldines (e.g., Kermack and Smith, *J.*, 1931, 3096; Krichevskii *et al.*, *J. Microbiol. Epidemiol. Immunobiol. Russia*, 1935, 14, 642). In view of the greater accessibility of the quinaldines as compared with the quinolines of this type, the present author, towards the end of 1941, began a further investigation of other 6-methoxyquinaldines, but, while the work was still in progress, essentially the same project was independently covered by Holcomb and Hamilton (*J. Amer. Chem. Soc.*, 1942, 64, 1309), who actually record the observation of antimalarial activity in 4- γ -diethylaminopropylamino-6-methoxyquinaldine (I), and the writer's interest was then withdrawn from this topic although the work, as now described below, differed in technical detail from that of Holcomb and Hamilton. In the interval, however, much attention has been devoted to the subject of quinolines substituted in the 4-position by basic side-chains in view of the marked antimalarial properties of resochin (7-chloro-4- δ -diethylamino- α -methylbutylaminoquinoline), which can be regarded as being derived from mepacrine by ablation of the methoxylated benzene ring, and the corresponding 3-methyl compound, sontochin (D.R.-P. 683,692; U.S.P. 2,233,970). Much has recently been published in the United States in this connection (e.g., Drake *et al.*, *J. Amer. Chem. Soc.*, 1946, 68, 1208, 1214; Tarbell *et al.*, *ibid.*, p. 1217; Carmack *et al.*, *ibid.*, p. 1220; Pearson, Jones, and Cope, *ibid.*, p. 1225; Riegel *et al.*, *ibid.*, p. 1229; Breslow *et al.*, *ibid.*, p. 1232; Elderfield *et al.*, *ibid.*, p. 1250). The method regularly used for the introduction of the aliphatic basic side-chains into the 4-position of quinolines has been to condense the appropriate 4-chloro-compounds with the appropriate amines at a high temperature, and fair yields have been reported as a rule. Occasionally, phenol has been added as a catalyst but it does not appear to have the same marked influence in the quinoline series as it has with 5-chloroacridines (cf. Magidson and Grigorowsky, *Ber.*, 1936, 69, 400). Potassium iodide has also been applied as a catalyst but there is little evidence of its efficaciousness, and glacial acetic acid has been used as a solvent in such condensations with aliphatic amines (Meyer and Drutel, *Compt. rend.*, 1936, 205, 148) although its use is more familiar with anilines (e.g., Fischer, Diepolder, and Wölfel, *J. pr. Chem.*, 1925, 109, 59).

The present paper records the use of 6-methoxyquinaldine-4-sulphonic acid (II) for this purpose in an application of a method outlined in the patent literature (D.R.-P. 615,184). In the original patent, quinoline-2- or -4-sulphonic acids were condensed with amines with or without the addition of a catalyst, such as zinc chloride, but the latter was used in the experiments described below, in which (II) has been condensed with ammonia to give 4-amino-6-methoxyquinaldine (III), with α -aminopyridine to give 4- α -pyridylamino-6-methoxyquinaldine (IV) in poor yield, with γ -diethylaminopropylamine to give (I) (characterised as the dihydrochloride), and with δ -diethylamino- α -methylbutylamine to give 4- δ -diethylamino- α -methylbutylamino-6-methoxyquinaldine (V) (characterised as the dihydrobromide). The sulphonic

acid (II) was obtained in practically quantitative yield from 4-chloro-6-methoxyquinaldine and sodium sulphite in aqueous solution (cf. Besthorn and Geisselbrecht, *Ber.*, 1920, 53, 1017), and subsequent condensation with amines proceeded as a smooth homogeneous reaction affording products which readily crystallised in the crude state (cf. Bachman and Cooper, *J. Org. Chem.*, 1944, 9, 307). Holcomb and Hamilton (*loc. cit.*) failed to isolate a satisfactory condensation product from 4-chloro-6-methoxyquinaldine and α -aminopyridine, but a small yield of the expected product was readily isolated using the sulphonic acid. Furthermore, condensation with ammonia proceeded particularly readily with the sulphonic acid in marked contrast with

the behaviour of 4-chloroquinolines (cf. Elderfield *et al.*, *loc. cit.*; Backeberg and Marais, *J.*, 1942, 381).

Tests for therapeutic activity in *P. relictum* infections in canaries were kindly carried out by Dr. Ann Bishop at the Molteno Institute, Cambridge, on sodium 6-methoxyquinaldine-4-sulphonate, 4- α -pyridylamino-6-methoxyquinaldine (IV), and 4- δ -diethylamino- α -methylbutylamino-6-methoxyquinaldine (V) dihydrobromide, but no activity was detected. It is now obvious that a methyl group in the 2-position in quinolines, though not in the 3-position (cf. sontochin), has a marked dystherapeutic effect probably by presenting to the host a point of metabolic attack.

EXPERIMENTAL.

6-Methoxyquinaldine-4-sulphonic Acid (II).—Ethyl β -*p*-anisidinocrotonate (Coffey, Thomson, and Wilson, *J.*, 1936, 856) was cyclised by Limpach's technique (*Ber.*, 1931, 64, 969) and the resulting 4-hydroxy-6-methoxyquinaldine was converted into the chloro-compound in 90% yield following the method of Fischer *et al.* (*loc. cit.*). 4-Chloro-6-methoxyquinaldine (5 g.) was refluxed with an aqueous solution (40 c.c., adjusted to pH 8 with *N*-hydrochloric acid) of sodium sulphite heptahydrate (12 g.) until a homogeneous solution was obtained (3½ hours) and then for a further ¼ hour. The solution, treated with norite, was filtered and cooled, affording a copious separation of colourless prisms of the sodium salt. The free acid, precipitated by acidifying an aqueous solution of the sodium salt to Congo-red with 16% hydrochloric acid, separated from water in pale cream-coloured hydrated prisms which lost part of the water of crystallisation in a vacuum desiccator, darkened at about 296°, and had m. p. 302–303° (decomp.) (Found: C, 48.6; H, 5.0; N, 5.2. $C_{11}H_{11}O_4NS \cdot H_2O$ requires C, 48.7; H, 4.8; N, 5.2%). The yield was nearly quantitative.

4-Amino-6-methoxyquinaldine (III).—6-Methoxyquinaldine-4-sulphonic acid (6 g.), 25% aqueous ammonia solution (30 c.c.), and zinc chloride (1 g.) were heated in a sealed tube at 130° for 20 hours. On cooling, large yellow plates were deposited. The mixture was warmed to effect solution, cooled, and treated with excess of 2*N*-sodium hydroxide (25–30 c.c.). The precipitated oil rapidly crystallised in colourless needles (3.75 g.; 84%), m. p. 206°. Recrystallisation from dilute aqueous alcohol afforded thin plates, m. p. 208–209° (Found: C, 70.0; H, 6.5; N, 14.9. Calc. for $C_{11}H_{12}ON_2$: C, 70.2; H, 6.4; N, 14.9%). Koenigs and v. Loesch (*J. pr. Chem.*, 1935, 143, 59) record m. p. 211–213°, and Backeberg and Marais (*loc. cit.*) record m. p. 209°.

4- α -Pyridylamino-6-methoxyquinaldine (IV).—6-Methoxyquinaldine-4-sulphonic acid (5.06 g.), freshly distilled α -aminopyridine (3.8 g.), zinc chloride (1 g.), and water (25 c.c.) were heated in a sealed tube at 140° for 30 hours. The product was distributed between ether and excess of 2*N*-sodium hydroxide. The ether was well washed with water, dried, and evaporated, affording a cream-coloured solid (0.33 g.; 6.2%), which separated from benzene in rosettes of fine colourless prisms, m. p. 196–197° (Found: C, 72.6; H, 5.7; N, 15.5. $C_{16}H_{14}ON_2$ requires C, 72.5; H, 5.7; N, 15.8%).

4- γ -Diethylaminopropylamino-6-methoxyquinaldine (I) Dihydrochloride.—6-Methoxyquinaldine-4-sulphonic acid (5.06 g.), γ -diethylaminopropylamine (4.3 g.), zinc chloride (1.2 g.), and water (18 c.c.) were heated in a sealed tube at 140° for 24 hours. The product was distributed between ether and 3*N*-sodium hydroxide. The ethereal solution was well washed with water, dried, and evaporated, affording a stiff pale yellow syrup which crystallised completely in the form of transparent plates (4.26 g.; 71%); the solid did not remelt on the boiling water-bath. The base was dissolved in a small volume of warm alcohol and treated with the calculated volume of alcoholic hydrochloric acid. The dihydrochloride, obtained on evaporation, separated from ethyl alcohol–ethyl acetate (1 : <1) in minute clusters of colourless prisms, m. p. 134° (Found, in material dried over sulphuric acid in a vacuum: C, 53.7, 54.2; H, 7.9, 7.8; N, 10.5. $C_{18}H_{27}ON_3 \cdot 2HCl \cdot 1½H_2O$ requires C, 53.9; H, 8.0; N, 10.5. Calc. for $C_{18}H_{27}ON_3 \cdot 2HCl \cdot 2H_2O$: C, 52.7; H, 8.0; N, 10.2%). Holcomb and Hamilton (*loc. cit.*) obtained a dihydrate, and record m. p. 126–127°; Van Arendonk and Shonle (*J. Amer. Chem. Soc.*, 1944, 66, 1284) record m. p. 125–126°.

4- δ -Diethylamino- α -methylbutylamino-6-methoxyquinaldine (V) Dihydrobromide.—6-Methoxyquinaldine-4-sulphonic acid (7.6 g.), δ -diethylamino- α -methylbutylamine (9.6 g.), zinc chloride (1 g.), and water (20 c.c.) were heated in a sealed tube at 150° for 20 hours. The product was isolated as in the preceding case and the base, obtained initially as an amber syrup (6.6 g.; 67%), rapidly crystallised, affording a cream-coloured solid, m. p. 120–122°, clearing at 123° (Found: OMe, 9.5. $C_{26}H_{33}ON_2$ requires OMe, 9.4%). The dihydrobromide, obtained by neutralisation with the calculated volume of *N*-hydrobromic acid and evaporation to dryness, separated from ethyl alcohol–ethyl acetate (approx. 1 : 2) in clusters of colourless radiating prisms, m. p. 197–198° (Found: C, 48.7; H, 6.7; N, 8.4; Br, 32.3. $C_{26}H_{33}ON_2 \cdot 2HBr$ requires C, 48.9; H, 6.7; N, 8.6; Br, 32.6%). The dihydrochloride of this base has been described by Holcomb and Hamilton (*loc. cit.*).

The author is greatly indebted to Dr. Ann Bishop for carrying out the antimalarial tests and to Mr. L. V. Sharp for assistance in the preparation of starting materials.

304. *Strychnine and Brucine. Part XLVII. Oxodihydroneostrychnine and Oxodihydromethoxymethyl dihydroneostrychnine.*

By R. N. CHAKRAVARTI, K. H. PAUSACKER, and SIR ROBERT ROBINSON.

It is shown that bases of the *neo*-series are characterised by facile oxidation to oxo-derivatives formed by addition of one atom of oxygen. The carbon-nitrogen skeleton of strychnine is found unaltered in reduction products of these substances.

In the course of attempts to prepare the methiodide of methoxymethyl dihydroneostrychnidine in methanolic solution it was found that oxidation occurred and the product was termed oxymethoxymethyl dihydroneostrychnidine-A, m. p. 235°. It was convertible into an isomeride-B, m. p. 280° (285°), in various ways, for example by boiling with xylene or acetone (Clemo, Perkin, and Robinson, J., 1927, 1608). No semicarbazone could be prepared, and the base was unchanged by boiling acetic anhydride. It was recognised that the methyl iodide was a source of a trace of catalytic iodine, and the brucidine analogue was obtained by the use of methanol and a crystal of iodine (Gulland, Perkin, and Robinson, J., 1927, 1643).

In a later paper (Achmatowicz, Perkin, and Robinson, J., 1932, 495), the oxidation of methoxymethyl dihydroneostrychnidine by means of potassium permanganate in acetone solution was studied. The product was an acetone compound of the oxymethoxy dihydroneostrychnidine-C, m.p. 305–306°. The opinion was expressed that (C) is (B) in purer form.

An interesting observation was the conversion of the isomeride-C into oxymethyl neostrychnidinium salts by boiling it with 20% sulphuric acid. The iodide was analysed, and the related chloride could be converted into the base-C by the action of methanolic potassium hydroxide. This was regarded as a proof that the oxygen taken up is not present in a labile group such as an ethylene oxide.

Our further observations suggest that these so-called isomerides are either very labile isomerides or owe their differing melting points to the presence of tenaciously held solvent.

Material of m. p. 285°, corresponding to isomeride-B, afforded a *p*-nitrophenylhydrazone which could not, however, be fully purified by crystallisation. It gave the characteristic colour reaction of its class with aqueous alcoholic sodium hydroxide.

The bases of m. p. 210–224° (A) and m. p. 285° (B) were converted in the known manner in oxynestrychnidine methiodide; the same product was obtained in each case and it tallied with the description (*loc. cit.*) of the salt from isomeride-C. On treatment with methanolic potassium hydroxide the latter base was produced.

An indication that the skeleton was unaltered by the oxidation was afforded by reduction of isomeride-B under Clemmensen's conditions with formation of methoxymethyl tetrahydrostrychnidine. These results suggest that the oxidation product is an aldehyde or ketone, and we propose the replacement of the prefix "oxy" by "oxodihydro". Methoxymethyl dihydroneostrychnine is found to be convertible into oxodihydromethoxymethyl dihydroneostrychnine either by leaving a methanolic solution containing a trace of iodine to evaporate in the air, or by boiling with methanol and methyl iodide. The use of ethanol led to the formation of an uncrystallisable gum. The new base holds firmly $\frac{1}{2}$ MeOH or $\frac{1}{2}$ EtOH. Although it certainly forms a *p*-nitrophenylhydrazone, this derivative showed no tendency to crystallise. The base was also oxidised by means of ferric chloride in *N*-hydrochloric acid. The crystalline product appears to have the composition $C_{44}H_{56}O_7N_8$, that is, two molecules of the base take up one atom of oxygen. A low value was obtained for the molecular weight in fused camphor, but this is probably due to fission of the molecule under the conditions of the experiment. A very satisfactory oxidation of nestrychnine occurs when its acid solution is treated with bromine water in the cold. The *hydrobromide* of oxodihydronestrychnine* crystallises in high yield. The free base exhibits interesting properties and transformations which will be described in detail in a subsequent communication. It is mentioned here because the composition change is the same as that observed in other cases and because this substance is the most characteristic of the oxodihydroneo-bases which we have encountered.

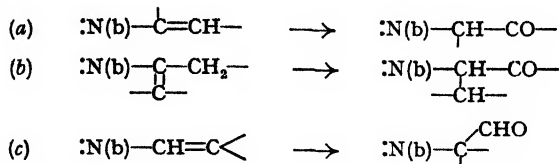

Although this and the other oxodihydro-bases reduce ammoniacal silver solutions with ease and slowly reduce Fehling's solution, it does not follow that they are aldehydes. It is well known that many α -amino-ketones are readily oxidised by the reagents mentioned.

The aldehyde hypothesis seems to be inconsistent with the reduction of oxodihydromethoxy-

* The use of *neo* in this name may be superfluous because dihydroneostrychnine is dihydrostrychnine. But this depends on the validity of our views and the *neo* is retained in order to show the origin of the base.

methylneostrychnidine to methoxymethyltetrahydrostrychnidine and with the formation of oxodihydromethoxymethylstrychnidine-C from oxodihydromethylstrychnidinium salts by the action of such a vigorous reagent as methyl alcoholic potassium hydroxide.

The only rational explanations of the formation of these oxodihydroneo-bases that we can devise are as follows :

Added May 9th, 1947.—It now seems probable that oxodihydroneostrychnidine is not analogous to the other oxo-compounds mentioned herein, and the discussion is therefore postponed.

Added November 9th, 1947.—It has been established that the salt first formed is a neo-strychnine dibromide (one bromidion) which changes to oxodihydroallostrychnine hydrobromide in warm aqueous solution. The free base is an aldehyde produced in accordance with hypothesis (c). A statement of these relations was made to the Organic Chemistry Section of the International Congress of Chemistry (London, 1947).

EXPERIMENTAL.

Oxodihydromethoxymethyldihydroneostrychnidine.—This substance was obtained by the known method (*loc. cit.*, 1927) and had variable m. ps. ranging from 210° to 224° (lit. 235°) in different runs. After addition of methanol to a solution in pyridine, the crystals that separated had m. p. 285° and the same value was reached by refluxing the initial product with ethanol or acetone. Only a small quantity of dark material remained in the filtrate.

Oxidation of methoxymethyldihydroneostrychnidine (7 g.) by means of potassium permanganate in acetone solution (*loc. cit.*, 1932) gave 0.5 g. of the variety, m. p. 305°. This separated on concentration of the acetone solution, and the bulk of the product was obtained on removal of the solvent as an uncrystallisable oil. It is very difficult to determine whether the varieties, m. p. 285° and m. p. 305°, are identical or not. The mixed m. p. was 288—294°, and when a pyridine solution of the base, m. p. 285°, was mixed with methanol containing a few crystals of the base, m. p. 305°, the separated crystals had m. p. 304—306°. On the other hand the variety, m. p. 285°, can be recrystallised without change of m. p. and no change of m. p. was observed on refluxing it with acetone, alone or in presence of a little sodium hydroxide. Conversion of any of the supposed isomerides into oxymethylneostrychnidine methiodide (*loc. cit.*) gave one and the same salt, m. p. 232—234° (lit., 238—240°) showing undepressed mixed m. ps.

The quaternary chloride from the variety, m. p. 285°, was treated with methanolic potassium hydroxide in the known manner and afforded a base, m. p. 298—300°, m. p. 300—302° on admixture with the variety, m. p. 305°.

A mixture of the variety, m. p. 285° (0.1 g.), *p*-nitrophenylhydrazine (0.04 g.), and acetic acid (2 c.c.) was heated on the steam-bath for ½ hour. Addition of aqueous ammonia precipitated a light yellow amorphous solid which was purified by solution in hot ethanol and addition of water; it could not be crystallised (Found : C, 67.9; H, 7.0. $\text{C}_{20}\text{H}_{28}\text{O}_4\text{N}_2$ requires C, 67.3; H, 6.8%). The substance softened at 120° and decomposed at 185—186° but these figures have little significance. Its alcoholic solution developed an intense red coloration on the addition of a drop of 10% aqueous sodium hydroxide, the reaction characteristic of *p*-nitrophenylhydrazones. Its acid solution developed a carmine coloration (strychnidine reaction) on addition of ferric chloride. The variety, m. p. 305°, gave a similar *p*-nitrophenylhydrazone exhibiting these reactions.

A mixture of the variety, m. p. 285° (2.0 g.), concentrated hydrochloric acid (5 c.c.), water (4 c.c.), and amalgamated zinc (5 g., prepared according to "Organic Reactions," 1, 163) was refluxed for 12 hours with the addition of further concentrated hydrochloric acid (1 c.c.) each hour. The diluted solution was basified with sodium hydroxide and the product obtained as a white solid (1.8 g., m. p. 220—221°). The substance was crystallised from benzene and from pyridine-methanol and identified as methoxymethyltetrahydrostrychnidine by observation of the m. p. 220—221°, undepressed on admixture with an authentic specimen.

Oxodihydromethoxymethyldihydroneostrychnine.—Methoxymethyldihydroneostrychnine was prepared from methylstrychnine by the method of Achmatowicz, Clemo, Perkin, and Robinson (*J.*, 1932, 769), and a consistent yield of about 75% was secured by a modification of procedure of isolation. After the removal of methanol and addition of water the alkaline solution was mixed with crushed ice and gradually acidified by acetic acid in a funnel with shaking with ether. In this way the formation of gummy by-product was avoided.

(A). Methoxymethyldihydroneostrychnine (5 g.) was dissolved in hot methanol (300 c.c.) and a small crystal of iodine added. The solution was allowed to evaporate in the air for a week. Gum was separated from the sparingly soluble crystalline crust by treatment with hot methanol, the solid was collected, and the filtrate allowed to evaporate again. By repetition of this process the yield was 1.8 g. The substance separated from pyridine-methanol as a jelly which became crystalline on warming. It is sparingly soluble in ethanol, and when the solutions were quickly cooled a gel was also formed; on slow cooling, however, the substance separated as radiating cluster of fine needles, which shrank at 225°.

m. p. 275—277° on slow heating. If heated rapidly the m. p. ranges from 230° to 240° (Found in material dried over sulphuric acid: C, 68.6; H, 7.1; N, 6.7; MeO, 11.3. $C_{23}H_{28}O_3N_2 \cdot 0.5EtOH$ requires C, 68.7; H, 7.4; N, 6.7%; 1 MeO + 0.5 EtO, Calc. as MeO, 11.1%). When ethanol was employed in this preparation no crystallisable product was obtained. The base dissolves slowly but completely in *n*-hydrochloric acid and is precipitated by the addition of sodium acetate. It forms a *p*-nitrophenylhydrazone and a 2:4-dinitrophenylsemicarbazone, but neither of these derivatives could be crystallised. The former gave an intense orange-red coloration, blue-tinged in thin layers, on the addition of potassium hydroxide to its alcoholic solution.

(B). Methoxymethylidihydroneostrychnine (4 g.) was refluxed with methyl iodide (5 c.c.) and methanol (40 c.c.) for 3 hours and then shaken in contact with air for 10 days. The separated crystals (0.6 g.) were deposited from pyridine solution by the addition of methanol as a jelly which crystallised on keeping. This specimen softened at 222°, m. p. 275—277° (Found: C, 68.5; H, 6.9. $C_{23}H_{28}O_3N_2 \cdot 0.5MeOH$ requires C, 68.4; H, 7.3%). Recrystallised from ethanol (gel \rightarrow crystals) it was obtained in needles, softening at 240°, m. p. 275—277°, and mixed with the product from (A) it softened at 235°, m. p. 275—277°. It is quite possible that the half molecule of solvent is in combination in the form $-\dot{C}(OR)-O-\dot{C}(OH)-$ and that the variations of softening points are due to incomplete exchange of R by R'. When iodine (0.2 g.) was used in place of methyl iodide in this procedure, the yield was 1.0 g. The *p*-nitrophenylhydrazone shrank at 130°, m. p. 155—157° (decomp.). Strychnine and methoxymethylidihydroneostrychnine immediately decolorise permanganate in very dilute sulphuric acid solution. Oxodihydroneostrychnine is very slowly attacked under these conditions.

Reduction according to Clemmensen afforded a base, m. p. 261—262°, readily soluble in methanol, but the investigation of this substance has not yet been completed.

Oxidation of Methoxymethylidihydroneostrychnine by Means of Ferric Chloride.—A cold solution of ferric chloride (3.3 g., anhydrous) in water (15 c.c.) was added to one of methoxymethylidihydroneostrychnine (3.8 g.) in *n*-hydrochloric acid (35 c.c.). After an hour the red solution was basified with ammonia, precipitating the base along with ferrous hydroxide. The whole was shaken with ethyl acetate (about 50 c.c.), filtered, and the ester layer separated and evaporated (2.6 g. of crystalline residue). The substance is very sparingly soluble in hot methanol or ethanol, readily soluble in dilute hydrochloric acid. It crystallises from chloroform on the addition of ether in small, flat needles, m. p. 190° (Found: C, 70.9; H, 7.1; N, 7.3; *M* (Rast in camphor), 467. $C_{23}H_{28}O_3N_4$ requires C, 71.1; H, 7.2; N, 7.2%; *M*, 776]. The composition suggests a compound of oxodihydroneostrychnine, $C_{23}H_{28}O_3N_2$, and methoxymethylidihydroneostrychnine, $C_{23}H_{28}O_3N_2$, but the substance does not afford a *p*-nitrophenylhydrazone and it gives no precipitate on the addition of *p*-nitrobenzenediazonium chloride to an acid solution. Possibly it is an ether, and the composition $C_{46}H_{56}O_7N_4$ (Calc.: C, 71.3; H, 7.0; N, 7.2%) is not excluded.

Oxodihydroneostrychnine.—A hot solution of neostrychnine (8.35 g.) in 1.5*N*-sulphuric acid (110 c.c.) was cooled to the room temperature and 0.2*N*-bromine water (250 c.c.) added in 4 to 5 portions with shaking, so that the yellow perbromide that separated was quickly decomposed. The white crystalline precipitate was collected after 15 minutes, washed with a little water, and dried in a vacuum desiccator (9.8 g.). The salt is a hydrobromide free from sulphate. Although very sparingly soluble in cold water, it dissolves readily on heating and forms supersaturated solutions. Crystallisation is best effected from concentrated solutions and seeding is necessary. The colourless, well-shaped prisms become deep red with shrinkage at 170° and gradually decompose on further heating (Found: C, 55.2, 56.0; H, 5.6, 5.7; Br, 17.3, 18.7. $C_{21}H_{22}O_3N_2 \cdot HBr \cdot H_2O$ requires C, 56.1; H, 5.6; Br, 17.8%). The free base was obtained as a chalky precipitate on addition of ammonia to a cold solution of the hydrobromide. It was collected, washed, and dried in a vacuum (7.5 g., m. p. 80—140°). This product was dissolved in methanol (80 c.c.) and the solution concentrated to 15—20 c.c. when it separated in stellate clusters of transparent prisms (6 g.), m. p. 128° (decomp.) (Found: C, 69.1; H, 6.9; N, 7.4. $C_{21}H_{22}O_3N_2 \cdot MeOH$ requires C, 69.1; H, 6.8; N, 7.3%). The solvent is lost slowly at 100°, more rapidly at near 120° (loss, 7.6. Calc.: 8.3%). The solvent-free base has m. p. 190° and is hygroscopic (Found: C, 71.6; H, 6.4; N, 7.9. $C_{21}H_{22}O_3N_2$ requires C, 72.0; H, 6.3; N, 8.0%).

It is of interest that oxodihydroneostrychnine can also be obtained, although in poor yield, by aerial oxidation of neostrychnine in methanol containing iodine. A mixture of neostrychnine (3 g.), methanol (120 c.c.), and iodine (0.2 g.) was shaken for 9 days under air. Some neostrychnine remained undissolved (1.8 g., m. p. 224—225°) and the filtrate was evaporated and the residue extracted with dilute sulphuric acid. Ammonia precipitated a white solid (0.5 g., m. p. 110° with frothing) and this was converted into the semicarbazone hydrochloride in the usual manner. The salt, when slowly heated, darkened at 240° and decomposed at 255°, and the behaviour was unchanged on admixture with the derivative prepared from oxodihydroneostrychnine. The base is sparingly soluble in the simple alcohols but has a tendency to form supersaturated solutions. It is readily soluble in chloroform and can easily be crystallised by addition of ether to a concentrated solution. It is fairly soluble in dilute hydrochloric acid. A silver mirror is formed with ammoniacal silver nitrate after heating on the steam-bath for 10 minutes, and the base also reduces silver oxide in boiling alcoholic suspension, forming a mirror. It slowly reduces Fehling's solution on heating. The Otto reaction (60% sulphuric acid) is a transient violet coloration changing to deep red and finally brown. The *p*-nitrophenylhydrazone is a yellow solid, the alcoholic solution of which becomes deep red on the addition of aqueous sodium hydroxide. Crystalline derivatives showing the presence of a carbonyl group have been prepared and analysed, but a description of these is reserved for a future communication.

The authors are grateful to the Trustees of the Palit Fund, Calcutta University, for a Scholarship awarded to one of them (R. N. C.), and also to the University of Melbourne and the Carnegie Fund for a Travelling Scholarship and a Grant, respectively, awarded to another of them (K. H. P.).

305. Strychnine and Brucine. Part XLVIII. Degradation of the Strychnineacetic Acid prepared from Pseudostrychnine.

By K. H. PAUSACKER and SIR ROBERT ROBINSON.

The alkaline degradation of strychnineacetic acid has been studied in the hope of supplying evidence in favour of one of the two structures discussed in Part XLII (Briggs, Openshaw, and Robinson, *J.*, 1946, 903). One of the products should be 3- or 4-methylcarbazole, and an unequivocal result would have been of great value. Actually the main constituent of the carbazole fraction was carbazole itself, but infra-red absorption analysis, carried out by Mr. R. E. Richards of the Physical Chemistry Laboratory, Oxford University, showed that 3-methylcarbazole, but no 4-methylcarbazole, was present in small relative amount.

The carbazole from strychnine was found to contain a trace of 3-methylcarbazole, and degradation of the product of interaction of oxodihydroneostrychnine and methylmagnesium iodide afforded a carbazole fraction containing 3-methylcarbazole and an unidentified substance.

For the study of the infra-red absorption 1-, 2-, and 3-methylcarbazoles were prepared by known methods.

4-Methylcarbazole does not appear to have been hitherto described and was synthesised without ambiguity from 4-chloro-*m*-tolylhydrazine by way of a related tetrahydrocarbazole.

CARBAZOLE was first obtained from strychnine by dry distillation and by heating with zinc dust (Lobisch and Schoop, *Monatsh.*, 1886, 7, 614); by heating strychnine with soda-lime, Lobisch and Malfatti (*ibid.*, 1888, 9, 626) obtained carbazole, skatole, and β -picoline. The formation of carbazole was confirmed by Clemo, Perkin, and Robinson (*J.*, 1927, 1625), who decomposed methylstrychnine at 150–200°. Such drastic degradations affording aromatic compounds of high intrinsic stability are admittedly of problematic value in constitutional studies, but it occurred to us that the survival of a group introduced into the strychnine molecule would be significant.

It is known that pseudostrychnine (hydroxystrychnine) contains N(b)C(OH) (Blount and Robinson, *J.*, 1932, 2305), and Leuchs (*Ber.*, 1943, 76, 1068) showed that this base condenses with malonic acid to strychnineacetic acid, $\text{N(b)C}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$, which loses carbon dioxide with formation of methylstrychnine.

Degradation of a crude product obtained in this way gave a carbazole fraction which on examination by the usual methods was found to contain methylcarbazoles in considerable relative amount (up to 40%). At this point we were fortunate to receive the valuable co-operation of Mr. R. E. Richards to whom we express our gratitude. He examined the infra-red spectra of carbazole and the four *C*-methylcarbazoles and noted the presence of certain characteristic bands. He also studied our degradation products and synthetic mixtures of carbazole and the various isomerides. The degradation product was found to contain from 5 to 12% of 3-methylcarbazole, and 4-methylcarbazole was absent.

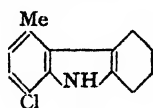

As a control we degraded strychnine by the same method, and the infra-red analysis of the product showed that it was carbazole containing a little (<1%) 3-methylcarbazole. As the 3-position is *para* to the imino-group it would not be surprising if a small amount of the homologue were synthesised by condensation reactions in the course of the process. It was also shown that a mixture of 4-methylcarbazole and carbazole afford no 3-methylcarbazole under the conditions employed, although naturally it would never be feasible to eliminate the possibility of migration of groups at an earlier stage.

Up to this point it seemed safe to conclude that N(b) is attached to position 3 of a partly reduced carbazole nucleus in the strychnine molecule. We hoped to clinch the matter by introducing a methyl group in a different position, and for this purpose selected oxodihydroneostrychnine (see the preceding paper) as the starting point. This base probably contains $\text{N(b)C}\cdot\text{CO}$, and reaction with methylmagnesium iodide should result in attachment of methyl to the β -carbon with respect to N(b). Hence the result of degradation was expected to be 4-methylcarbazole (or 2-methylcarbazole). The outcome was surprising since the carbazole fraction of the degradation product contained about 10% of 3-methylcarbazole as found by infra-red absorption analysis. Unidentified substances were also present. Now whatever the constitution of strychnine may be, it is anomalous that these two degradations should have given the same result. It is inescapable that migration must have occurred in one of the cases unless, indeed, the methyl group of 3-methylcarbazole does not arise from that introduced into the strychnine molecule. It will be seen that the clarity of an argument that could be developed is obscured by the necessity to exercise judgment in the interpretation of the results.

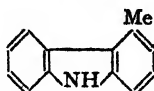

Synthesis of 4-Methylcarbazole.—According to Plancher and Carrasco [*Roy. Acad. Lincei*, 1904, (V), 18, (i), 632, cited by Hollins, "Synthesis of Nitrogen Ring Compounds," p. 168] the

Fischer reaction applied to 3-methylcyclohexanone phenylhydrazone affords a mixture of 2- and 4-methyltetrahydrocarbazole; Borsche, Bothe, and Witte (*Annalen*, 1908, 359, 61) found only the 2-methyl derivative. (Owing to a special numbering system this is described as the 4-methyl derivative, but it gives 2-methylcarbazole on dehydrogenation.) To effect an unambiguous synthesis it was preferable to start with a *m*-tolylhydrazine, and we blocked the 4-position by a chlorine atom.

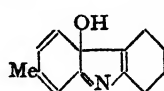

4-Chloro-*m*-toluidine (Gattermann and Kaiser, *Ber.*, 1885, 18, 1600) was converted in the usual manner into the hydrazine and then into 8-chloro-5-methyl-1:2:3:4-tetrahydrocarbazole

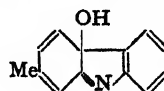

(I.)

(II.)

(III.)

(IV.)

(I) by heating with dilute sulphuric acid; a by-product is discussed below. (I) was dehydrogenated by chloranil with formation of 1-chloro-4-methylcarbazole and converted into 4-methylcarbazole (II) by heating with palladised charcoal in a stream of hydrogen.

The by-product mentioned above contained a trace of chlorine and hence gave low results for carbon. It appears, however, to be $C_{13}H_{11}ON$. It was dehydrogenated by palladised charcoal to a substance $C_{13}H_{11}ON$ which gave sharp results on analysis. These curious compounds are devoid of phenolic character and do not form picrates. The constitutions (III) and (IV) are suggested provisionally. It is hoped that an opportunity to make a further examination of these substances will be found.

Added in Proof (November 9th, 1947).—We now know that oxodihydroneostrychnine is a derivative of allostrychnine and is an aldehyd. The methyl introduced by the Grignard reagent is remote from the carbazole nucleus. Therefore the formation of 3-methylcarbazole is probably due to rearrangement or synthesis in the course of the degradation process.

EXPERIMENTAL.

Degradation of Strychnineacetic Acid.—Pseudostrychnine was prepared by the elegant method of Leuchs (*Ber.*, 1940, 73, 734) who states that strychnine (100 g.) yields crude pseudostrychnine (41–43 g.), neutral product (10–15 g.), and unchanged strychnine (30–33 g.). Our experience of several runs is that the respective average figures are 54, 20, and 4.

This crude pseudostrychnine (43 g.) was converted into strychnineacetic acid (Leuchs, *loc. cit.*) by condensation with malonic acid. The isolated perchlorate was powdered with animal charcoal and extracted with water in a Soxhlet apparatus (39 g.). On treatment with *N*-sodium bicarbonate solution (69 c.c.) and continuous extraction with chloroform, strychnineacetic acid (30 g.) was obtained. This was then heated in batches (6 g.) for 0.5 hour at 280–300°; a brown powder (25 g.) was obtained. Leuchs (*Ber.*, 1943, 76, 1069) claims that methylstrychnine can be obtained in 17–25% yield by this method. This was powdered in 5 g. lots with soda-lime (30 g.) and heated in a metal-bath at 380–400° for 1 hour. The distillate, a brown tar, was extracted with benzene, washed with acid and alkali and steam-distilled. After about 10 l. had distilled, no further volatile substances came over. The distillate was extracted with benzene, concentrated, and passed through an alumina column. The first washings were found to be light yellow and fluorescent in ultra-violet light. These were concentrated and the resultant crystals were recrystallised from light petroleum (b. p. 60–80°). After sublimation in a high vacuum at 160°, a white solid (30 mg.) was obtained. It had a faint indolaceous odour, m. p. 203–207° after shrinking at 199° (Found: C, 86.0; H, 5.9; C-Me, 3.7%). On being kept in the air it became light brown. When this substance (3 mg.) was treated with picric acid (3.6 mg.) in benzene, a red-brown picrate, m. p. 156–162°, was obtained. The white solid dissolved in concentrated sulphuric acid to a very pale yellow solution which became ultramarine blue on the addition of a drop of concentrated nitric acid. When it was dissolved in alcohol and an acid solution of *p*-nitrobenzenediazonium chloride added, a bright yellow coloration developed. Infra-red measurements indicate that the mixture contains about 8–12% of 3-methylcarbazole along with carbazole. None of the other methylcarbazoles were detected but a small amount of some impurity was also found to be present.

The following experiments were made for comparative purposes.

Carbazole. When recrystallised from benzene the specimen employed had m. p. 238° (Found: C-Me, 0.85. Calc.: C, 86.2; H, 5.4; C-Me, 0.0%). The yellow solution in concentrated sulphuric acid became ultramarine blue on the addition of a drop of concentrated nitric acid. Its solution in alcohol became pale pink on the addition of an acidified solution of *p*-nitrobenzenediazonium chloride. The picrate (bright red) had m. p. 183–184°; mixed m. p. with the unknown picrate, 157–160°. The melting points of mixtures of carbazole and 3-methylcarbazole, and of carbazole and 4-methylcarbazole are shown below:

Carbazole and 3-methylcarbazole.

Carbazole, %	4	16	27	38	52	62	79	89	95
Softening pt.	200°	198°	198°	203°	210°	213°	220°	228°	234°
M. p.	200—	199—	201—	205—	212—	214—	224—	231—	237—
	202°	201°	203°	207°	214°	217°	227°	233°	238°

Carbazole and 4-methylcarbazole.

Carbazole, %	4	13	24	36	53	62.5	75	87.5	94.5
Softening pt.	110°	110°	107°	117°	130°	175°	190°	224°	230°
M. p.	112—	113—	115—	140—	168—	198—	214—	228—	235—
	117°	117°	150°	174°	196°	220°	224°	232°	236°

A mixture of the unknown with an equal quantity of a 3-methylcarbazole-carbazole mixture (60 : 40) softened at 198° and had m. p. 202—205°.

3-Methylcarbazole. The specimen had m. p. 202° (Found: C-Me, 6.0. Calc.: C, 86.2; H, 6.1; C-Me, 8.3%). It gave a colourless solution in concentrated sulphuric acid which turned emerald green upon the addition of a drop of concentrated nitric acid. Its alcoholic solution became faintly yellow upon the addition of *p*-nitrobenzenediazonium chloride. The dark red picrate had m. p. 178—179°; mixed m. p. with the unknown picrate, 155—158°; mixed m. ps. with carbazole picrate were 158—162° (33% carbazole picrate), 160—164° (50%), 160—164° (66%).

A mixture of carbazole (20 mg.) and 3-methylcarbazole (20 mg.) could not be separated by chromatography under the conditions employed.

4-Methylcarbazole (Found: C-Me, 5.7%). The colourless solution in sulphuric acid became ultramarine blue on the addition of nitric acid. Its alcoholic solution gave a yellow-brown coloration with *p*-nitrobenzenediazonium chloride.

From these results it appears that the degradation product contains a compound, affording acetic acid in the Kuhn-Roth estimation of side-chain methyl, other than the 10% of 3-methylcarbazole indicated by the infra-red analysis. The faint indolaceous odour and the colour reactions suggest that this may be an indole derivative, but the possibility of the presence of higher homologous carbazoles cannot be dismissed.

The residue in the flask from the degradation reaction was found to contain a fluorescent acid substance. It gave the carbazole reaction with sulphuric-nitric acid but was obtained in such small quantity that further examination was precluded. When strychnine was distilled over soda-lime at 400°, carbazole, m. p. 229—232°, could be isolated in the manner described above. The specimen had the usual faint indolaceous odour and became light brown in colour on being kept for a few days. The infra-red spectrum showed strong carbazole bands at 845 cm.⁻¹ and 857 cm.⁻¹, a weak band at 810 cm.⁻¹ (3-methylcarbazole, <1%), and a very weak band at 787 cm.⁻¹, which was not found with carbazole or any of the four C-methylcarbazoles. A mixture of carbazole (60 mg.) and 4-methylcarbazole (40 mg.) was heated with soda-lime (30 g.) for an hour at 380—400°. The distillate was collected by means of acetone and sublimed, m. p. 192—217°; carbazole-4-methylcarbazole (62.5 : 37.5), m. p. 198—220°. Infra-red examination showed the presence of carbazole and 4-methylcarbazole, but the absence of 3-methylcarbazole could not be categorically affirmed because 4-methylcarbazole has a band at 812 cm.⁻¹ in the vicinity of that of 3-methylcarbazole at 808 cm.⁻¹. However in the graph obtained there was no appreciable broadening of the 812 band towards 808.

ββ-N(b)-Hydroxymethylidihydroneostrychnine.—A Grignard solution was prepared from magnesium (13 g.), methyl iodide (23.5 c.c.), and ether (300 c.c.); after the addition of anisole (200 c.c.), the ether was distilled (bath at 100°). A solution of oxodihydroneostrychnine (28.5 g. of the base, 1 MeOH) in anisole (350 c.c.) was added and the whole heated for 5 hours at 100°. After being poured on ice, the product was extracted by dilute hydrochloric acid and the solution basified with ammonia (dried as a light yellow solid, 27.5 g.). A portion was crystallised from alcohol (charcoal) and from benzene-light petroleum (b. p. 80—100°) and obtained as prismatic needles, which shrank at 130°, m. p. 160° (decomp.) (Found: C, 72.5; H, 7.2. C₂₂H₂₂O₂N₂ requires C, 72.1; H, 7.1%). This base (5 g., crude) was ground with soda-lime (25 g.) and distilled at 400°, and the product from five such batches was worked up in the manner already described. The carbazole fraction had m. p. 116—200°. The infra-red spectrum showed strong bands at 810 cm.⁻¹ (3-methylcarbazole, ca. 10%), the carbazole bands at 845 cm.⁻¹ and 857 cm.⁻¹, and a very weak band at 787 cm.⁻¹ (see above). The absence of 4-methylcarbazole is not established owing to the possible swamping of its relatively weak characteristic bands by stronger neighbouring absorption due to carbazole and 3-methylcarbazole. The low m. p. suggests the presence of 4-methylcarbazole or of some other unidentified constituent.

4-Chloro-*m*-tolylhydrazine.—A hot solution of 4-chloro-*m*-toluidine (5.8 g.) in dilute hydrochloric acid (67 c.c. containing 11 c.c. of concentrated acid) was added to concentrated hydrochloric acid (107 c.c.), cooled to 0°, and diazotised by addition of sodium nitrite (3.2 g.) dissolved in a little water. The diazo-solution was poured into an ice-cold solution of stannous chloride (21 g.) in concentrated hydrochloric acid (26 c.c.). After an hour at 0° the mixture was kept for 12 hours at the room temperature, the solid collected, washed with saturated brine, and triturated with a solution of sodium hydroxide (17 g.) in water (50 c.c.). The base was collected, washed with water, and dried (3.8 g. or 59%). The substance crystallised from water in needles, m. p. 61° (Found: C, 53.5; H, 5.6. C₉H₈N₂Cl requires C, 53.7; H, 5.8%). A mixture of cyclohexanone (2.4 g.), 4-chloro-*m*-tolylhydrazine (3.6 g.), and ethanol (10 c.c.) was refluxed for an hour and added to water. The product was isolated by means of ether (yield, 4.8 g.), and it crystallised from alcohol in plates, m. p. 58°.

The crude cyclohexanone 4-chloro-*m*-tolylhydrazone (from 5.7 g. of chlorotolylhydrazine) was boiled with a mixture of concentrated sulphuric acid (10 c.c.) and water (90 c.c.) for 5 minutes; chloride ion was detected in the aqueous solution. The red oil was extracted with ether leaving a pink solid (0.35 g.) which crystallised from alcohol in dark red needles, m. p. 195—197° (decomp.), and contained nitrogen and chlorine (Found: C, 66.0; H, 4.9; N, 6.1%). The nature of this compound has not been discovered. The oil from the ethereal extract was distilled, b. p. 222—223°/20 mm. (5.7 g.), and treated with light petroleum (b. p. 40—60°). An insoluble white solid residue (0.7 g.) crystallised from aqueous alcohol (charcoal) in white needles, m. p. 199—201° (decomp.) [Found: C, 76.8; H, 7.4; N, 6.9; *M* (Rast in camphor), 220. C₁₃H₁₁ON requires C, 77.6; H, 7.5; N, 7.0%; *M*, 201]. The low percentage of carbon found is due to a trace of chlorine the presence of which was shown by the Beilstein test. This compound

(A) will be further examined. The light petroleum solution was concentrated and afforded 5.0 g. of a pale yellow solid. Recrystallisation from aqueous ethanol gave colourless needles, m. p. 64.5° (Found: C, 70.4; H, 6.5. $C_{13}H_{11}NCl$ requires C, 71.0; H, 6.4%). When the specimens of this 8-chloro-5-methyl-1:2:3:4-tetrahydrocarbazole (I) were examined after a lapse of months, in order to repeat the analysis, it was found that they had decomposed with formation of dark resins.

4-Methylcarbazole (II).—Chloromethyltetrahydrocarbazole (0.5 g.) and palladised charcoal (0.15 g.) were heated (bath at 280–300°) in a stream of hydrogen; evolution of hydrogen chloride ceased after 2 hours.

The mass was extracted with acetone and the methylcarbazole precipitated by addition of water (0.38 g.). The compound crystallised from aqueous ethanol as small white needles, m. p. 115–116° (Found: C, 85.8; H 6.2. $C_{13}H_{11}N$ requires C, 86.1; H, 6.1%). The picrate, m. p. 160.5°, separated from benzene in red needles (Found: C, 56.0; H, 3.6. $C_{13}H_{11}O_7N_4$ requires C, 55.6; H, 3.4%). Other properties of 4-methylcarbazole are mentioned above.

When the compound (A), $C_{13}H_{11}ON$, was similarly dehydrogenated, 0.33 g. gave 0.25 g. of solid material. This crystallised from aqueous ethanol as white needles, m. p. 262° (decomp.) [Found: C, 79.2; H, 5.8; N, 7.2; *M* (Rast in camphor), 195. $C_{13}H_{11}ON$ requires C, 79.2; H, 5.6; N, 7.1%; *M*, 197]. This substance is isomeric with a methylphenoxazine, but phenoxazine has m. p. 156° and 2-methylphenoxazine has m. p. 123–125°, so that it is unlikely to be 3-methylphenoxazine. The only alternative we can suggest is, (IV) whence the tetrahydro-derivative (A) should be (III). The stability of these substances is noteworthy.

1-Chloro-4-methylcarbazole.—Chloromethyltetrahydrocarbazole (1.5 g.) was oxidised by chloranil in xylene according to the method of Barclay and Campbell (*J.*, 1945, 530). The resultant dark oil afforded a picrate (2.1 g.) which crystallised from benzene in dark red needles, m. p. 154.5° (Found: C, 51.7; H, 3.3. $C_{13}H_{11}O_7N_4Cl$ requires C, 51.3; H, 2.9%). The chloromethylcarbazole crystallised from aqueous ethanol in slender, white needles, m. p. 70° (Found: C, 71.6; H, 4.4. $C_{13}H_{11}NCl$ requires C, 72.4; H, 4.7%).

The authors thank the University of Melbourne for a travelling Scholarship and the Carnegie Fund for a grant awarded to one of them (K. H. P.).

They are greatly indebted to Mr. R. E. Richards for his reports on the infra-red absorption spectra.

306. Thermal Decomposition of Explosives in the Solid Phase. Part I. The Thermal Decomposition in a Vacuum of Certain Mono- and Dinitrobenzenediazo-oxides, with a Note on the Kinetics of Thermal Breakdown of 2-Nitrobenzene-4-diazo-1-oxide.

By J. VAUGHAN and L. PHILLIPS.

The rates of decomposition, in a vacuum, of certain nitrobenzenediazo-oxides have been studied between 50° and 120°. Under these conditions mononitrobenzene-2-diazo-1-oxides appear to be less stable than the corresponding 4-diazo-1-oxides. A similar conclusion applies to the dinitrobenzenediazo-oxides. This is probably due to restricted resonance in the 2:1-diazo-oxides owing to proximity of electrostatic charges. Substitution of nitro-groups in positions *o*- or *p*- to the oxygen atom in 2:1-diazo-oxides leads to an increased stability; substitution in the *m*-position appears to be without effect. Similar effects are observed with *o*-substitution on the 4:1-diazo-oxides. These effects can be explained on electronic considerations. The kinetics of thermal decomposition of 2-nitrobenzene-4-diazo-1-oxide have been investigated. The results are in agreement with the theory of solid-phase decomposition put forward by Prout and Tompkins (*Trans. Faraday Soc.*, 1944, 40, 488).

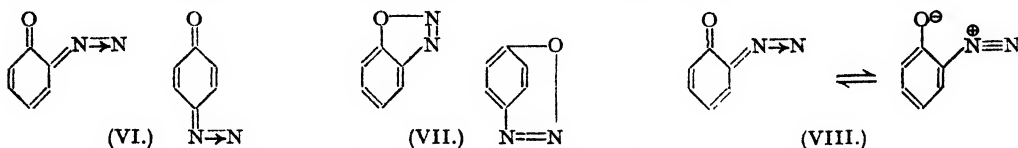

THE following five aromatic diazo-oxides were examined for thermal stability characteristics: 4- (I) and 5-nitrobenzene-2-diazo-1-oxide (II), 2-nitrobenzene-4-diazo-1-oxide (III), 4:6-dinitrobenzene-2-diazo-1-oxide (IV), 2:6-dinitrobenzene-4-diazo-1-oxide (V).

The method used for following the progress of decomposition was essentially that described by Farmer (*J.*, 1920, 117, 1432) in which the compound was allowed to decompose in a vacuum and the course of breakdown followed by means of the gas evolution-time curve. The temperature range covered was 50–120°, and the curves obtained in all cases were sigmoid in shape. Addition of the solid end-products did not result in any acceleration of the breakdown, and the gaseous products were also without catalytic effect. The gaseous products of decomposition of these diazo-oxides consist mainly of nitrogen, nitric and nitrous oxides, and carbon dioxide. Since the nitro-groups of mono- and di-nitrobenzene are comparatively stable at temperatures below 120°, the main process in the thermal decomposition of these diazo-oxides would seem to be fission of the diazo-nitrogen, together with some slight secondary reactions depending on the temperature of decomposition. The failure in all cases to obtain 1 mol. of

nitrogen per mol. of diazo-oxide indicated that some coupling may have occurred with the formation of a relatively stable product.

Of the mononitrobenzene diazo-oxides, the 2-diazo-1-oxides (I) and (II) were considerably less stable thermally than (III), a 4-diazo-1-oxide. This characteristic was also demonstrated by the behaviour of the dinitrobenzene compounds, (V) being more stable than (IV). Results also pointed to the following facts: (a) when a nuclear nitro-group is in an *o*- or *p*-position to the oxygen of the diazo-oxide grouping, a stabilising effect is exerted on the molecule; (b) a nitro-group in the *m*-position appears to be without effect on the stability; (c) the presence of two nitro-groups situated as in (a) leads to a stabilising effect greater than that exerted by only one such group.

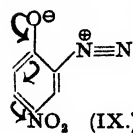

For many years there was considerable doubt as to whether these internal diazo-oxides had a quinonoid structure (VI) or contained an oxide ring (VII). It is, however, now evident that neither of these structures is correct and that the properties of such compounds are best explained on the basis of resonance hybrids, as in (VIII). This argument is reviewed by Hodgson and

Marsden (*J. Soc. Dyers Col.*, 1943, 59, 271), who point out that such a resonating system explains the superior stability of the diazo-oxides over the diazonium compounds. Thus the diazo-oxides are stabilised by their resonance energy, whilst the diazonium salts, not being resonating systems in this sense, are not stabilised in this manner.

Compounds (I), (II), and (III) can therefore be represented structurally by the general formulae shown in (VIII). The resonating energy of such systems is, by definition, greatest (*i.e.*, the greatest degree of stability is obtained) when both hybrids contribute equally to the equilibrium state of the molecule. Now in the "ionised" form of the 2:1-diazo-oxides, the negatively charged oxygen and the positively charged nitrogen are sufficiently close to set up an appreciable electrostatic attraction, so much so that resonance is probably to some extent inhibited. Consequently, the "ionised" form will preponderate, with the result that the resonance energy assumes a comparatively small value.

On the other hand, resonance in the 4:1-diazo-oxides should not be restricted to such an extent because of the greater separation of the electrostatic charges in the ionised form. Consequently, the resonance energy and therefore the stability of the 4:1-diazo-oxides should be greater than that of the corresponding 2:1-diazo-oxides, as has been found to be the case with (I), (II), and (III). Further support for this theory is afforded by the fact that (II) is less stable than (I). Both compounds are 2:1-diazo-oxides, the only difference being that the nitro-group is respectively in the *m*- and the *p*-position. Now, according to the electronic theory of organic

reactions, developed by Ingold *et al.*, the nitro-group is an electron-attracting group which exerts mesomeric effects in aromatic compounds. This effect would be expected to operate to reduce the fractional negative charge on the oxygen atom of the ionised form of (I), as in (IX), thereby decreasing the electrostatic attraction between the ionised groups. The contribution to the equilibrium state made by the non-ionised form therefore increases with consequent increase of resonance energy and therefore stability. Since this mesomeric effect cannot operate from a group in the *m*-position, (II) should be less stable than (I). This relative instability in (II) is enhanced by the fact that the nitro-group in (II) is in the *p*-position to the diazo-group. The electron-attracting nature of the nitro-group will tend therefore to increase the positive nature of the diazo nitrogen and will thus inhibit resonance by favouring the "ionic" structure of the molecule.

Introduction of a second nitro-group into the position ortho to the oxygen (where the mesomeric effect can again operate) should tend further to reduce the fractional charge on the oxygen atom. If the major contribution made to the stable structure before introduction of this second nitro-group still comes from the "ionised" form, this second nitro-group should tend to increase stability by bringing the stable structure nearer to the optimum condition, *i.e.* reducing the "amount" of ionised form. Conversely, it follows that if the introduction of a second nitro-group ortho to the oxygen atom in a mononitrobenzenediazo-oxide results in an increased stability, the "ionised" form must preponderate in the latter structure. Thus the fact that (IV) is more stable than (I) confirms that the "ionised" form of the latter preponderates

in the stable structure. Similarly, the fact that (V) is more stable than (III) indicates that, although (III) is more stable than (I), the ionised form still makes the greater contribution to the

relatively stable (III) structure. The destabilising effect of the adjacent charges in the 2 : 1-diazo-oxides is again illustrated by the fact that (IV) is less stable than the corresponding 4 : 1-diazo-oxide (V).

Kinetics and Mechanism of the Thermal Decomposition.—Investigation of the kinetics and mechanism of the thermal decomposition of nitrobenzenediazo-oxide was not the main object of this work. Attempts at kinetic interpretation have only been made, therefore, where data of sufficient accuracy are available. Furthermore, secondary processes other than elimination of diazo-nitrogen played a large part in the decomposition of dinitrobenzenediazo-oxide, so the kinetics were very complex. Satisfactory data were, however, available for compound (III).

The decomposition of all compounds studied in the present investigation is characterised by sigmoid volume-time curves, and microscopic examination of decomposition products indicates that decomposition probably occurs in the solid phase without the incidence of partial melting which can result in autocatalytic reactions. Considerable work has been carried out by Garner and other investigators during the last 15 years on the kinetics and mechanism of thermal decomposition in the solid phase. The position has been reviewed by Garner (*Trans. Faraday Soc.*, 1938, "Symposium on Solid Phase Reactions"; *Science Progress*, 1938—39, 33, 209), and more recently by Prout and Tompkins (*loc. cit.*), whose treatment of the problem appears to be most complete. Agreement is general that decomposition in the solid phase is initiated at nuclei which are situated mainly at the crystal surface, at lattice imperfections, *i.e.*, where a strain exists, these nuclei being regarded in the widest sense as molecules whose decomposition is highly favoured, *i.e.*, of lower activation energy. The mechanism postulated by Prout and Tompkins (*loc. cit.*), which differs somewhat from that of Garner, is briefly as follows: The surface array of product molecules, which in general have a different unit cell from that of the original substance, sets up strains in the crystal surface which are relieved by formation of cracks (not Smekal cracks, which are produced to relieve strain in the *original* crystals, *i.e.*, they are a property of the crystal itself). At the mouths of these cracks, decomposition will be favoured because of lattice imperfections; reaction therefore spreads down these crevices into the crystal. Covering of the surfaces of these cracks now produces lateral strains which ultimately lead to further cracking from the inner surface. Thus a series of "branchings" will occur and planes of strain will be formed, and along these planes the deformation effect of the product on the electronic structure of an adjacent molecule of unreacted substance will be a maximum and decomposition will be favoured. A chain-like reaction develops, which, however, becomes subject to interference since, when a plane of product molecules is encountered, the chain is broken. By a mathematical consideration of their proposed mechanism Prout and Tompkins derived the relationship

$$\log_{10} p / (p_f - p) = k_1 t + c_1$$

where p is the pressure at a time t , p_f the final pressure, and k_1 and c_1 are constants. This equation should hold from the start of appreciable interference with the branching process (*i.e.*, from the early stages of the reaction) to near the inflexion point of the p - t curve, after which the equation

$$\log_{10} p / (p_f - p) = k_2 t + c_2$$

should hold until the end of the reaction is approached. The graph of $\log p / (p_f - p)$ against t should therefore be two straight lines inclined at an angle to each other. The application of these equations to compound (III) is illustrated in Fig. 3, where $\log v / (v_\infty - v)$ has been plotted against t . The values obtained for k_1 and k_2 at various temperatures are given below:

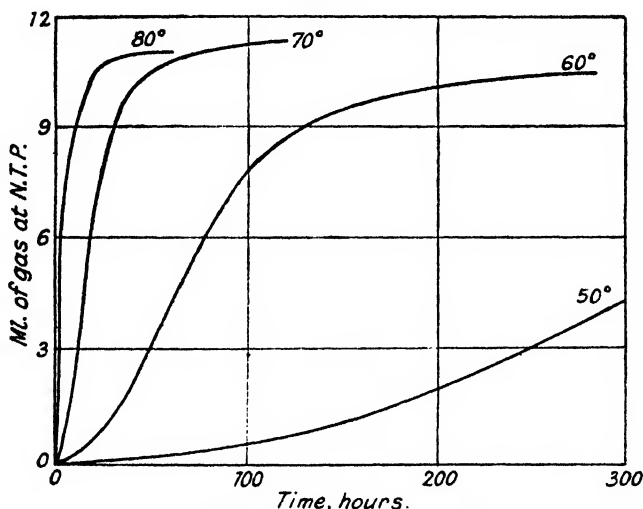

Temp. °	$10^4 k_1$ (sec. ⁻¹), and mean.	$10^4 k_2$ (sec. ⁻¹), and mean.	Temp. °	$10^4 k_1$ (sec. ⁻¹), and mean.	$10^4 k_2$ (sec. ⁻¹), and mean.
90.9°	6.78 } 6.72	8.00 } 8.81	104.4°	38.6 } 39.0	50.1 } 47.7
	6.66 }	8.62 }		39.4 }	45.3 }
95.2	11.0 } 11.3	12.4 } 12.0	110.0	74.5 } 72.6	95.1 } 93.6
	11.6 }	11.6 }		70.6 }	92.1 }
99.1	20.2 } 19.7	22.4 } 21.4			
	19.1 }	20.3 }			

The duplication of values of k_1 is good, but that with k_2 is sometimes not very good, owing probably to the relative inaccuracy of pressure recordings during the final period of reaction. Fig. 4 shows the plot of $\log k_1$ and $\log k_2$ against $1/T$ (where T is the absolute temperature). The slopes of the two lines are almost identical, each giving an activation energy of 35.5 k.-cals. per mol. This indicates that the reactions in both stages are identical, thus supplying further evidence in favour of the theory advanced by Prout and Tompkins. The equations derived by these authors have been used in the interpretation of the volume-time curves obtained from the thermal breakdown of other explosives, and it is hoped to communicate the result of some of this work in the near future.

EXPERIMENTAL.

The method and apparatus used for following the progress of decomposition were essentially those of Farmer (*loc. cit.*). Gas analyses were carried out by a method developed at Bristol University, for details of which we are indebted to Dr. C. E. H. Bawn. This comprises separation of the gases by fractional condensation, followed by analysis of the individual fractions. Fractionation and subsequent analyses were carried out in the absence of air, the gases being pumped off by means of a Toepler pump and measured dry. The main fractions obtained were as follows: Fraction I, gases volatile (in a vacuum) at -186° , comprised O_2 , NO, H_2 , CO, and CH_4 ; Fraction II, gases volatile at -120° , comprised CO_2 and N_2O ; the residue consisted of organic vapours, NO_2 , etc. The individual fractions were analysed by

FIG. 1.

4-Nitrobenzene-2-diazo-1-oxide.

accepted chemical methods. The pure samples of diazo-oxides were prepared and supplied by Dr. T. M. Walters of this Department. They were dried in a vacuum over potassium hydroxide and phosphoric oxide before use. Compounds (I) and (II) were photosensitive and had, therefore, to be dried in the dark. Detailed results obtained were as follows.

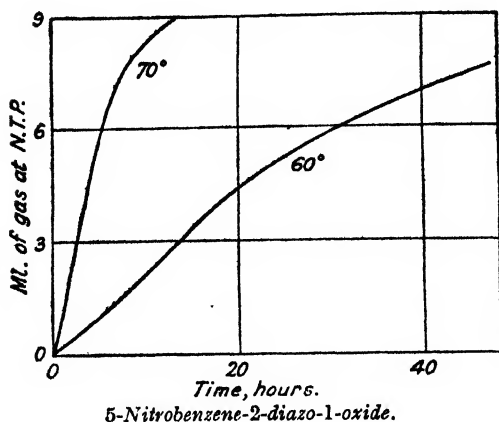

(a) *4-Nitrobenzene-2-diazo-1-oxide* (I).—Thermal decompositions were carried out at 50° , 60° , 70° , and 80° . The gas evolution-time curves were sigmoid in shape (Fig. 1) and decomposition had practically ceased when ca. 0.8 mol. of gas per mol. of (I) had been given off. The gases evolved on complete decomposition at 80° corresponded to 0.84 mol. per mol. of (I) and comprised N_2 , 89.9; NO, 0.7; CO_2 , 8.9; N_2O , 0.5%. It is assumed that the nitrogen is mainly derived from the diazo-group because it is well known that simple aromatic mononitro-compounds are quite stable below ca. 120° . The main reaction involves fission of the diazo-nitrogen, together with a small amount of breakdown of the benzene nucleus. Analysis of the gas at about half-decomposition indicated that the reactions involved are probably the same throughout the decomposition. Decomposition of (I) to which had been added 10% by weight of the reddish-black decomposition residue showed that the end-product is not a catalyst for the reaction and, as would be expected, the volatile products of decomposition were found to be without effect on the characteristics of the breakdown. For decomposition of 0.1 g. at 60° , 70° , and 80° , the times required for evolution of half the final gas volume were approx. 71, 17, and $4\frac{1}{2}$ hrs., respectively. It appears, therefore, that the temperature coefficient of the reaction over this temperature range is 3.5–4 per 10° . Thermal decomposition does not involve complete elimination of diazo-nitrogen; e.g., at 80° only 0.76 mol. (or 1.52 atoms of N) are obtained. The blackish-red colour of the residue and the very intense red colour produced in acetone solution suggest that some coupling had occurred to form a comparatively stable product.

(b) *5-Nitrobenzene-2-diazo-1-oxide* (II).—Typical volume-time curves for thermal breakdown at 60° and 70° are shown in Fig. 2. The rate of thermal decomposition was appreciably greater than that of (I) as is shown by the fact that at 70° the times for evolution of $\frac{1}{2}$ mol. of gas per mol. of (I) or (II) were 20.2 and 6.5 hrs., respectively (0.1 g. tested in each case). The volume-time curve at 60° is sigmoid,

1564 Thermal Decomposition of Explosives in the Solid Phase. Part I.

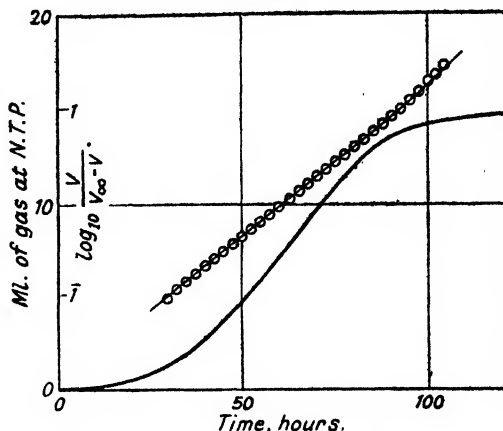

although not as markedly so as with (I), probably owing to the slow decomposition of the latter at this temperature. Complete decomposition at 70° gave 0.77 mol. of gas/mol. of (II), and the composition of

FIG. 2.

5-Nitrobenzene-2-diazo-1-oxide.

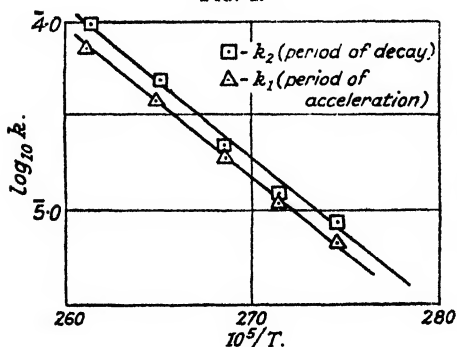

FIG. 3.

2-Nitrobenzene-4-diazo-1-oxide at 99.1°.

this gas was: N_2 , 92.0; CO_2 , 7.1; N_2O , 0.3; NO , 0.6%. After partial decomposition, the composition of the gases evolved was practically the same, indicating that the same main reaction is occurring throughout the decomposition. Of the original diazo-nitrogen only 0.71 mol. (1.42 atoms of N) is eliminated. As with (I), it is probable that some coupling takes place with the formation of a comparatively stable product containing the residual diazo-nitrogen.

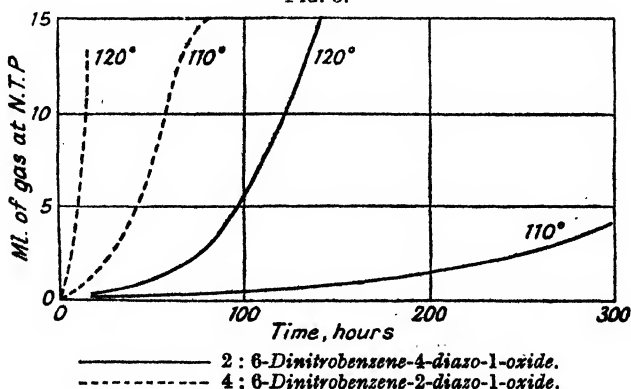

FIG. 4.

(c) 2-Nitrobenzene-4-diazo-1-oxide (III).—Thermal decompositions were conveniently carried out in the range 90—120° and sigmoid volume-time curves were obtained (Fig. 3). On "complete" decomposition at 120°, 1.09 mols. of gas per mol. of (III) were eliminated; the composition of these gases was: N_2 , 90.0; N_2O , 1.0; CO_2 , 7.6; CO , 1.4%, indicating that approximately 0.99 mol. of diazo-nitrogen is eliminated per mol. of (III). From comparison of the time taken to evolve $\frac{1}{2}$ mol. of gas per mol. of (III), a temperature coefficient of 3.5—4 per 10°, for the range 90—110°, was obtained.

(d) 4:6-Dinitrobenzene-2-diazo-1-oxide (IV).—Thermal decompositions were studied in the range 110—120°; typical sigmoid volume-time curves are shown in Fig. 5. The amount of gas evolved on "complete" decomposition is about 1 $\frac{1}{2}$ mol. per mol. of (IV), i.e., far greater than can be accounted for by elimination of the diazo-nitrogen. The composition of the gases was: N_2 , 61.5; NO , 3.0; N_2O , 4.0;

FIG. 5.

CO , 2.5; CO_2 , 28.0%, together with a trace of organic vapours; these results indicate that some breakdown and rearrangement of the benzene nucleus occurs, in addition to loss of diazo-nitrogen.

(e) 2 : 6-Dinitrobenzene-4-diazo-1-oxide (V).—The characteristics of thermal decomposition are similar to those of (IV) and the sigmoid volume-time curves obtained are illustrated in Fig. 5. Compound (V) is, however, considerably more stable than (IV); e.g., 1 mol. of gas is evolved per mol. of (V) in ca. 121 hrs. at 120°, whilst under the same conditions (IV) evolves this amount of gas in 18 hrs. More gas is evolved on "complete" decomposition than can be accounted for by elimination of diazo-nitrogen, and, as with (IV), analysis of this gas indicates that partial breakdown of the benzene nucleus occurs.

The authors wish to express their thanks to the Chief Superintendent, Armament Research, for permission to publish these results.

307. Studies in the Terpenes. Part I. A Synthesis of dl-2 : 2 : 3-Trimethylcyclohexane-1-carboxylic Acid.

By R. N. CHAKRAVARTI.

Manasse and Samuel's keto-acid, obtained by the rearrangement of camphorquinone, was previously reduced by the author to a saturated acid, $C_{10}H_{18}O_2$, the structure of which has now been finally settled by a direct synthesis. It has also been found that methyl 2-methylcyclopentan-1-ol-1-carboxylate leads to a mixture of 2 : 2 : 3-trimethyl- and 2 : 2 : 6-trimethylcyclohexanone by pinacolic change.

In their classical researches on the action of concentrated sulphuric acid on camphorquinone, Manasse and Samuel (*Ber.*, 1897, 30, 3157; 1902, 35, 3831) obtained a dextrorotatory acid, $C_{10}H_{18}O_2$, which was found to have the structure (I) or (II). Of these (II) was preferred as the substance failed to give an isonitroso-compound (Gibson and Simonsen, *J.*, 1925, 127, 1295). Later researches on the action of bromine on the keto-acid, however, revealed that it should be represented as *d*-2 : 2 : 3-trimethylcyclohexan-4-one-1-carboxylic acid (I) (Bhagvat and Simonsen, *J.*, 1927, 77; cf. Bredt-Savelsberg, Zaunbrecher, and Knieke, *Ber.*, 1927, 60, 1801).

The *dl*-modification of this acid was prepared in an analogous manner starting from *dl*-camphorquinone (Chakravarti, *J. Indian Chem. Soc.*, 1943, 20, 301). The first clear evidence for the presence of a ketomethylene grouping in the molecule was supplied by the author (*loc. cit.*) when it was found that the corresponding ethyl ester (as I) readily reacted with ethyl oxalate in presence of sodium ethoxide, leading to the formation of an oxalyl derivative. It was also noted that the inactive keto-acid on reduction with amalgamated zinc and concentrated hydrochloric acid gave an acid, $C_{10}H_{18}O_2$ (Chakravarti, *loc. cit.*; see also *Experientia*, 1947, 3, 27), which, on the basis of formula (I) for the keto-acid, should be represented as *dl*-2 : 2 : 3-trimethylcyclohexane-1-carboxylic acid (III). Additional support for the correctness of structure (III) for the reduced acid was afforded by the dehydrogenation of the corresponding methyl ester with selenium to give a mixture of *o*-xylene and *o*-xylene-3-carboxylic acid.

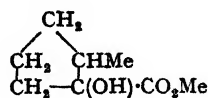

While experiments are in progress for a complete synthesis * of the keto-acid (I), it has now been possible to confirm the structure of the reduced acid as (III) by the following unambiguous synthesis.

Methyl 2-methylcyclopentan-1-ol-1-carboxylate (IV) was allowed to react with excess of methylmagnesium iodide (cf. Meerwein and Unkel, *Annalen*, 376, 152; Chakravarti, *J. Indian*

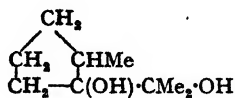

* A partial synthesis of the keto-acid (I) has already been described (Chakravarti, *loc. cit.*). The claim of Guha and Dasgupta (*J. Indian Inst. Sci.*, 1939, 22A, XX, 255) for a complete synthesis of this keto-acid cannot be justified, as the properties of the synthetic acid described by them are wholly inconsistent with those of the *dl*-modification of the acid prepared from *dl*-camphorquinone. The reason is obvious, since, owing to their wrong method of preparation, the product used by them as ethyl α -cyanoglutarate consisted almost wholly (more than 90%) of ethyl γ -cyanopentane- α -cytricarboxylate (cf. Perkin, *J.*, 1904, 85, 417; Ruzicka, Borges de Almeida, and Brack, *Helv. Chim. Acta*, 1934, 17, 183).

For a conversion of santenonequinone into 2 : 3-dimethylcyclohexan-1-one-4-carboxylic acid and a complete synthesis of the latter, see Chakravarti, *J. Indian Chem. Soc.*, 1944, 21, 319, 322.

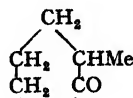

Chem. Soc., 1943, 20, 398) to give the *pinacol* (V). This, on distillation with an aqueous solution of oxalic acid, gave a mixture of the isomeric trimethylcyclohexanones (VI) and (VII) by pinacolic change (cf. Meerwein and Unkel, *loc. cit.*) together with a little non-ketonic product, possibly a mixture of unsaturated hydrocarbons formed by the simple process of dehydration of (V).

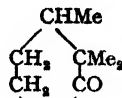

(IV.)

(V.)

(VI.)

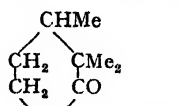

(VII.)

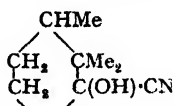

2 : 2 : 3-Trimethylcyclohexanone (VII) had been previously obtained together with 2 : 3 : 6-trimethylcyclohexanone by methylation of 2 : 3-dimethylcyclohexanone with sodamide and methyl iodide (Cornubert and Maurel, *Bull. Soc. chim.*, 1931, 49, 1520). The pure ketone (VII), however, was not obtained, but its presence in the mixture was proved by the isolation of a benzylidene derivative. The inactive modification of the other ketone, 2 : 2 : 6-trimethylcyclohexanone (VI), was isolated from oil of labdanum by Masson (*Compt. rend.*, 1912, 154, 518), who characterised it by the preparation of a semicarbazone, an oxime, and a monobromo-derivative.

In the present instance, the two ketones were separated from the mixture by condensation with ethyl oxalate in presence of sodium ethoxide; according to expectation, only 2 : 2 : 3-trimethylcyclohexanone (VII) furnished an *oxalyl* derivative (VIII). This oxalyl derivative was separated from the neutral matter, and from the latter a semicarbazone was prepared which on hydrolysis with dilute hydrochloric acid gave pure 2 : 2 : 6-trimethylcyclohexanone (VI). This gave an oxime, and in carbon disulphide solution reacted with bromine to give a monobromo-derivative.

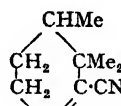

The oxalyl derivative (VIII) on prolonged boiling with concentrated hydrochloric acid gave 2 : 2 : 3-trimethylcyclohexanone (VII) (semicarbazone, benzylidene derivative). (VII) combined almost quantitatively with hydrogen cyanide in presence of a trace of alkali to give a crystalline *cyanohydrin* (IX), which was smoothly dehydrated with excess of phosphorus oxychloride and pyridine to 1-cyano-2 : 2 : 3-trimethylcyclohex-6-ene. This, unlike similar nitriles, was unchanged by prolonged boiling with concentrated hydrochloric acid (cf. Chakravarti, *J. Indian Chem. Soc.*, 1943, 20, 246, 401) or with aqueous or alcoholic potassium hydroxide (cf. Cook and Linstead, *J.*, 1934, 959; King and Robinson, *J.*, 1941, 467), but was hydrolysed by 50% sulphuric acid to 2 : 2 : 3-trimethylcyclohex-6-ene-1-carboxylic acid (XI).

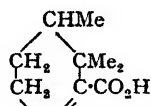

(VIII.)

(IX.)

(X.)

(XI.)

Catalytic hydrogenation of the unsaturated acid (XI) in acetic acid solution in presence of Adams's catalyst gave the desired acid (III) (*p*-phenylphenacyl ester).

EXPERIMENTAL.

2-Methylcyclopentan-1-ol-1-carboxylic acid (as IV) was prepared by the method of Wallach (*Annalen*, 414, 314) with some useful modifications.

The bromination of 2-methylcyclohexanone was carried out under the conditions described by Wallach. After the bromination was complete, however, the acetic acid solution was poured on crushed ice with stirring. The dibromo-ketone separated out as a viscous liquid, which soon solidified. It was filtered off at the pump and washed well with water. The crude product appeared to be rather unstable, as it darkened on keeping, and was always immediately decomposed with alkali in the following way.

The crude dibromo-ketone as obtained from 11.2 g. of 2-methylcyclohexanone was treated with a solution of potassium hydroxide (30 g.) in water (75 c.c.) with shaking, when it readily went into solution with evolution of much heat (some cooling under the tap is necessary as otherwise the product may darken). The solution was gently refluxed on a sand-bath for 45 minutes and then cooled and extracted twice with ether to remove some neutral matter. The alkaline solution was cooled and acidified, when the hydroxy-acid (as IV) separated as a crystalline solid (10.5 g.). The filtrate was saturated with salt and extracted with ether, when a further quantity (about 2 g.) of the acid was obtained. The total yield was directly converted into the methyl ester with methyl alcohol and sulphuric acid. *Methyl*

2-methylcyclopentan-1-ol-1-carboxylate (IV) was obtained as a colourless liquid (12 g.), b. p. 94°/20 mm. (Found : C, 60.4; H, 8.6. $C_8H_{14}O_3$ requires C, 60.7; H, 8.8%).

The Pinacol (V).—A solution of methyl 2-methylcyclopentan-1-ol-1-carboxylate (15.8 g.) in dry ether (25 c.c.) was added dropwise with thorough mixing to an ice-cold solution of methylmagnesium iodide prepared from methyl iodide (26 c.c.) and magnesium (9.6 g.) in ether (75 c.c.). After being kept overnight at the room temperature, the mixture was refluxed on the water-bath for 1½ hours with frequent shaking. The product was well cooled and cautiously decomposed with ice and dilute sulphuric acid. The ethereal layer was separated and the aqueous layer repeatedly extracted with more of the same solvent. The extract was washed with dilute sodium hydroxide solution to remove traces of iodine, and dried (Na_2SO_4). The oily liquid obtained after the removal of ether gave the pinacol (V) as a mobile liquid with a strong camphor-like odour (14 g.), b. p. 110°/19 mm. (Found : C, 68.1; H, 11.5. $C_8H_{16}O_2$ requires C, 68.3; H, 11.4%).

Action of Hot Aqueous Oxalic Acid on the Pinacol (V).—The above product (41 g.) with a 10% aqueous solution of oxalic acid (400 c.c.) was distilled slowly from a flask on a sand-bath. The level of liquid in the flask was kept constant by adding water through a tap funnel as the distillation proceeded. The heating was stopped when there were no more oily drops coming over with the distillate. The total distillate (ca. 500 c.c.) was extracted with ether. The ethereal extract was dried (K_2CO_3) and the solvent was evaporated. The liquid remaining, on distillation, gave a mixture (35 g.), b. p. 170–200°.

This mixture (21 g.) was mixed with ethyl oxalate (22 g.) and added dropwise during 2 hours with shaking to a solution of sodium (3.5 g.) in absolute alcohol (45 c.c.) cooled in a freezing mixture. It was then kept overnight. The product was worked up by adding ice-water and extracting the alkaline solution with ether. From the ethereal solution about 7.5 g. of the neutral unchanged matter (A) were recovered, b. p. 165–190°. The aqueous alkaline solution was acidified with ice-cold dilute sulphuric acid and the separated oil taken up in ether. The extract was washed with water, and then, after evaporation of the solvent, gave the oxalyl derivative (VIII) as an oil (18 g., containing traces of the solvent).

The neutral matter (A) obtained above, after distillation, was heated with semicarbazide acetate in aqueous alcohol. On cooling, the semicarbazone of 2 : 2 : 6-trimethylcyclohexanone separated (3.5 g.). It was obtained pure after two crystallisations from methyl alcohol, m. p. 218° (Masson, *loc. cit.*, gives 220–221°) (Found : C, 61.0; H, 9.6. Calc. for $C_{10}H_{18}ON_3$: C, 60.9; H, 9.6%). The pure semicarbazone on hydrolysis with dilute hydrochloric acid gave pure 2 : 2 : 6-trimethylcyclohexanone (VI) as a volatile liquid with a camphor-like odour, b. p. 180° (Masson, *loc. cit.*, gives b. p. 178–179°) (Found : C, 76.7; H, 11.6. Calc. for $C_8H_{16}O$: C, 77.1; H, 11.4%). It gave an oxime, m. p. 105° (Masson, *loc. cit.*, gives m. p. 106°) (Found : C, 69.6; H, 10.9. Calc. for $C_8H_{17}ON$: C, 69.6; H, 10.9%), and in carbon disulphide solution it reacted with only one mol. of bromine to give a monobromo-derivative, m. p. 41° (Masson, *loc. cit.*, gives m. p. 41°), with evolution of HBr. The monobromo-derivative is very similar to camphor in odour (Found : C, 49.1; H, 6.8; Br, 37.2. Calc. for $C_8H_{15}OBr$: C, 49.3; H, 6.8; Br, 36.5%).

The mother liquor obtained above in the preparation of the semicarbazone gave 3.5 g. of a volatile liquid with a terpene-like smell. This appeared to be a mixture of unsaturated hydrocarbons, but was not further investigated.

Hydrolysis of the Oxalyl Derivative (VIII).—The crude oxalyl derivative obtained above was directly hydrolysed by refluxing it with 20% hydrochloric acid for 48 hours. The liquid was then distilled till the distillate was free from oily drops. The distillate was extracted with ether and the extract dried (K_2CO_3) and fractionated. 2 : 2 : 3-Trimethylcyclohexanone (VII) was obtained as a colourless liquid with camphoraceous odour (9 g.), b. p. 191° (Found : C, 76.8; H, 11.5. $C_8H_{16}O$ requires C, 77.1; H, 11.4%). With semicarbazide acetate in aqueous alcohol it readily gave a semicarbazone crystallising in plates from methyl alcohol, m. p. 214° (mixed m. p. with the semicarbazone of 2 : 2 : 6-trimethylcyclohexanone, 180–185°) (Found : C, 60.9; H, 9.6. $C_{10}H_{18}ON_3$ requires C, 60.9; H, 9.6%). The benzylidene derivative separated from methanol in light yellow needles, m. p. 85° (Found : C, 84.0; H, 8.6. Calc. for $C_{16}H_{20}O$: C, 84.2; H, 8.7%).

1-Cyano-2 : 2 : 3-trimethylcyclohex-6-ene (X).—2 : 2 : 3-Trimethylcyclohexanone (6 g.) was allowed to react with excess of hydrogen cyanide at a low temperature in presence of a drop of potassium cyanide solution. After 10 hours the cyanohydrin was stabilised with a drop of sulphuric acid and the excess of hydrogen cyanide sucked off at the pump, when the product solidified. A small portion of this substance after drying on a porous plate was crystallised from light petroleum, when the pure cyanohydrin (IX) was obtained in colourless needles, m. p. 111°.

The crude cyanohydrin was refluxed for an hour in an oil-bath with excess of phosphorus oxychloride (18 c.c.) and dry pyridine (60 c.c.). It was then cooled and carefully decomposed with ice-water and acidified with hydrochloric acid. By repeated extraction with ether, 1-cyano-2 : 2 : 3-trimethylcyclohex-6-ene (X) was isolated as a colourless liquid (6 g.) with an odour similar to that of phenyl cyanide, b. p. 119°/30 mm. (Found : C, 80.2; H, 9.8. $C_{10}H_{18}N$ requires C, 80.5; H, 10.0%).

2 : 2 : 3-Trimethylcyclohex-6-ene-1-carboxylic Acid (XI).—The unsaturated nitrile obtained above appeared to be particularly resistant to boiling concentrated hydrochloric acid or aqueous or alcoholic potassium hydroxide. It was hydrolysed by gently heating it on a sand-bath for 48 hours with 50% sulphuric acid. In this way a yield of 73% of the unsaturated acid (XI) was obtained. A little neutral matter was also recovered. 2 : 2 : 3-Trimethylcyclohex-6-ene-1-carboxylic acid (XI) crystallised from methyl alcohol in colourless plates, m. p. 135° (Found : C, 71.1; H, 9.4. $C_{10}H_{16}O_2$ requires C, 71.4; H, 9.5%).

2 : 2 : 3-Trimethylcyclohexane-1-carboxylic Acid (III).—The unsaturated acid obtained above was hydrogenated in acetic acid solution in presence of Adams' catalyst. The product had b. p. 110°/3 mm. On being kept in the ice-chest it solidified completely. 2 : 2 : 3-Trimethylcyclohexane-1-carboxylic acid (III) crystallised from methanol, at a low temperature, in shining plates, m. p. 58°, undepressed in admixture with the reduced acid (III) as obtained previously (Found : C, 70.5; H, 10.6. Calc. for $C_{10}H_{18}O_2$: C, 70.6; H, 10.6%).

The *p*-phenylphenacyl ester of the synthetic acid had m. p. 114°, undepressed in admixture with the *p*-phenylphenacyl ester of the reduced acid (III) (Found: C, 79.1; H, 7.6. Calc. for $C_{24}H_{18}O_2$: C, 79.1; H, 7.7%).

My best thanks are due to Prof. J. C. Bardhan for encouragement and to Mr. J. Chakraverti for facilities.

308. *The Preparation and Properties of Triarylstibines.*

By J. I. HARRIS, S. T. BOWDEN, and W. J. JONES.

The influence of nuclear substituents on the reaction of phenylmagnesium halides with antimony trichloride has been examined, and triphenylstibines containing methoxyl, ethoxyl, phenoxyl, chlorine, and bromine as substituents have been prepared. Attempts have also been made to prepare *tri-β-naphthylstibine* through the interaction of *β*-naphthylmagnesium iodide and antimony trichloride. A preliminary examination has been made of the thermal stability of the triphenylstibines.

THE reaction between a substituted phenylmagnesium halide and antimony trichloride has not been studied extensively, and little information is available concerning the influence of nuclear substituents on the properties of triarylstibines. Under ordinary conditions in ethereal solution the reaction between 1 mol. of antimony trichloride and 3 mols. of arylmagnesium halide leads to the formation of the tertiary stibine, $SbAr_3$, and there appears to be no record of the formation of the diarylstibinous chloride, $SbAr_2Cl$, in reactions of this type. In the present investigation, however, it was found that *di-o-anisylstibinous chloride* and *tri-o-anisylstibine* were produced when the antimony halide and *o*-anisylmagnesium bromide reacted in ethereal solution at 40°. It is noteworthy that Makin and Waters (*J.*, 1938, 843) found that triarylstibine dichlorides, $SbAr_3Cl_2$, triarylstibines, and diarylstibinous chlorides were generally produced when diazonium chlorides reacted with antimony under acetone. From bases containing *o*-substituents, only traces of quinquivalent antimony compounds were formed, the main products being the triarylstibines accompanied by a smaller quantity of the diarylstibinous chloride, and it was suggested that the non-formation of quinquivalent antimony compounds may be due to steric hindrance. In the Grignard synthesis, however, there is no possibility of the formation of triarylstibine dichloride, and though the conversion of *di-o-anisylstibinous chloride* into the tertiary stibine may be affected to some extent by steric hindrance, it is evident that this is a subsidiary factor in view of the fact that *o*-phenetylmagnesium bromide reacts with antimony trichloride to give a relatively high yield of *tri-o-phenetylstibine*.

Previous workers have experienced some difficulty in preparing *m*-substituted triphenylstibines by the Grignard synthesis. Thus Challenger and Pritchard (*J.*, 1924, 125, 869) were able to isolate only *tri-m-tolylstibine hydroxychloride* in an attempted preparation of *tri-m-tolylstibine*, and Goddard (*J.*, 1923, 123, 2319) found that the Grignard method gave a low yield of *tri-m-xylylstibine* although the compound may be obtained in high yield by the action of sodium on 4-bromo-*m*-xylene and antimony trichloride. In the present work, it was found that *m*-anisylmagnesium iodide reacted smoothly with antimony trichloride to form *tri-m-anisylstibine* in good yield. The fact that *tri-p-phenoxyphenylstibine* was obtained in fair yield by the Grignard synthesis shows that a phenoxy group does not interfere appreciably with the normal formation of a tertiary stibine.

A chlorine atom in the *p*-position was found to have little effect on the course of the reaction, and the yield of *tri-p-chlorophenylstibine* was good. O'Donnell (*Iowa State Coll. J. Sci.*, 1945, 20, 34) has reported that *tri-p-bromophenylstibine* prepared by the Grignard method is obtained as an oil which can only be converted into crystals, m. p. 134–135°, by inoculation with a specimen of the stibine prepared by reduction of the stibine dichloride, m. p. 184–185°. In the present investigation *tri-p-bromophenylstibine* was obtained as an oil from which a small amount of the crystalline stibine, m. p. 108–109°, was isolated. This material in alcoholic solution gave on treatment with cupric chloride the stibine dichloride, m. p. 200–201°, which agrees with the value given by Makin and Waters (*loc. cit.*), who prepared the dichloride from the diazonium salt and metallic antimony.

The only information given in the literature concerning the thermal stability of triarylstibines is that triphenylstibine undergoes some decomposition when distilled under ordinary pressure (Michaelis and Reese, *Annalen*, 1886, 233, 48) and that *tri-p-diphenylstibine* decom-

poses at the boiling point with formation of antimony, diphenyl, and other products (Worrall, *J. Amer. Chem. Soc.*, 1930, 52, 2048). A survey has therefore been made of the behaviour of triarylstibines at high temperature in nitrogen and in oxygen. When triphenylstibine is kept at 320° in nitrogen for 3 hours it decomposes into benzene, diphenyl (10%), free antimony (17%), and a non-crystallisable antimony compound. The formation of the hydrocarbons arises through the rupture of the Sb-C linkage and the subsequent hydrogenation and dimerisation of the free phenyl radicals to form benzene and diphenyl, respectively. The disproportionation of the radical SbPh_2 , the dimeric form of which has been prepared by Blicke (*J. Amer. Chem. Soc.*, 1931, 53, 1025), is doubtless responsible for the liberation of free antimony and the formation of the complex antimony compound. When triphenylstibine is heated in a sealed tube at 360° for 3 hours, only 9% of the antimony appears in the free state and the amount of diphenyl formed is small. The decomposition is thus facilitated by removal of the more volatile products from the reaction system.

An indication of the thermal stability of a triarylstibine may be obtained by observing the temperature at which the melt becomes turbid when heated in nitrogen. The different influence of *o*-methoxyl and *m*-methoxyl is reflected in the low and the high decomposition temperature, respectively, of tri-*o*- and tri-*m*-anisylstibine as compared with that of triphenylstibine. Tri-*o*-phenetylstibine also has a relatively low decomposition temperature. Nuclear chlorine or bromine does not greatly affect the decomposition temperature but the rate of decomposition is materially reduced. The decomposition temperatures of the triarylstibines in oxygen do not differ appreciably from those in nitrogen, but the rate of reaction is much higher. The behaviour towards oxygen, which is so markedly different from that of the trialkylstibines, shows that the tendency of the antimony atom to increase its 3-covalency is greatly reduced by the presence of aryl groups.

The triarylstibines form dihalides, SbAr_3X_2 , in which the halogen atoms are probably attached to the antimony atom by resonance linkages of the type known to occur in the trialkylstibine dihalides (Wells, *Z. Krist.*, 1938, 99, 367). All the dichlorides and dibromides, except the tri-*o*-phenetyl derivatives, melt without appreciable decomposition. The majority of the alkyloxy- and halogeno-substituted triphenylstibine di-iodides not only melt with decomposition but darken below the melting point.

Tri-o-chlorophenylstibine, tri-*p*-chlorophenylstibine, and tri-*p*-bromophenylstibine are similar to triphenylstibine inasmuch as they do not form a stable addition compound with mercuric chloride at ordinary temperature. It appears that such a compound is formed as an unstable intermediate which undergoes disproportionation into the arylmercuric chloride, HgArCl , and antimony trichloride. The inhibitory influence of alkyloxy- and methyl substituents upon this reaction is much greater than that of halogen substituents.

EXPERIMENTAL.

Tri-o-anisylstibine.—A filtered solution of *o*-anisylmagnesium bromide (1 mol.) was treated with an ethereal solution of antimony trichloride (0.25 mol.). After being boiled for an hour, the mixture was poured into ice-water, and the whole filtered. The residue was extracted first with warm ether (this extract being reserved for later treatment) and then with benzene. The *stibine* was deposited on concentrating the benzene solution; lustrous plates, m. p. 189°, from benzene-chloroform (Found: C, 56.2; H, 5.0; Sb, 27.5. $\text{C}_{11}\text{H}_{11}\text{O}_3\text{Sb}$ requires C, 56.9; H, 4.8; Sb, 27.5%).

Di-o-anisylstibinous Chloride.—The ethereal extract from the above preparation was concentrated, and the deposited *chloride*, after several crystallisations from benzene-alcohol, was obtained in plates, m. p. 116–117° (Found: Cl, 9.3; Sb, 32.4. $\text{C}_{10}\text{H}_{10}\text{O}_2\text{ClSb}$ requires Cl, 9.8; Sb, 32.8%).

Tri-m-anisylstibine.—*m*-Anisylmagnesium iodide was treated with antimony trichloride as described above. After treatment with ice-water, the ethereal solution was evaporated and the residual oil was subjected to steam-distillation to remove volatile material. From an alcoholic solution of the oil, the *stibine* separated in plates; yield 50%. The pure *stibine* had m. p. 88.5–89.0° (Found: C, 56.8; H, 5.0; Sb, 27.2. $\text{C}_{11}\text{H}_{11}\text{O}_3\text{Sb}$ requires C, 56.9; H, 4.8; Sb, 27.5%).

Tri-o-phenetylstibine.—Prepared from *o*-phenetylmagnesium bromide and antimony trichloride, the *stibine* was obtained in 56% yield; needles, m. p. 123.5–123.8°, from alcohol (Found: C, 59.7; H, 5.6; Sb, 25.2. $\text{C}_{14}\text{H}_{17}\text{O}_3\text{Sb}$ requires C, 59.4; H, 5.6; Sb, 25.1%).

Tri-p-phenoxyphenylstibine.—*p*-Phenoxyphenylmagnesium bromide was prepared by refluxing for 24 hours *p*-bromodiphenyl ether, ether, and magnesium powder which had been activated *in situ* by strong heating with iodine. To favour completion of the reaction, benzene was added in the latter stages. The filtered solution was treated with antimony trichloride as previously described. The *stibine* was obtained as a white solid, m. p. 157°, after repeated crystallisation from alcohol (Found: C, 69.1; H, 4.5; Sb, 19.4. $\text{C}_{18}\text{H}_{19}\text{O}_3\text{Sb}$ requires C, 68.7; H, 4.3; Sb, 19.4%).

Tri-o-chlorophenylstibine.—The *stibine* was prepared from *o*-chlorophenylmagnesium bromide and antimony trichloride, but the yield was very low. After repeated crystallisation from glacial acetic acid and then from alcohol-benzene, the compound was obtained in white feathery crystals, m. p. 136–137° (Found: Cl, 23.1; Sb, 26.4. $\text{C}_{10}\text{H}_9\text{Cl}_2\text{Sb}$ requires Cl, 23.3; Sb, 26.7%). The *stibine* did not reduce

cupric chloride in alcoholic solution at room temperature, but it reacted with bromine and iodine. The stibine did not form a stable mercurichloride.

Tri-*p*-chlorophenylstibine.—No appreciable amount of dimagnesium derivative was produced in the reaction of *p*-chlorobromobenzene with magnesium (cf. Bodroux, *Compt. rend.*, 1903, 136, 1138). Treatment of *p*-chlorophenylmagnesium bromide with antimony trichloride gave the stibine; feathery crystals, m. p. 99.5–100.5°, from alcohol–benzene (Found: C, 47.3; H, 2.5; Cl, 23.5; Sb, 26.9. $C_{18}H_{15}Cl_3Sb$ requires C, 47.4; H, 2.7; Cl, 23.3; Sb, 26.7%).

Tri-*p*-bromophenylstibine.—Interaction of *p*-bromophenylmagnesium bromide and antimony trichloride gave a low yield of the stibine; glistening crystals, m. p. 109.8–110.4°, from alcohol–benzene (Found: Br, 40.5; Sb, 20.4. Calc. for $C_{18}H_{15}Br_3Sb$: Br, 40.6; Sb, 20.6%). The pure stibine was very soluble in benzene, ether, and chloroform, but only slightly soluble in light petroleum. It reacted with mercuric chloride in alcoholic solution to form a white precipitate which could not be recrystallised from the usual solvents.

Tri- β -naphthylstibine.— β -Iodonaphthalene (Schmidlin and Huber, *Ber.*, 1910, 43, 2829) was converted into the magnesium derivative, which was treated with antimony trichloride in accordance with the usual procedure. After the solution had been boiled for an hour and then treated with ice-water, the mixture was filtered. The solid was repeatedly extracted with hot benzene, and after removal of the solvent, the residual oil was triturated with ligroin until it solidified. Repeated crystallisation of the material from acetone gave the stibine as a yellow solid which partly melted at 195° (Found: C, 69.3; H, 4.9; Sb, 23.3. $C_{30}H_{21}Sb$ requires C, 71.6; H, 4.2; Sb, 24.2%). The yield was very low and the stibine could not be further purified owing to its slight solubility in the usual organic solvents. It did not form an addition compound with mercuric chloride and did not reduce cupric chloride, but it reacted with light petroleum solutions of bromine and iodine.

Addition Compounds.—The addition compounds listed in the table were prepared by treating the triarylstibine with solutions of cupric chloride, bromine, iodine, or mercuric chloride. Inasmuch as the majority of the di-iodides are susceptible to hydrolysis by traces of moisture, all reagents used in their preparation were thoroughly dried before use.

Thermal Stability of Triarylstibines.—The temperature of the stibine was raised at a rate of 3–4°/min. by heating the material in a stream of nitrogen or oxygen in a small vessel provided with a side-tube in communication with U-tubes for the condensation of volatile products. The temperature at which turbidity first appeared in the molten stibine was taken as the decomposition temperature; those in nitrogen and oxygen, respectively, were as follows: triphenylstibine, 250°, 265°; tri-*o*-anisylstibine, 200°, 200°; tri-*m*-anisylstibine, 258°, 260°; tri-*o*-phenetylstibine, 200°, 205°; tri-*o*-chlorophenylstibine, 260°, —; tri-*p*-chlorophenylstibine, 230°, 265°; tri-*p*-bromophenylstibine, 262°, 250°; tri-*p*-phenoxyphenylstibine, 265°, 260°. Although there was generally little difference between the decomposition temperatures in nitrogen and in oxygen, the rate of reaction was invariably higher in the latter.

Triphenylstibine (1 g.), maintained at 325° for 3 hours under nitrogen in the above apparatus, gave a

small amount of benzene, and diphenyl (0.1 g.). The grey residue in the pyrolysis vessel consisted of a viscous oil and a finely-divided solid. After being washed with acetone, the solid (0.17 g.) was shown to be free antimony (Found : Sb, 99.4%). The acetone solution of the oil gave a positive test for antimony, but no solid product could be isolated.

Triphenylstibine (10 g.) was maintained at 360° in a sealed tube for 3 hours. On cooling, the tube was found to be free from excess pressure, and the pyrolysis product consisted of free antimony (0.3 g. Found : Sb, 99.3%) and a pale green viscous liquid. The latter on fractionation gave triphenylstibine (8.4 g.) and a residue which could not be crystallised. In a repetition of the experiment, the pyrolysis product was subjected to steam-distillation, but the amount of diphenyl isolated was small.

309. *The Synthesis of α -Amino- γ -(*p*-hydroxyphenyl)butyric Acid, a Homologue of Tyrosine.*

By W. CHARLES EVANS and NORMAN WALKER.

Because of the known intermediate formation of indole derivatives in the *in vitro* production of melanin from tyrosine under the influence of tyrosinase, it became of interest to study the action of this enzyme on the next higher homologue of tyrosine. By this means it seemed possible that data relating to the analogous formation of quinoline compounds by enzyme action might be obtained.

α -Amino- γ -(*p*-hydroxyphenyl)butyric acid has been synthesised by two different routes, and some related intermediate compounds are described.

THE elucidation of the series of chemical reactions involved in the formation of melanin from tyrosine under the influence of the enzyme tyrosinase has been the subject of several investigations (see Raper *et al.*, *Physiol. Rev.*, 1928, 8, 245; Evans and Raper, *Biochem. J.*, 1937, 31, 2162; Clemo and Weiss, *J.*, 1945, 702). In the presence of tyrosinase, a number of compounds structurally related to tyrosine, and possessing great physiological interest (*e.g.*, adrenaline, epinine, tyramine, etc.) are oxidised and give rise, where the side-chain configuration allows, to indole compounds, the formation of which has been established in most cases (Dulière and Raper, *Biochem. J.*, 1930, 24, 259). It is generally assumed that the *o*-quinone of 3 : 4-dihydroxyphenylalanine undergoes ring closure spontaneously, without mediation of the enzyme. With esters of tyrosine, however, and compounds where the amino-group is fully alkylated, including quaternary ammonium salts, ring closure does not take place after quinone formation, although additional oxygen is utilised, the subsequent course of the reaction being unknown. It is clear from the work of Bloch and Schaaf (*Biochem. Z.*, 1926, 162, 181) and of Heard and Raper (*Biochem. J.*, 1933, 27, 36) that under changed conditions of pH and temperature, side reactions occur to a greater or less extent, a fact which the latter authors deem important in relation to the biochemical origin of adrenaline from tyrosine or some similar precursor.

α -Amino- γ -(*p*-hydroxyphenyl)butyric acid has been synthesised in order to study the action of tyrosinase on it, with particular reference to the fate of the side chain. If the reaction follows an analogous course to the tyrosine-tyrosinase system, the eventual formation of quinoline derivatives would be expected.

Attempts to effect the condensation of *p*-methoxyphenylacetaldehyde with hippuric acid, acetylglycine, or hydantoin failed to yield the anticipated derivatives of α -amino- γ -(*p*-methoxyphenyl)butyric acid, in spite of a large variety of experimental conditions.

Two alternative methods for the synthesis of α -amino- γ -(*p*-hydroxyphenyl)butyric acid were employed : (a) β -(*p*-Methoxyphenyl)propionitrile, prepared from anisaldehyde, was reduced by stannous chloride under the usual conditions of the Stephen reaction to yield *p*-methoxyphenylpropaldehyde, which, when condensed with ammonium cyanide, followed by hydrolysis of the resulting aminocyanohydrin, afforded α -amino- γ -(*p*-methoxyphenyl)butyric acid. The latter compound was demethylated by treatment with hydriodic acid and red phosphorus in the usual manner to yield the desired amino-acid.

(b) 2-(*p*-Aminophenyl)ethyl bromide, obtained by reducing the corresponding nitro-compound, was converted into 2-(*p*-hydroxyphenyl)ethyl bromide by diazotisation of the amino-group followed by hydrolysis of the diazonium compound in the usual manner. The hydroxy-compound was condensed with the sodio-derivative of benzamidomalonic ester in anhydrous ethanol (*cf.* Redemann and Dunn, *J. Biol. Chem.*, 1939, 130, 341), and hydrolysis of the condensation product with aqueous hydrobromic acid gave the desired α -amino- γ -(*p*-hydroxyphenyl)butyric acid. The results of the investigation on the action of tyrosinase on this amino-acid will be reported later.

1572 *Synthesis of α -Amino- γ -(*p*-hydroxyphenyl)butyric Acid, etc.*

EXPERIMENTAL.

(All m. ps. are uncorrected.)

p-Methoxyphenylpropionitrile (cf. Goldschmidt and Fraenkel, *Monatsh.*, 1914, **35**, 283).—*p*-Methoxyphenylpropionamide (6 g.), obtained by the method of Barger and Walpole (*J.*, 1909, **95**, 1724), dissolved in dry xylene, was boiled vigorously whilst phosphoric oxide (12 g.) was added in small portions with shaking. The mixture was boiled under reflux for 15 minutes, the reaction liquid filtered, and the xylene removed by distillation under reduced pressure on the water-bath. The residue was distilled under reduced pressure, and the fraction, b. p. 160–165/13 mm. (3 g., yield 50%), was collected. It was a colourless oil possessing a characteristic smell.

p-Methoxyphenylpropaldehyde.—Finely powdered anhydrous stannous chloride (10 g., 1.5 mols.) was suspended in dry ether (25 c.c.), cooled in ice and saturated with dry hydrogen chloride, until a homogeneous solution was obtained. *p*-Methoxyphenylpropionitrile (5 g., 1 mol.) was then added, the reaction mixture shaken vigorously, and the stoppered reaction vessel set aside at room temperature overnight. The white, crystalline aldimino-stannichloride which separated was collected on a dry filter, and washed with dry ether. It was hydrolysed to the aldehyde by suspension in warm water made definitely alkaline with aqueous sodium carbonate, followed by extraction with ether. The ethereal solution was dried (Na_2SO_4), and the solvent removed. The oily residue was distilled under reduced pressure, giving *p*-methoxyphenylpropaldehyde, b. p. 130–135°/15 mm. (4.8 g., 90%). On condensation with semicarbazide hydrochloride in the usual way, it gave a *semicarbazone*, which on crystallisation from benzene afforded white needles, m. p. 140–142° (Found: C, 59.2; H, 7.0; N, 18.7. $\text{C}_{11}\text{H}_{11}\text{O}_2\text{N}_2$ requires C, 59.1; H, 6.8; N, 19.0%). This aldehyde could also be obtained, in poor yield, by distillation under reduced pressure of an intimate mixture of the barium salt of *p*-methoxyphenylpropionic acid with barium formate and silver sand.

*α -Amino- γ -(*p*-methoxyphenyl)butyric Acid.*—A modification of Strecker's synthesis due to Lapworth and Cocker (*J.*, 1931, 1371) was employed. *p*-Methoxyphenylpropaldehyde (4.5 g., 1 mol.) was added gradually, with stirring, to a well-cooled solution of ammonia (0.9 g., *d* 0.88, 2 mols.) and hydrogen cyanide (1.4 g., 2 mols.). The reaction mixture was shaken mechanically at room temperature for several hours, and left for 2 days to attain equilibrium. To the mixture, which had now darkened appreciably, was slowly added excess of sulphuric acid (40% w/v; 5–7 mols.). Hydrolysis was effected by heating for 3 hours at 125° until a test portion of the solution gave no reaction for ferrocyanide with excess of sodium hydroxide and ferrous hydroxide. The solution was diluted with several times its volume of water, and powdered barium carbonate (A.R.) was gradually added until the mixture was definitely alkaline to litmus. Steam was passed through the boiling solution until all the ammonia had been driven off. The bulky precipitate of barium sulphate was filtered off, and well washed with boiling, very dilute aqueous sulphuric acid. The combined filtrates were treated with powdered lead carbonate until effervescence ceased, and the solution no longer showed an acid reaction to Congo-red, the mixture filtered, and the residue of lead sulphate washed with water. The combined filtrate and washings were saturated with hydrogen sulphide, the lead sulphide removed, and the filtrate concentrated to a small bulk (50 c.c.). The concentrate was decolorised (norite) and filtered, and on further concentration and cooling, a white crystalline solid separated. After recrystallisation from aqueous alcohol the *amino-acid* formed needles (2 g., 35%), m. p. 245–246° (Found, C, 63.1; H, 6.9; N, 6.75. $\text{C}_{11}\text{H}_{11}\text{O}_3\text{N}$ requires C, 63.2; H, 7.1; N, 6.7%).

*α -Amino- γ -(*p*-hydroxyphenyl)butyric Acid.*—The above methoxy-acid was demethylated by the method of Harington and McCartney (*Biochem. J.*, 1927, **21**, 852), the acid (5 g.), red phosphorus (5 g.), hydriodic acid (25 c.c., *d* 1.7), and acetic anhydride (25 c.c.) being boiled together under reflux for 1.5 hours. The reaction mixture was filtered through asbestos-wool, the phosphorus well washed with glacial acetic acid, and the filtrate evaporated to dryness in a vacuum. Water was then added, and the evaporation repeated. The residue was taken up in a little water, and sufficient lead carbonate added just to neutralise the trace of acid present and to remove the iodine. The precipitate was filtered off and washed thoroughly with distilled water, the filtrate saturated with hydrogen sulphide, the lead sulphide removed, and the clear filtrate decolorised (norite) and concentrated to small bulk. On cooling, crystals soon developed, which were collected and recrystallised twice from boiling water, whence a white micro-crystalline powder was obtained (1.5 g.) m. p. 265° (Found, C, 61.5; H, 6.7; N, 7.2. $\text{C}_{10}\text{H}_9\text{O}_3\text{N}$ requires, C, 61.5; H, 6.66; N, 7.18%). The *amino-acid* on treatment with a solution of diazotised *o*-chloroaniline gave a red azo-compound. Nitrogen was evolved on treatment with cold nitrous acid.

p-(2-Bromoethyl)aniline Hydrochloride.—2-(*p*-Nitrophenyl)ethyl bromide (10 g.), prepared from 2-phenylethyl alcohol by the method of Foreman and McElvain (*J. Amer. Chem. Soc.*, 1940, **62**, 1436), was added in 1 g. portions to a solution of stannous chloride (40 g.) in concentrated hydrochloric acid (100 c.c.) which was heated on the steam-bath, the liquid being shaken vigorously after each addition; the solid nitro-compound melted to an oil, which gradually reacted, and dissolved on shaking, a further portion being then added. When the addition was completed, the mixture was heated on the steam-bath for a further 45 minutes. The reaction mixture was then freed from a little oil by extraction with hot benzene, and the aqueous layer was separated, and cooled in a freezing mixture. An excess of aqueous sodium hydroxide was added, with careful cooling until all the tin, which was at first precipitated as hydroxide, had dissolved. The alkaline solution was thrice extracted with ether, the combined extract washed with water, and the amine was removed from the ether by shaking with 3.5*N*-hydrochloric acid (22 c.c.). After separation of the aqueous layer, *p*-(2-bromoethyl)aniline hydrochloride (7.75 g.) crystallised out; it recrystallised from water in nearly colourless needles, m. p. 211° (decomp.).

p-(2-Bromoethyl)phenol.—The foregoing hydrochloride (10 g.) was dissolved in water (100 c.c.) and 30% sulphuric acid (20 c.c.), the mixture warmed to 55°, and a solution of sodium nitrite (3.5 g.) in water (20 c.c.) was added slowly, with mechanical stirring. A dark reddish-brown oil possessing a sharp sickly smell separated, and the mixture was heated on the steam-bath for a further 15 minutes, then cooled;

the oil was extracted with ether, the extract dried (Na_2SO_4), the solvent removed, and the residual oil distilled, yielding *p*-(2-bromethyl)phenol (2.3 g.) as a viscous yellow oil, b. p. 150–155°/12 mm.

*α -Amino- γ -(*p*-hydroxyphenyl)butyric Acid*.—Benzamidomalonate ester (2.8 g.), prepared as described by Redemann and Dunn (*J. Biol. Chem.*, 1939, 130, 341) but with Painter's modification (*J. Amer. Chem. Soc.*, 1940, 62, 232), was added to a hot solution of sodium (0.25 g.) in absolute alcohol (50 c.c.), and when the solid sodio-derivatives had separated *p*-(2-bromoethyl)phenol (2.3 g.) was added, and the mixture heated under reflux for 3 hours. The bulk of the alcohol was removed by distillation, and the residue diluted with water (100 c.c.) and extracted with ether. The extract was dried (Na_2SO_4), and the solvent removed, leaving ethyl 2-(*p*-hydroxyphenyl)ethylbenzamidomalonate as a brown oil (3 g.). This was hydrolysed by refluxing with 48% aqueous hydrobromic acid (20 c.c.) for 10 hours. The mixture was diluted with boiling water (40 c.c.), filtered, and left in the ice-chest overnight. Benzoic acid separated, and was filtered off, the filtrate being evaporated to dryness in a vacuum. The residual solid was extracted with water (15 c.c.), the extract boiled (norite), filtered, and the filtrate carefully neutralised with aqueous ammonia and kept in the ice chest for 24 hours. *α -Amino- γ -(*p*-hydroxyphenyl)butyric acid* (0.17 g.), m. p. 265° (decomp.), separated as a microcrystalline powder; recrystallised from 50% aqueous alcohol, it had m. p. 265° (decomp.) undepressed on admixture with the amino-acid synthesised by the previous route (Found: C, 60.3; H, 6.52; N, 7.2%).

BIOCHEMISTRY SECTION, DEPT. OF ANIMAL HEALTH,
UNIVERSITY COLLEGE, ABERYSTWYTH.

[Received, January 30th, 1947.]

310. Some 1:1'- and 2:2'-Dinaphthyl Derivatives and a New Synthesis of 3:3'-Dinitro-1:1'-dinaphthyl.

By HERBERT H. HODGSON and JOHN HABESHAU.

3:3'-Dinitro-1:1'-dinaphthyl, formerly prepared by the action of copper on 1-iodo-3-nitronaphthalene, is now synthesised from naphthidine.

4:4'-DIACETAMIDO-1:1'-DINAPHTHYL readily dinitrated to give 3:3'-dinitro-4:4'-diacetamido-1:1'-dinaphthyl which was hydrolysed by boiling ethyl-alcoholic sulphuric acid to 3:3'-dinitro-4:4'-diamino-1:1'-dinaphthyl, a compound easily bisdiazotised by a nitrosyl-glacial acetic acid procedure (cf. Hodgson and Walker, *J.*, 1933, 1620; Schoutissen, *J. Amer. Chem. Soc.*, 1933, 55, 4535). Replacement of both diazo-groups by hydrogen was effected by means of ethanol to give 3:3'-dinitro-1:1'-dinaphthyl in over 80% yield, a compound previously prepared in poor yield by the action of copper on 1-iodo-3-nitronaphthalene (cf. Cumming and Howie, *J.*, 1931, 3179; Chudožilov, *Chem. Listy*, 1925, 19, 187). Reduction to 3:3'-diamino-1:1'-dinaphthyl by the procedure of Cumming and Howie (*loc. cit.*) was confirmed, and so the 3:3'-positions taken up by the nitro-groups in the original nitration of 4:4'-diacetamido-1:1'-dinaphthyl were established. Replacement of the amino- by hydroxyl groups in 3:3'-dinitro-3:3'-diamino- or 3:3'-diacetamido-1:1'-dinaphthyl to give 3:3'-dinitro-4:4'-dihydroxy-1:1'-dinaphthyl was effected by boiling aqueous sodium hydroxide, and the disodium salt of this compound was sparingly soluble in cold water.

1:1'-DIACETAMIDO-2:2'-DINAPHTHYL is dinitrated in the 4:4'-positions to give 4:4'-dinitro-1:1'-diacetamido-2:2'-dinaphthyl, as proved by hydrolysis with ethanol and concentrated sulphuric acid to give the known 3:6-dinitro-1:2:7:8-dibenzocarbazole (Hodgson and Habeshaw, this vol., p. 77).

EXPERIMENTAL.

Nitration of 4:4'-Diacetamido-1:1'-dinaphthyl.—The diacetyl compound (1.9 g.), prepared by the addition of acetic anhydride to a boiling solution of naphthidine in glacial acetic acid (cf. Cumming and Howie, *J.*, 1932, 528), was added gradually in a finely divided state with stirring to nitric acid (35 c.c., *d* 1.42), the temperature being maintained below 15°; the solution darkened as the solid dissolved and, after about 15 minutes, a yellow precipitate of 3:3'-dinitro-4:4'-diacetamido-1:1'-dinaphthyl began to separate. After being stirred for 30 minutes from the final addition of the acetyl compound, the mixture was poured into water, the yellow precipitate (1.95 g., m. p. 332–335°) filtered off, washed acid free with water, dried, and crystallised first from nitrobenzene in which it was moderately soluble and then from glacial acetic acid in which it was sparingly soluble, to give yellow micro-crystals, m. p. 342–343° (Found: N, 12.5. $\text{C}_{20}\text{H}_{14}\text{O}_4\text{N}_4$ requires N, 12.2%).

3:3'-Dinitro-4:4'-diamino-1:1'-dinaphthyl.—This was obtained by refluxing the diacetyl derivative above (5 g.) for 10 hours with ethanol (50 c.c.) and dilute sulphuric acid (50 c.c., *d* 1.08); the solution deepened in colour and on being poured into water (600 c.c.) afforded the free amine (4.5 g.) which was filtered off, washed with water until acid-free and then with ethyl acetate, and crystallised once from nitrobenzene in which it was readily soluble at the boil and twice from glacial acetic acid in which it was moderately soluble, to give bright yellow micro-plates, m. p. 338–339° (Found: N, 14.8. $\text{C}_{20}\text{H}_{14}\text{O}_2\text{N}_4$ requires N, 15.0%).

3:3'-Dinitro-1:1'-dinaphthyl.—This was prepared by addition of finely powdered 3:3'-dinitro-

4 : 4'-diamino-1 : 1'-dinaphthyl (5.7 g.) to a mixture of sodium nitrite (7 g.) in sulphuric acid (60 c.c., *d* 1.84) below 40°; a deep green solution was formed which was diluted with glacial acetic acid at such a rate that the temperature was kept between 45° and 50°, and the colour became golden-brown. After being stirred for 1 hour, the mixture was added gradually to ethanol (200 c.c.) and, when the reaction had moderated, the whole was heated on the water-bath under the reflux for 1 hour, after which the volatile portion was removed by distillation until the residual volume was ca. 100 c.c.; it was then poured into water (500 c.c.). The light brown precipitate of 3 : 3'-dinitro-1 : 1'-dinaphthyl (4.6 g.) was filtered off, washed acid free with water, crystallised once from nitrobenzene and twice from glacial acetic acid, and so obtained in golden yellow plates, m. p. 280—281° (Cumming and Howie, *loc. cit.*, give m. p. 281°; Chudožilov, *loc. cit.*, gives m. p. 262—264°) (Found : N, 8.3. Calc. for $C_{20}H_{14}O_4N_2$: N, 8.1%). This compound (2.4 g.), when boiled for 5 hours with glacial acetic acid (180 c.c.) and zinc dust (20 g.) during the gradual addition of hydrochloric acid (2 c.c., *d* 1.18), was reduced to 3 : 3'-diamino-1 : 1'-dinaphthyl which was removed from the cold reaction mixture, after it had been made alkaline with solid sodium hydroxide, by ether extraction; after removal of the ether from the dried extract, the residue of the crude 3 : 3'-diamino-1 : 1'-dinaphthyl crystallised from benzene in white plates, m. p. 269—270° (Cumming and Howie, *loc. cit.*, give m. p. 270°) (Found : N, 10.1. Calc. for $C_{20}H_{16}N_2$: N, 9.9%).

3 : 3'-Dinitro-4 : 4'-dihydroxy-1 : 1'-dinaphthyl.—This was formed when 3 : 3'-dinitro-4 : 4'-diamino-1 : 1'-dinaphthyl (2 g.) was refluxed with 20% aqueous sodium hydroxide (50 c.c.) for 2 hours; when the red disodium salt of the dihydroxy-compound began to be deposited, the mixture was filtered hot, and, on cooling, an almost quantitative yield was obtained in reddish-brown crystals (Found : Na, 10.8. $C_{20}H_{10}O_6N_2Na_2$ requires Na, 11.0%), which were sparingly soluble in cold but readily so in hot water. When the sodium salt was mixed with dilute acids, 3 : 3'-dinitro-4 : 4'-dihydroxy-1 : 1'-dinaphthyl was liberated and crystallised from glacial acetic acid in which it was moderately soluble in yellow micro-plates, m. p. 319—320° (Found : N, 7.6. $C_{20}H_{14}O_6N_2$ requires N, 7.4%).

3 : 3'-Diamino-4 : 4'-diacetamido-1 : 1'-dinaphthyl.—This was obtained when a solution of 3 : 3'-dinitro-4 : 4'-diacetamido-1 : 1'-dinaphthyl (2 g.) in boiling glacial acetic acid (150 c.c.) was treated gradually with zinc dust (20 g.) during 45 minutes, the mixture refluxed a further 30 minutes, and filtered hot into water (500 c.c.). The flocculent precipitate was extracted with boiling water (100 c.c.) containing hydrochloric acid (50 c.c., *d* 1.18) and the filtered extract cooled; the dihydrochloride of 3 : 3'-diamino-4 : 4'-diacetamido-1 : 1'-dinaphthyl then separated (1.2 g.) in white feathery needles which did not melt (Found : ionic chlorine, 14.9. $C_{24}H_{22}O_2N_4 \cdot 2HCl$ requires Cl, 15.1%), and were only sparingly soluble in cold water but readily so in hot water and dilute acids. After basification with dilute ammonia, the white precipitate of 3 : 3'-diamino-4 : 4'-diacetamido-1 : 1'-dinaphthyl was crystallised from glacial acetic acid, giving white micro-crystals which carbonised at 390° (Found : N, 13.9. $C_{24}H_{22}O_2N_4$ requires N, 14.1%), and were almost insoluble in benzene, xylene, or ethanol.

1 : 1'-Diacetamido-2 : 2'-dinaphthyl.—This was prepared by stirring a suspension of 1 : 1'-diamino-2 : 2'-dinaphthyl (1.7 g.) in acetic anhydride (25 c.c.) for 24 hours at room temperature (cf. Cumming and Howie, *J.*, 1932, 531); attempts to make this compound more rapidly by hot acetylation resulted in the formation of 1 : 2 : 7 : 8-dibenzocarbazole, which crystallised from benzene in white needles, m. p. 216° (Bucherer and Schmidt, *J. pr. Chem.*, 1909, 79, 375, give m. p. 216°) (Found : N, 5.4. Calc. for $C_{20}H_{12}N_2$: N, 5.2%).

Dinitration of 1 : 1'-Diacetamido-2 : 2'-dinaphthyl.—1 : 1'-Diacetamido-2 : 2'-dinaphthyl (0.95 g.) was stirred into nitric acid (25 c.c., *d* 1.42) below 15°. After 30 minutes' stirring, 4 : 4'-dinitro-1 : 1'-diacetamido-1 : 1'-dinaphthyl began to separate, and at this stage the mixture was poured into water (120 c.c.), and the precipitated dinitro-compound (0.5 g.) dissolved in a hot mixture of glacial acetic acid and xylene (1 : 1) from which it separated in light yellow micro-needles, m. p. 341—342° (Found : N, 12.5. $C_{24}H_{18}O_4N_4$ requires N, 12.3%). When this compound (1 g.) was refluxed for 10 hours with ethanol (10 c.c.) and sulphuric acid (10 c.c., *d* 1.08), and the mixture poured into water, there separated 3 : 6-dinitro-1 : 2 : 7 : 8-dibenzocarbazole which crystallised from nitrobenzene in yellow micro-crystals; these had no m. p. but sintered at ca. 385° (cf. Hodgson and Habeshaw, *loc. cit.*) (Found : N, 12.1. Calc. for $C_{20}H_{14}O_4N_4$: N, 11.8%).

311. The Formation of Hydroxythionaphthens by the Interaction of Benzenesulphonylbenzothiazolone and Substances containing a Reactive Methylene Group.

By A. W. H. BARTON and (the late) E. W. MCCLELLAND.

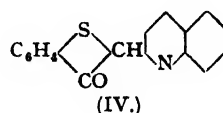

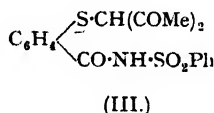

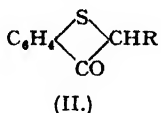

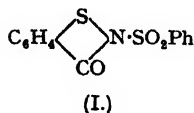

The isothiazolone (I) reacts with substances containing a reactive methylene group, in presence of pyridine or piperidine, with elimination of benzenesulphonamide, to give 2-substituted derivatives of 3-hydroxythionaphthen of type (II). The group R found in the product is the acetyl, propionyl or butyryl group with the respective aliphatic ketones, and the carbethoxy-group with ketonic esters, but reaction proceeds further in the case of acetone yielding a dithionaphthenyl ketone. Benzoylacetone and acetophenone yield 3-hydroxy-2-benzoylthionaphthen. α -Picoline and quinaldine give the 3-hydroxy-2-2'-pyridyl- and -quinolyl-thio-

naphthen. The mechanism of the reaction is discussed, the isolation of the substance (III) as the immediate product from acetylacetone being significant.

A remarkable reaction also occurs when the isothiazolone is heated with ethyl phenylacetate and pyridine or quinoline, pyridyl- or quinolyl-thionaphthen being produced.

THE work of Smiles and his collaborators (*J.*, 1912, 101, 570; 1915, 107, 1378; 1921, 119, 1810; 1924, 125, 876) showed that 3-hydroxythionaphthen and certain of its 2-derivatives could be prepared by warming together in sulphuric acid *o*-mercaptobenzoic acid and various substances such as malonic and acetoacetic esters, β -diketones, and malic or citric acid. The yields are, however, not always satisfactory, tarry by-products and thioindigotin being often present, and the reaction sometimes fails owing to the prior decomposition of the diketonic reagent.

It has now been found that the readily accessible benzenesulphonylbenzisothiazolone (I) reacts smoothly with various substances containing a reactive methylene group to produce good yields of 2-substituted derivatives of 3-hydroxythionaphthen (II), benzenesulphonamide being simultaneously eliminated.

The reaction with ethyl malonate, ethyl acetoacetate, or ethyl acetonedicarboxylate in presence of pyridine or piperidine gives 3-hydroxy-2-carbethoxythionaphthen (II, R = CO₂Et). When the thiazolone is heated with acetylacetone in boiling alcohol or toluene in the absence of any basic catalyst, a direct *addition compound* (III) results, which is converted by the action of alkalis or by heating in boiling pyridine into 3-hydroxy-2-acetylthionaphthen (II, R = COMe) and benzenesulphonamide: this same acetylthionaphthen is obtained directly when the original reaction with acetylacetone is conducted in boiling pyridine solution. The properties of the addition compound are consistent with structure (III), which is also supported by the analogy with the products of addition of the benzisothiazolone to aromatic amines, whose structure has been firmly established (McClelland and Peters, this vol., p. 1229).

From benzoylacetone the corresponding 3-hydroxy-2-benzoylthionaphthen (II, R = C(=O)Ph) is formed.

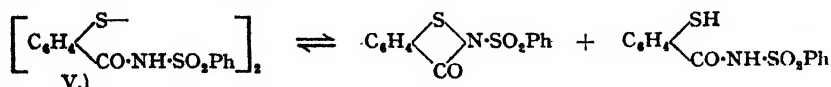

A reaction of the same kind takes place with ketones in general, but only in the presence of piperidine as catalyst. For instance, methyl ethyl ketone yields 3-hydroxy-2-propionylthionaphthen previously described by Krollpfeifer and Schneider (*Ber.*, 1928, 61, 1284), methyl *n*-propyl ketone gives 3-hydroxy-2-butyrylthionaphthen, and acetophenone the corresponding benzoylthionaphthen, while *m*-nitroacetophenone gives 3-hydroxy-2-*m*-nitrobenzoylthionaphthen.

With acetone the main product is 3:3'-dihydroxy-2:2'-dithionaphthenyl ketone (compare Friedländer and Risse, *Ber.*, 1914, 47, 1928) but a small amount of 3-hydroxy-2-acetylthionaphthen is obtained and may be an intermediate in the process. The latter substance does in fact condense further with the benzisothiazolone under the conditions of the reaction.

The reaction with diethyl ketone gave 3-hydroxy-2-methylthionaphthen, identified in the form of its oxidation product 2:2'-bis-(3-hydroxy-2-methylthionaphthen) (compare McClelland and D'Silva, *J.*, 1931, 2972), together with some 3-hydroxy-2-propionylthionaphthen, the formation of which seems inexplicable unless it was due to the presence of methyl ethyl ketone as an impurity.

Quinaldine and α -picoline also condense with benzenesulphonylbenzisothiazolone, yielding 3-hydroxy-2:2'-quinolylthionaphthen (IV), and the analogous pyridylthionaphthen.

Benzisothiazolone itself did not react with boiling acetone and its reaction with methyl ethyl ketone and quinaldine was slow. The benzisothiazolone when heated alone in boiling pyridine was reduced to di-*N*-benzenesulphonyl-2:2'-dithiobenzamide (V), and when the main condensation was slow (*e.g.*, with diethyl ketone) this disulphide (V) was sometimes found as a by-product. According to the dismutation theory (McClelland and Warren, *J.*, 1930, 1095; D'Silva and McClelland, *J.*, 1932, 2883) the disulphide and the benzisothiazolone are reversibly interconvertible thus:

It was found, in fact, that the dithiobenzamide (V) also condensed with acetylacetone slowly in boiling alcohol and somewhat faster in boiling pyridine.

No reaction could be detected between benzenesulphonylbenzisothiazolone and ethyl phenylacetate at 170° in presence of piperidine, but when pure quinoline was also present 3-hydroxy-2-2'-quinolylthionaphthen resulted, and with pyridine the analogous pyridylthionaphthen was again produced. These products were formed only when all three reactants were present, but the result has not been explained. When dimethylaniline was substituted for quinoline, an intensely blue substance was found in addition to 2-*N*-benzenesulphonylcarbonyl-4'-dimethylaminodiphenyl sulphide (cf. McClelland and Peters, *loc. cit.*), but its nature has not been elucidated.

EXPERIMENTAL.

Reactions of Benzenesulphonylbenzisothiazolone with Ketonic Substances.—Acetylacetone. The benzisothiazolone (5 g.) was heated in boiling ethyl alcohol (70 c.c.) with acetylacetone (3 g.) for 2 hours. On cooling, 3-(2'-benzenesulphonylcarbonylphenyl-1'-thio)pentane-2:4-dione (III) crystallised out (yield 94%). It forms white plates, m. p. 163° (decomp.) (Found: C, 55.1; H, 4.4; S, 16.6. $C_{11}H_{11}O_2NS_2$ requires C, 55.2; H, 4.4; S, 16.4%). This substance gives a red coloration with ferric chloride. It is soluble in benzene or hot methyl or ethyl alcohol but insoluble in ether or hot water. It was unchanged by heating in boiling toluene for 6 hours. Attempts to methylate, acetylate, or dehydrate it were unsuccessful. It dissolves in cold aqueous sodium hydroxide and is reprecipitated unchanged on acidification. After the alkaline solution had been boiled for $\frac{1}{2}$ hour it contained a thionaphthen, as shown by the formation of thioindigotin with potassium ferricyanide, and distillation of the solution in a current of steam yielded 3-hydroxy-2-acetylthionaphthen (m. p. 79°, not depressed by admixture of an authentic specimen), which was converted by phenylhydrazine into 1-phenyl-3-methyl-4:5-thionaphthenopyrazole, m. p. 120° (cf. Barry and McClelland, *J.*, 1935, 472). Benzenesulphonamide was deposited from the solution on cooling.

The addition compound yielded the same acetylthionaphthen when boiled in pyridine for 2 hours or heated at 40° for 4 hours with concentrated sulphuric acid.

Good yields of the same product were obtained direct by heating the benzisothiazolone with acetylacetone in pyridine for 3 hours.

The corresponding reaction of 1-*p*-toluenesulphonylbenzisothiazolone with acetylacetone in alcohol yielded 3-(2'-*p*-toluenesulphonylcarbonylphenyl-1'-thio)pentane-2:4-dione, white plates, m. p. 180° (decomp.), from alcohol (Found: C, 56.4; H, 4.6. $C_{10}H_{10}O_2NS_2$ requires C, 56.3; H, 4.7%), which on being heated in pyridine gave the 3-hydroxy-2-acetylthionaphthen and *p*-toluenesulphonamide.

Condensation of the benzisothiazolone with the diketonic substances, with pyruvic acid, and with *m*-nitroacetophenone was carried out by boiling equimolecular quantities together in pyridine. The reaction with ketones (4–6 mols., or an excess as solvent) took place in presence of a few drops of piperidine, the ketone itself or chloroform being used as solvent. Benzenesulphonamide was isolated as a by-product in every case.

Ethyl malonate. This did not react with the thiazolone in the absence of a basic catalyst. The mixture, after 4 hours' heating in boiling pyridine, was poured into dilute acid. The precipitated oil solidified, and was distilled in a current of steam. 3-Hydroxy-2-carbethoxythionaphthen was thus isolated (yield 79%); it separated from alcohol in white plates, m. p. 74° (Found: C, 58.9; H, 4.2. Calc.: C, 59.5; H, 4.5%) (cf. Arndt, Hirsch, and Nachtwey, *Ber.*, 1926, 59, 1077). Hydrolysis by 2*N*-sodium hydroxide at 100° yielded 3-hydroxythionaphthen, m. p. 70°, further converted into the thionaphthindole of m. p. 251° (McClelland and D'Silva, *J.*, 1932, 229).

Ethyl acetoacetate. This ester gave 3-hydroxy-2-carbethoxythionaphthen (yield 80%). When this was distilled in steam, a tarry residue was left from which cold alcohol separated some yellow 3:5'-dihydroxy-1:1'-dithionaphthenyl ketone which constitutes the main product from acetone.

When the reaction was carried out in ethyl alcohol with a little pyridine as catalyst the carbethoxythionaphthen and unchanged thiazolone were alone isolated, showing that the intermediate compound is unstable under these conditions.

Benzoyl acetone. The reaction mixture after 6 hours' boiling in pyridine was poured into dilute acid. The solid precipitated was distilled in a current of steam, to remove unchanged diketone, and then extracted with hot alcohol, from which 3-hydroxy-2-benzoylthionaphthen was deposited in yellow needles, m. p. 116 (Smiles and Ghosh, *J.*, 1915, 107, 1378).

Acetone. When the benzisothiazolone had been heated in boiling acetone with 2 drops of piperidine for 4 hours, yellow needles, m. p. 234°, were deposited which were identified as 3:3'-dihydroxy-2:2'-dithionaphthenyl ketone (Friedländer and Risse, *loc. cit.*) (Found: C, 62.7; H, 3.2; S, 19.6. Calc.: C, 62.6; H, 3.1; S, 19.7%), giving the diacetyl derivative, m. p. 183° (Found: C, 61.2; H, 3.3. Calc.: C, 61.5; H, 3.4%). A little 3-hydroxy-2-acetylthionaphthen was also found.

When the benzisothiazolone (2 g.) was heated in boiling benzene (100 c.c.) with the hydroxyacetylthionaphthen (1.5 g.) and 2 drops of piperidine for 7 hours the same dithionaphthenyl ketone was produced (yield 68%).

Methyl ethyl ketone. Under similar conditions this ketone furnished 3-hydroxy-2-propionylthionaphthen, m. p. 74° (Krollpfeifer and Schneider, *loc. cit.*) (Found: C, 64.3; H, 5.1. Calc.: C, 64.1; H, 4.9%) (yield 57%, but this was improved by warming the mixture for 5 minutes and keeping it for 10 days).

*Methyl *n*-propyl ketone.* The benzisothiazolone was boiled with the ketone and 6 drops of piperidine in chloroform solution for 7 hours. The mixture was diluted with ether, the solution washed successively with dilute acid and water, and evaporated. When the residue was distilled in a current of steam, the oil which came over solidified, and the 3-hydroxy-2-*n*-butyrylthionaphthen crystallised from

methyl alcohol in white needles, m. p. 36° (Found: C, 65.5; H, 5.7. $C_{15}H_{11}O_2S$ requires C, 65.5; H, 5.5%). This substance is slightly soluble in aqueous sodium hydroxide and slowly gives thio-indigotin on shaking with alkaline ferricyanide. It gives a greenish-violet ferric chloride reaction. This and the preceding propionyl compound failed to react with phenylhydrazine in boiling alcohol in presence of a little sulphuric acid after 6 hours' heating.

Acetophenone. After the reaction, the excess of ketone was removed in a current of steam. The residue was 3-hydroxy-2-benzoylthionaphthen, crystallising from alcohol in pale yellow needles, m. p. 117° (Smiles and Ghosh, *loc. cit.*).

Pyruvic acid. The product from the condensation, isolated by pouring into acid and collecting the precipitate, was 3-hydroxythionaphth-2-ylglyoxylic acid, yellow plates, m. p. 174°, after drying at 100° (Hart and Smiles, *J.*, 1924, 125, 876).

m-Nitroacetophenone. After 6 hours' boiling of the reaction mixture, the product crystallised on cooling. It was collected, and washed with pyridine, dilute acid, and water. 3-Hydroxy-2-m-nitro-benzoylthionaphthen crystallises from alcohol in pale yellow needles, m. p. 203° (Found: C, 60.0; H, 2.9; N, 5.1. $C_{15}H_{11}O_4NS$ requires C, 60.2; H, 3.0; N, 4.7%).

Diethyl ketone. The thiazolone was heated for 12 hours in boiling diethyl ketone with a little piperidine, the solvent evaporated, and the residue distilled in steam. The oil which slowly distilled was collected in ether, dried (Na_2SO_4), and the solvent evaporated. 3-Hydroxy-2-methylthionaphthen was thus isolated as a yellow viscous oil soluble in aqueous sodium hydroxide. It was converted by hot alkaline ferricyanide into 2:2'-bis-(3-hydroxy-2-methylthionaphthen), m. p. 151° (cf. McClelland and D'Silva, *loc. cit.*), and by hydrogen peroxide in glacial acetic acid into the dioxide, m. p. 110°. Further steam distillation after acidification of the mixture yielded a little 3-hydroxy-2-propionylthionaphthen, m. p. 70°, while benzenesulphonamide and di-N-benzenesulphonyl-2:2'-dithiobenzamide, m. p. 226°, were found in the mother-liquor.

Ethyl acetonedicarboxylate. This ester condensed with the benzisothiazolone on boiling in chloroform for 7 hours with a little piperidine. The solution was evaporated, and the residue acidified and distilled in a current of steam, whereupon 3-hydroxy-2-carbethoxythionaphthen came over (yield 86%).

Reaction of Benzenesulphonylbenzisothiazolone with Quinaldine and α -Picoline.—The thiazolone (4 g.) was boiled in chloroform (30 c.c.) for 6 hours with quinaldine (4 g.) and 2 drops of piperidine, the solution evaporated, and the excess of base removed in a current of steam. The remaining solid (yield 92%) was 3-hydroxy-2-2'-quinolylthionaphthen (IV), which crystallised from benzene in ruby-red prisms, m. p. 184° (Found: C, 73.6; H, 4.1; N, 5.2. $C_{17}H_{11}ONS$ requires C, 73.6; H, 4.0; N, 5.1%). Similar results but lower yields were obtained by using pyridine or glacial acetic acid as solvent. This substance is soluble in alcohol, chloroform, or hot acetic acid, giving blood-red solutions. It turns yellow with alkali or concentrated mineral acids, dissolving in the latter. Hydrochloric acid produced an unstable yellow substance, m. p. 117°, presumably a hydrochloride, which was reconverted into the parent substance by water.

Oxidation with ferricyanide in piperidine solution produced a white amorphous solid (purified from hot nitrobenzene) of m. p. 273° (sublimes). This is 2:2'-bis-(3-hydroxy-2-2'-quinolylthionaphthen) (Found: C, 73.7; H, 3.8. $C_{34}H_{20}O_6N_2S_2$ requires C, 73.9; H, 3.6%). The acetyl derivative of (IV) forms white plates, m. p. 177°, from acetic anhydride (Found: C, 71.4; H, 4.0. $C_{17}H_{11}O_3NS$ requires C, 71.5; H, 4.1%) and is hydrolysed rapidly by acids or alkalis and slowly by water or boiling alcohol.

The thiazolone was boiled with half its weight of α -picoline in glacial acetic acid for 5 hours. The product, which separated on cooling (yield 83%), crystallised from alcohol in fawn needles, m. p. 132°, of 3-hydroxy-2-2'-pyridylthionaphthen (Found: C, 68.8; H, 3.9. $C_{15}H_9ONS$ requires C, 68.7; H, 4.0%). A similar result was obtained by heating the thiazolone with α -picoline hydrochloride in boiling pyridine, but when the reagents were heated in chloroform with piperidine or in picoline alone as solvent the product was di-N-benzenesulphonyl-2:2'-dithiobenzamide.

The hydroxypyridylthionaphthen is soluble in hot alcohol or acetic acid or hot aqueous sodium hydroxide. It gives a yellow solution in mineral acids. It is slightly volatile in steam. Its acetyl derivative crystallises from acetic anhydride in massive white prisms, m. p. 133° (considerably depressed by adding the parent substance) (Found: C, 66.9; H, 4.0. $C_{15}H_{11}O_3NS$ requires C, 66.9; H, 4.1%).

Reaction of Unsubstituted Benzisothiazolone with Ketones and Quinaldine.—No reaction was detected when benzisothiazolone was boiled for 12 hours in acetone in presence of piperidine. With methyl ethyl ketone a very little hydroxypropionylthionaphthen was formed. With quinaldine after 8 hours' boiling in glacial acetic acid the hydroxyquinolylthionaphthen was produced in 32% yield.

Condensation with Ethyl Phenylacetate.—This ester (10 g.) would not react with benzenesulphonylbenzisothiazolone (5 g.) in presence of piperidine at 170°, but when pure quinoline (10 g.) was also present reaction had occurred after 5 hours' heating. The excess of reagents and solvent was removed from the red mixture in a current of steam, and the tarry product extracted with hot aqueous sodium hydroxide. The solution was decanted, cooled, and saturated with carbon dioxide. The red precipitate proved to be 3-hydroxy-2-2'-quinolylthionaphthen, m. p. 189° (yield 42%), and benzenesulphonamide was present in the mother-liquors.

In the same way benzenesulphonylbenzisothiazolone, heated with an equal weight of ethyl phenylacetate in boiling pure pyridine for 7 hours, gave 3-hydroxy-2-2'-pyridylthionaphthen, m. p. 133° (yield 39%), and the benzenesulphonyldithiobenzamide. No hydroxyphenylthionaphthen could be detected in these reactions.

The benzenesulphonylbenzisothiazolone also reacted when heated for 5 hours at 170° with ethyl phenylacetate and dimethylaniline in presence of piperidine. The products isolated immediately were benzenesulphonamide, the benzenesulphonyldithiobenzamide, 2-N-benzenesulphonylcarbonyl-4'-dimethylaminodiphenyl sulphide, m. p. 172°, and an intensely blue substance remained in the mother-liquor. This was collected chromatographically on anhydrous alumina, removed in alcohol, and recovered as a blue solid which separates from chloroform-petroleum in blue plates with a golden iridescence, m. p. 198°. It is stable to alkalis, gives yellow solutions in acids, and with hydrogen peroxide

in acetic acid yields a substance of m. p. 214°. The formation of this blue compound requires the presence of the thiazolone, the ester, the dimethylaniline, and the catalyst, but it was also observed when 2 : 2'-dithiobenzoic acid replaced the first of these or when benzyl cyanide replaced the ester.

Di-N-benzenesulphonyl-2 : 2'-dithiobenzamide as a Possible Intermediate in the Reactions.—Benzenesulphonylbenzothiazolone, boiled for 2 hours in pyridine, gave the dithiobenzamide, m. p. 226° (yield 60%).

The dithiobenzamide (0.5 g.), heated for 2 hours in boiling alcohol with acetylacetone (0.3 g.), gave, in addition to some recovered dithiobenzamide, 3-(2'-benzenesulphonylcarbamyphenyl-1'-thio)pentane-2 : 4-dione, m. p. 163° (yield 29%).

The dithiobenzamide, heated in boiling pyridine for 3 hours with acetylacetone (2 mols.), gave 3-hydroxy-2-acetylthionaphthen (yield 44%) and benzenesulphonamide.

312. Researches on Acetylenic Compounds. Part XI. The Mannich Reaction with Monosubstituted Acetylenic Compounds.

By E. R. H. JONES, I. MARSZAK, and (in part) H. BADER.

The scope of the Mannich reaction with mono-substituted acetylenic compounds, previously only applied to activated substances such as phenyl- and vinyl-acetylenes, has been extended to include alkylacetylenes and several types of acetylenic alcohols. Excellent yields are obtainable except with the α -ethynylcarbinols [containing the grouping $>C(OH)\cdot C\equiv CH$], but their acetates react normally. No suggestions for this anomalous behaviour can as yet be offered.

THE application of the well-known Mannich reaction (for summary see Blicke, "Organic Reactions," 1942, I, p. 303) in the acetylenic series has hitherto been restricted to compounds containing an activated ethynyl group, *e.g.*, phenyl- and substituted phenyl-acetylenes (Mannich and Chang, *Ber.*, 1933, 66, 418) and vinylacetylene (Coffman, *J. Amer. Chem. Soc.*, 1935, 57,

1978; Carothers and du Pont, U.S.P. 2,110,199). With acetylene itself the reaction has to be effected under pressure in the presence of a copper acetylide catalyst, under which conditions propargylamines ($HC\equiv C\cdot CH_2\cdot NR_2$) and the corresponding diamines are formed, the former preponderating (I.G. Farb., B.P. 510,904; U.S.P. 2,273,141).

The present study was undertaken with a view to extending the scope of the Mannich reaction to various types of acetylenic compounds. During the progress of this work information became available that some similar studies had been made in Germany (B.I.O.S. Final Report No. 266; item No. 22) and although no experimental details are available, it seems that copper catalysts were invariably employed.

In all the reactions described in this paper the appropriate reagents were heated in dioxan solution at about 80° in nitrogen. 1-Hexyne, the only hydrocarbon examined, gave a 75% yield of 1-diethylaminohept-2-yne (I). α -Ethynylcarbinols of type (II), invariably gave exceed-

ingly poor yields of the expected amines, but their acetates on the other hand behaved normally and yields of amines (III) ranging from 50 to 90% were obtained with the acetates of representative primary, secondary, and tertiary carbinols. The inhibiting effect of the hydroxyl group is apparently restricted to the α -position since the β -ethynylcarbinol [$CH_2\cdot CH(OH)\cdot CH_2\cdot C\equiv CH$] gave a 60% yield of amine. With conjugated ethynyl-ethylenic carbinols such as (IV) no inhibiting effect of the hydroxyl groups was observed, 80–85% yields of the expected amines being achieved both with the carbinols themselves and with their acetates. The products in these cases all exhibited similar light absorption properties in the ultra-violet, arising from the presence of the conjugated ethylenic-acetylenic chromophore.

The partial and complete hydrogenation and also other reactions of the acetylenic amino-alcohols described in this paper are being studied and will be reported on in a subsequent communication.

EXPERIMENTAL.

Light-absorption data were determined in alcoholic solutions.

1-Diethylaminohept-2-yne (I).—To a warm solution of diethylamine (16 g.) and trioxymethylene (7.2 g.) in dioxan (20 c.c.), a solution of 1-hexyne (16.4 g.) in dioxan (10 c.c.) was added and the mixture

was heated on a steam-bath for 15 hours in an atmosphere of nitrogen. Ether was added, and the basic product was isolated by washing with 2*N*-hydrochloric acid and then liberated with sodium hydroxide (10%). After ether extraction, drying (Na_2SO_4), and evaporation, distillation gave 1-diethylaminohept-2-yne (25.7 g.; 77%), b. p. $100^\circ/20$ mm., n_D^{25} 1.4513 (Found: C, 78.95; H, 12.5. $\text{C}_{11}\text{H}_{21}\text{N}$ requires C, 78.95; H, 12.6%). The *picrate*, prepared in methanol, crystallised from this solvent as long prisms, m. p. 75° (Found: C, 51.8; H, 6.2. $\text{C}_{17}\text{H}_{24}\text{O}_7\text{N}_4$ requires C, 51.5; H, 6.1%).

1-Dimethylamino-4-acetoxyprop-2-yne.—A mixture of dimethylamine (6 g.), trioxymethylene (4.7 g.), and propargyl acetate (12 g.) in dioxan (25 c.c.) was heated for 34 hours on a steam-bath. The *amine* (8.8 g.) had b. p. $65^\circ/0.7$ mm., n_D^{25} 1.4531 (Found: C, 61.55; H, 8.85. $\text{C}_8\text{H}_{13}\text{O}_2\text{N}$ requires C, 61.9; H, 8.45%). The *methiodide* crystallised from methanol-ether in prisms, m. p. 140° (Found: C, 36.75; H, 5.55. $\text{C}_8\text{H}_{14}\text{O}_2\text{NI}$ requires C, 36.35; H, 5.45%).

1-Diethylamino-4-acetoxyhept-2-yne (III; R = H; $\text{R}_1 = n\text{-Pr}$).—The standard method (20 hours' heating) employed with diethylamine (8 g.), trioxymethylene (3.9 g.), and 3-acetoxyhex-1-yne (14 g.; Bowden, Heilbron, Jones, and Weedon, *J.*, 1946, 45) in dioxan (15 c.c.) gave the *amine* (20 g.), b. p. $81^\circ/0.1$ mm., n_D^{25} 1.4546 (Found: C, 69.2; H, 10.4. $\text{C}_{13}\text{H}_{23}\text{O}_2\text{N}$ requires C, 69.25; H, 10.3%). The same base was obtained, but in poorer yield, by carrying out the reaction at 20° . The *oxalate* crystallised from ethanol-ether as fine prisms, m. p. 90.5° (Found: C, 57.2; H, 7.65. $\text{C}_{11}\text{H}_{23}\text{O}_6\text{N}$ requires C, 57.1; H, 8.0%).

1-Diethylamino-1'-acetoxy-3-cyclohexylprop-2-yne (III; $\text{RR}' = \text{C}_6\text{H}_{10}$).—Diethylamine (12 g.), trioxymethylene (5.4 g.), and ethynylcyclohexanyle acetate (24.9 g.) in dioxan (25 c.c.) after being heated for 30 hours gave the *amine* (29.7 g.), b. p. $111^\circ/0.6$ mm., n_D^{25} 1.4806 (Found: C, 71.95; H, 10.25. $\text{C}_{15}\text{H}_{25}\text{O}_2\text{N}$ requires C, 71.65; H, 10.05%). The *picrate* crystallised from methanol in plates, m. p. 114° (Found: C, 52.6; H, 5.9. $\text{C}_{21}\text{H}_{29}\text{O}_8\text{N}_4$ requires C, 52.45; H, 5.9%).

1-Diethylaminohex-2-yn-5-ol.—After a mixture of diethylamine (12.4 g.), trioxymethylene (6.75 g.), and pent-1-yn-4-ol (12.6 g.; Haynes and Jones, *J.*, 1946, 956) had been heated on a steam-bath for 30 hours, the *amine* (15 g.) was isolated with b. p. $73^\circ/0.1$ mm., n_D^{25} 1.4740 (Found: C, 71.0; H, 11.45. $\text{C}_{10}\text{H}_{19}\text{ON}$ requires C, 70.95; H, 11.3%). The *picrate* crystallised from benzene in prisms, m. p. 78° (Found: C, 48.4; H, 5.65. $\text{C}_{16}\text{H}_{23}\text{O}_6\text{N}_4$ requires C, 48.2; H, 5.55%).

1-Diethylaminohex-4-en-2-yn-6-ol.—A mixture of diethylamine (16 g.), trioxymethylene (7.2 g.), and pent-2-en-4-yn-1-ol (16.4 g.; Haynes, Heilbron, Jones, and Sondheimer, Part XIII, this vol., p. 1583) in dioxan (25 c.c.) on being heated for 25 hours on a steam-bath gave the *amine* (25.4 g.), b. p. $135^\circ/1$ mm., n_D^{25} 1.5102 (Found: C, 72.1; H, 10.25. $\text{C}_{10}\text{H}_{17}\text{ON}$ requires C, 71.8; H, 10.25%). Light absorption: Maximum, 2270 Å.; $\epsilon = 15,500$. Inflection, 2370 Å., $\epsilon = 12,500$. The *a-naphthylurethane* crystallised from petroleum (b. p. $80\text{--}100^\circ$) in plates, m. p. 79° (Found: C, 75.05; H, 7.4. $\text{C}_{21}\text{H}_{26}\text{O}_2\text{N}_2$ requires C, 74.95; H, 7.2%).

1-Diethylaminohex-4-en-2-yn-6-ol.—The standard method (36 hours' heating) employed with diethylamine (12.4 g.), trioxymethylene (6 g.), and hex-3-en-5-yn-2-ol (13.8 g.; Heilbron, Jones, and Weedon, *J.*, 1945, 81) in dioxan (20 c.c.) gave the *amine* (21 g.), b. p. $85^\circ/0.1$ mm., n_D^{25} 1.5003 (Found: C, 73.1; H, 10.75. $\text{C}_{11}\text{H}_{19}\text{ON}$ requires C, 72.85; H, 10.55%). Light absorption: Maximum, 2270 Å.; $\epsilon = 15,000$. Inflection, 2350 Å.; $\epsilon = 13,000$. The *picrate*, prepared in methanol, crystallised from benzene in plates, m. p. 118° (Found: C, 49.95; H, 5.55. $\text{C}_{17}\text{H}_{22}\text{O}_6\text{N}_4$ requires C, 49.75; H, 5.4%).

1-Dimethylamino-6-acetoxyhept-4-en-2-yne.—A mixture of dimethylamine (5 g.), trioxymethylene (3.6 g.), and 2-acetoxyhex-3-en-5-yne (13.8 g.; Jones and McCombie, *J.*, 1943, 261) in dioxan (30 c.c.) after being heated for 24 hours on a steam-bath gave the *amine* (16.2 g.), b. p. $72^\circ/0.5$ mm., n_D^{25} 1.4808 (Found: C, 68.15; H, 8.7. $\text{C}_{11}\text{H}_{19}\text{O}_2\text{N}$ requires C, 67.65; H, 8.8%). The *methoperchlorate* crystallised from methanol-ether in plates, m. p. 112.5° (Found: C, 46.75; H, 6.35. $\text{C}_{11}\text{H}_{20}\text{O}_6\text{NCl}$ requires C, 46.5; H, 6.5%).

1-Diethylamino-6-acetoxyhept-4-en-2-yne.—Prepared as above using diethylamine (8 g.) instead of dimethylamine, the *amine* (19.1 g.) had b. p. $108\text{--}110^\circ/1$ mm., n_D^{25} 1.4800 (Found: C, 69.5; H, 9.4. $\text{C}_{13}\text{H}_{21}\text{O}_2\text{N}$ requires C, 69.9; H, 9.5%).

The authors thank Sir Ian Heilbron, D.S.O., F.R.S., for his interest and encouragement and Dr. E. A. Braude for the light-absorption data.

313. Researches on Acetylenic Compounds. Part XII. The Preparation of Conjugated Diacetylenic Glycols by the Oxidative Coupling of Various Types of Ethynylcarbinols.

By K. BOWDEN, SIR IAN HEILBRON, E. R. H. JONES, and K. H. SARGENT.

Contrary to the experiences of earlier workers it has now been found that the coupling of ethynylcarbinols to diacetylenic glycols, by aerial oxidation in the presence of cuprous ammonium chloride, is a general reaction applicable to carbinols of various types. The scope of synthetic reactions with acetylenic compounds is thereby considerably extended, and these interesting glycols become readily available for more detailed study. Moreover, the function of the cuprous salt appears to be largely catalytic, and coupling can be effected with the use of much less than one equivalent of cuprous ammonium chloride. Light-

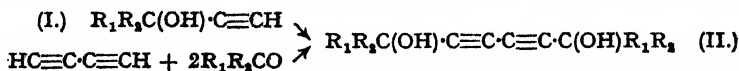

absorption data for the conjugated diacetylene chromophore are recorded and compared with those of conjugated diene and vinylacetylene systems.

THE formation of diacetylenes by the oxidative coupling of metallic derivatives of mono-substituted acetylenes was first observed as early as 1869, and several alternative procedures have since been described. These mainly involve oxidation of either the cuprous or the

halogenomagnesium acetylides with agents such as oxygen, ferricyanide, cupric salts, etc. (For summary and references see "The Chemistry of Acetylene," Nieuwland and Vogt, Reinhold, New York, 1945.) Cupric acetylides are apparently unstable, and, in all reactions in which they should be produced, coupling to diacetylenes occurs.

The oxidation of the readily-available ethynylcarbinols (*e.g.*, I) is of particular importance and interest since it provides facile synthetic routes to bifunctional compounds difficult to prepare by other means. This is especially true since the only alternative route to the

diacetylenic glycols (II), *i.e.*, via diacetylene, is ruled out because of the practical difficulties involved in preparing this hydrocarbon in quantity. It should be noted, however, that diacetylene has become available in Germany in recent years as a by-product (7%) in the Huels arc process for the production of acetylene from gaseous hydrocarbons.

Zal'kind and his collaborators (*J. Gen. Chem. Russia*, 1937, 7, 227; 1939, 9, 971, 1725; *Ber.*, 1936, 69, 128) reported that aerial oxidation of the cuprous acetylides of tertiary ethynylcarbinols at room temperature gave good yields of the corresponding diacetylenic glycols, but that only very indifferent yields could be obtained with secondary ethynylcarbinols. These authors sought a theoretical explanation of this lack of reactivity of the secondary carbinols in terms of the opposing inductive effects of the hydroxyl and alkyl groups involved.

It has now been ascertained that by carrying out the aerial oxidation at somewhat higher temperatures, *e.g.* in the range 50–70°, coupling of a wide variety of ethynylcarbinols can be achieved, in most cases to give excellent yields. Methyl-, propyl-, and phenyl-ethynylcarbinols give the secondary glycols (III; R = Me, Pr, and Ph respectively) as mixtures of the *dl*- and *meso*-forms. The reaction can be extended to carbinols made from alkylene oxides giving the glycols (IV; R = H and Me), the latter again probably as a mixture of stereoisomerides. The

glycol derived from ethylene oxide (*i.e.*, IV; R = H), the structure of which has been proved by hydrogenation to octane-1:8-diol, is remarkably unstable, being very readily converted into a scarlet insoluble pigment by what appears to be a photo-catalysed oxidation.

Not only can simple ethynylcarbinols be coupled up by this process, but even conjugated ethynylethylenic carbinols such as hexenynol [$CH_3\cdot CH(OH)\cdot CH=CH\cdot C\equiv CH$] can be oxidised. The glycol (V) obtained from this carbinol is a crystalline solid, presumably stereochemically pure, and its structure is proved by its hydrogenation to dodecane-2:11-diol, which on oxidation gives sebacic acid. Another example of this type is furnished in Part XIV (p. 1586) where the light-absorption data for the chromophore present in glycols such as (V) are discussed.

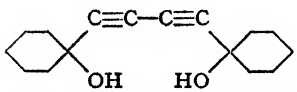

In addition to demonstrating the general nature of this oxidative coupling reaction, it has also been shown, contrary to earlier work in this field, that it is unnecessary to employ a large excess of cuprous ammonium chloride. While this work was in progress information became available that the I.G. Farb. at Ludwigshafen had effected the oxidation of propargyl alcohol to hexadienediol using only catalytic quantities of cuprous salt. Three representative glycols (II, R₁ = Me, R₂ = Et; II, R₁R₂ = CH₃ < [CH₂]₄ >; and III, R = Pr) have been prepared in this way, by employing 0.2–0.5 equivalent of cuprous chloride. Although the process is rendered somewhat slower and higher reaction temperatures have to be employed, the yields remain excellent.

The light-absorption properties of the diacetylenic glycols, recorded in the accompanying Table, agree with those previously determined for 2:7-dimethylocta-3:5-diyne-2:7-diol (II; R₁ = R₂ = Me) (mentioned by Jones and McCombie, *J.*, 1943, 261). The conjugated diacetylene chromophore exhibits absorption at rather longer wave-lengths than conjugated vinylacetylenes and dienes, but the intensities are only of a very low order. The progressive

diminution in intensity and the accompanying appearance of fine structure in the conjugated diene, en-yne, and di-yne systems is of some interest.

Various aspects of the chemistry of these readily accessible diacetylenic glycols are at present being studied in these laboratories.

Light-absorption data of conjugated diacetylenic glycols compared with those of conjugated dienes and vinylacetylenes.

³ This band may arise from the presence of a small quantity of dehydrated material.

EXPERIMENTAL.

Octa-3:5-diyne-2:7-diol (III; R = Me).—Methylethynylcarbinol (37 g.) in ethanol (20 c.c.) was added to a mixture of cuprous chloride (100 g.), ammonium chloride (160 g.), hydrochloric acid (1 c.c.), and water (425 c.c.) at room temperature. The temperature was raised to 55° and air was passed in for 6½ hours, a condenser containing solid carbon dioxide and alcohol being used to prevent loss of carbinol. Isolation with ether and distillation gave a mixture of stereoisomers of octa-3:5-diyne-2:7-diol (31 g.), m. p. 84–87° (change of state at 65°), b. p. ca. 120°/10⁻⁴ mm. A single process of chromatography on 2 g. of this product gave one of the stereoisomeric forms (0.3 g.), m. p. 64–67° (Lespieau, *Ann. Chim.*, 1912, 27, 137, quotes m. p. 67.5–68° for one of the isomeric forms. The other has m. p. 108–109° according to Zal'kind and Gverdtsiteli, *J. Gen. Chem. Russia*, 1939, 9, 971).

Dodeca-5:7-diyne-4:9-diol (III; R = Pr).—(a) Propylethynylcarbinol (25 g.; Bowden, Heilbron, Jones, and Weedon, *J.*, 1946, 45) in ethanol (25 c.c.) was added dropwise during 15 minutes to a solution of ammonium chloride (160 g.), cuprous chloride (100 g.), and concentrated hydrochloric acid (1.5 c.c.) in water (450 c.c.) at 50–55°. The mixture was stirred for 15 minutes at this temperature; air was then passed in for 2 hours, by which time the mixture had assumed a deep greenish colour. After cooling, the product was isolated with ether and distilled from a Claisen flask with a low, wide side-arm giving the glycol (21.2 g.), b. p. 134°/10⁻³ mm., n_D^{25} 1.5178 (Zal'kind and Gverdtsiteli, *loc. cit.*, give b. p. 159–162°/7 mm.).

(b) Propylethynylcarbinol (5 c.c.) was added to a solution of ammonium chloride (16 g.), cuprous chloride (10 g.), and concentrated hydrochloric acid (0.15 c.c.) in water (45 c.c.) during 5 minutes. With the mixture at a temperature of 50–55°, air was passed in and a further 25 c.c. of the carbinol

was added dropwise during 1 hour. After oxidation for 8 hours precipitation of cupric salts commenced. Sufficient dilute hydrochloric acid was added to the cooled mixture to dissolve the solid, and isolation with ether gave the glycol (23 g.), b. p. $133^{\circ}/10^{-3}$ mm., n_D^{20} 1.5175. One of the stereoisomeric forms of the *bis-a-naphthylurethane* was isolated from the mixture of isomers by recrystallisation from ethanol. It formed needles, m. p. 158° (Found: N, 5.05. $C_{24}H_{20}O_4N_2$ requires N, 5.25%).

Dodecane-4: 9-diol.—Dodeca-5: 7-diyne-4: 9-diol (4.85 g.) in ethyl acetate (100 c.c.) was hydrogenated in the presence of platinum oxide (10 mg.) until absorption ceased. Removal of catalyst and solvent and crystallisation of the residual solid from light petroleum (b. p. $40-60^{\circ}$) gave *dodecane-4: 9-diol* (4.5 g.) as lustrous leaflets, m. p. 53° (Found: C, 71.45; H, 12.75. $C_{12}H_{24}O_2$ requires C, 71.25; H, 12.95%).

1: 6-Diphenylhexa-2: 4-diyne-1: 6-diol (III; R = Ph).—Phenylethynylcarbinol (25 g.; Jones and McCombie, *J.*, 1942, 733) in ethanol (50 c.c.) was added to a mixture of ammonium chloride (160 g.), cuprous chloride (100 g.), concentrated hydrochloric acid (1.5 c.c.), and water (450 c.c.) at $50-55^{\circ}$. Air was passed in for 2 hours; isolation with ether and crystallisation from benzene gave a mixture of stereoisomers as leaflets (12 g.), m. p. 102° . Repeated crystallisations from benzene gave matted needles with m. p. 122° (sintered at 90° and softened at 103°) (Zal'kind and Gverdtsitel, *loc. cit.*, give m. p. $132-133^{\circ}$).

Octa-3: 5-diyne-1: 8-diol (IV; R = H).—A solution of but-1-yn-4-ol (15 g.) (Macallum, U.S.P. 2,125,384) in ethanol (25 c.c.) was added to ammonium chloride (96 g.), cuprous chloride (60 g.), and concentrated hydrochloric acid (0.9 c.c.) in water (270 c.c.) during 20 minutes. Air was passed in at $50-55^{\circ}$ for 2 hours and after the mixture had been cooled and saturated with salt the product was isolated with ether, giving *octa-3: 5-diyne-1: 8-diol* (7.1 g.), m. p. $42-43^{\circ}$, b. p. $135^{\circ}/10^{-4}$ mm. The solid became scarlet on exposure to light and air and no satisfactory analytical data could be obtained (Found: C, 68.0; H, 7.1. $C_8H_{10}O_2$ requires C, 69.5; H, 7.3%). The *diacetate* crystallised from petroleum (b. p. $80-100^{\circ}$) in needles, m. p. 63° (Found: C, 64.85; H, 6.3. $C_{12}H_{14}O_4$ requires C, 64.85; H, 6.35%). A solution of the diol (3.3 g.) in ethyl acetate (50 c.c.) was hydrogenated in the presence of platinum oxide (20 mg.) giving *octane-1: 8-diol* (3.0 g.), m. p. $60-61^{\circ}$ (from ethyl acetate) (Franke and Lieben, *Monatsh.*, 1914, 35, 1939, give m. p. 60°).

Deca-4: 6-diyne-2: 9-diol (IV; R = Me).—1-Pentyn-4-ol (25 g., Haynes and Jones, *J.*, 1946, 954) in ethanol (50 c.c.) was added to a mixture of ammonium chloride (160 g.), cuprous chloride (100 g.), concentrated hydrochloric acid (1.5 c.c.), and water (450 c.c.) at $50-55^{\circ}$ during 30 minutes. Air was then passed in for 135 minutes at $50-55^{\circ}$, and extraction of the cooled mixture with ether and distillation of the dried extract gave *deca-4: 6-diyne-2: 9-diol* (20.35 g.), b. p. $136^{\circ}/10^{-3}$ mm., n_D^{20} 1.5345. This material solidified at 0° but melted at room temperature (Found: C, 72.35; H, 8.7. $C_{10}H_{14}O_2$ requires C, 72.3; H, 8.5%). One of the stereoisomeric forms of the *bis-3: 5-dinitrobenzoate*, m. p. 192° , was isolated by fractional precipitation with petrol from an ethyl acetate solution of the mixture of isomers (Found: N, 10.0. $C_{22}H_{14}O_{12}N_4$ requires N, 10.1%).

Di-(1-hydroxycyclohexyl)butadiyne (II; $R_1R_2 = C_6H_{10}$).—3 C.c. of a solution of 1-ethynylcyclohexanol (25.2 g., Hennion and Murray, *J. Amer. Chem. Soc.*, 1942, 64, 1220) in ethanol (30 c.c.) were added to a solution of ammonium chloride (8 g.), cuprous chloride (2.5 g., 0.2 equivalent), and concentrated hydrochloric acid (0.5 c.c.) in water (25 c.c.) at 30° , and the mixture stirred for 5 minutes. The temperature was raised to 70° , air was passed in, the rest of the carbinol solution was added dropwise during $3\frac{1}{2}$ hours, and oxidation was continued for a further $4\frac{1}{2}$ hours. The mixture was poured into 300 c.c. of ammonium chloride solution and the precipitated solid completely freed from copper salts by washing it with *N*-hydrochloric acid followed by water. After being dried, this solid was recrystallised twice from benzene to give *di-(1-hydroxycyclohexyl)butadiyne* (23.5 g.), m. p. 173° (Zal'kind and Aizikovich, *J. Gen. Chem. Russia*, 1937, 7, 227, give m. p. 173°) (Found: C, 78.05; H, 8.85. Calc. for $C_{14}H_{22}O_2$: C, 78.0; H, 9.0%).

3: 8-Dimethyldeca-4: 6-diyne-3: 8-diol (II; $R_1 = Me$; $R_2 = Et$).—10 C.c. of a solution of methyl-ethynylethynylcarbinol (20.8 g.; Campbell, Campbell, and Eby, *J. Amer. Chem. Soc.*, 1938, 60, 2882) in ethanol (25 c.c.) were added to a solution of ammonium chloride (8 g.), cuprous chloride (2.5 g.), and concentrated hydrochloric acid (0.05 c.c.) in water (25 c.c.), and the mixture stirred for a minute at room temperature. The colour changed from brown to green. The temperature was raised to and maintained at $65-70^{\circ}$ whilst air was passed in at a rate of about 2 l. per minute. The remainder of the carbinol solution was added in 5 c.c. portions during the next 8 hours, and the oxidation was continued for a further 5 hours. The cooled mixture was poured into 200 c.c. of ammonium chloride solution and the resultant solid washed with dilute hydrochloric acid to give 14 g. of a solid, m. p. $80-88^{\circ}$. With 6 equivs. of cuprous ammonium chloride solution the yield is slightly better and the reaction takes only 2 hours. Solution of a portion (2 g.) in the minimum volume of ethyl acetate followed by partial precipitation with petroleum (b. p. $80-100^{\circ}$) gave one of the stereoisomeric forms (0.85 g.), m. p. 88° (I.G. Farb. F.P. 765,469 give m. p. 89°) (Found: C, 73.95; H, 9.25. Calc. for $C_{12}H_{18}O_2$: C, 74.2; H, 9.35%).

Dodeca-3: 9-diene-5: 7-diyne-2: 11-diol (V) (with F. SONDHEIMER).—Hex-3-en-5-yn-2-ol (6 g.; Heilbron, Jones, Smith, and Weedon, *J.*, 1946, 57) was slowly dropped into a stirred solution of ammonium chloride (80 g.) and cuprous chloride (50 g.) in water (200 c.c.), maintained at 55° . Air was bubbled through the red solution at this temperature for 2 hours during which time much black gum separated. The product isolated by repeated ether extraction contained much polymeric material from which it was separated by boiling with water. This furnished the *diol* (1.5 g.) as light yellow needles, m. p. 92° , which after recrystallisation from either water or benzene (nitrogen atmosphere) gave colourless needles, m. p. $94-95^{\circ}$ (Found: C, 75.5; H, 7.45. $C_{12}H_{18}O_2$ requires C, 75.75; H, 7.4%). The glycol slowly becomes yellow in air. Light absorption: see Part XIV, p. 1587.

Dodecane-2: 11-diol (with F. SONDHEIMER).—A solution of the above glycol (400 mg.) in methanol (20 c.c.) was shaken with hydrogen in the presence of platinum oxide (10 mg.) until absorption was complete. Crystallisation of the product from pentane-ether (3: 1) gave *dodecane-2: 11-diol* (350 mg.) as plates, m. p. $54-55^{\circ}$ (Found: C, 71.1; H, 12.85. $C_{12}H_{24}O_2$ requires C, 71.25; H, 12.95%). Oxid-

ation of the diol with chromic acid in sulphuric acid gave a 75% yield of dodecane-2 : 11-dione, leaflets from light petroleum (b. p. 40–60°), m. p. 67° (Cason and Prout, *J. Amer. Chem. Soc.*, 1944, **66**, 48, give m. p. 87.4–87.8°). Sebacic acid, m. p. 130–131°, undepressed on admixture with an authentic specimen (m. p. 132°), was obtained when the diketone was shaken with sodium hypobromite solution for 48 hours at 20°.

10:15-Dimethyltetracos-11:13-diyne-10:15-diol (II; $R_1 = \text{Me}$; $R_2 = \text{C}_6\text{H}_{13}$).—Methylnonylethynylcarbinol (10 g.; Locquin and Sung, *Compt. rend.*, 1922, **174**, 1427) in ethanol (10 c.c.) was added to a mixture of ammonium chloride (64 g.), cuprous chloride (40 g.), concentrated hydrochloric acid (0.4 c.c.), and water (200 c.c.), and stirred at 65–67°. Oxygen was passed through at about 3 l. per minute, and after 45 minutes the reaction mixture was cooled, hydrochloric acid was added to dissolve copper salts, and the product was isolated with ether. Distillation gave the *glycol* (2.75 g.), b. p. 210°/10–3 mm., m. p. 40–43° (Found: C, 79.9; H, 11.7. $\text{C}_{26}\text{H}_{46}\text{O}_2$ requires C, 79.95; H, 11.85%). 5.4 G. of carbinol were recovered.

The authors thank the Rockefeller Foundation and I.C.I. Ltd., Dyestuffs Division, for financial assistance, and the Department of Scientific and Industrial Research for a maintenance grant (K. H. S.). Light-absorption data were determined by Dr. E. A. Braude.

314. Researches on Acetylenic Compounds. Part XIII. The Reaction Between Epichlorohydrin and Sodium Acetylide. A Novel Route to the Ethynyl-ethylenic Alcohol, Pent-2-en-4-yn-1-ol.*

By L. J. HAYNES, SIR IAN HEILBRON, E. R. H. JONES, and F. SONDEIMER.

Condensation between epichlorohydrin and sodium acetylide in liquid ammonia gives, rather unexpectedly, the ethynyl-ethylenic primary alcohol, pentenynol (I). Evidence is adduced to show that this reaction proceeds *via* the ethynyl oxide (III); in particular, it is demonstrated that 1:2-epoxy-3-phenylpropane ($\text{Ph}\cdot\text{CH}_2\cdot\text{CH}(\text{O})\cdot\text{CH}_2$) is isomerised to cinnamyl

alcohol by treatment with sodamide in liquid ammonia. Analogous condensations with the sodio-derivatives of 1-hexyne and phenylacetylene give similar products, albeit in poorer yields.

IN connexion with the synthesis of various types of acetylenic hydroxy-acids and the derived unsaturated lactones (Haynes and Jones, *J.*, 1946, 503 and 954) the condensation of various oxides or epoxy-compounds with sodium acetylide in liquid ammonia has been investigated. This paper describes some rather unexpected results which were obtained when epichlorohydrin was employed in such reactions. There is only one instance in the literature of the reaction of epichlorohydrin with an acetylenic compound, namely phenylacetylenylmagnesium bromide (Iotsitch, *J. Russ. Phys. Chem. Soc.*, 1903, **35**, 554), when a normal addition product, either $\text{Ph}\cdot\text{C}\equiv\text{C}\cdot\text{CH}_2\cdot\text{CH}(\text{OH})\cdot\text{CH}_2\text{Cl}$ or $\text{Ph}\cdot\text{C}\equiv\text{C}\cdot\text{CH}(\text{CH}_2\text{Cl})\cdot\text{CH}_2\cdot\text{OH}$, was obtained in poor yield.

When epichlorohydrin reacts with sodium acetylide in liquid ammonia, the sole product, obtained in about 40% yield, is the ethynylethylenic alcohol, pent-2-en-4-yn-1-ol (I). This substance had already been prepared in these laboratories in extremely poor overall yield from

acetaldehyde *via* vinyl ethynylcarbinol (II) (Heilbron, Jones, Lacey, McCombie, and Raphael, *J.*, 1945, 77). The yield of the primary alcohol, based on the epichlorohydrin, is markedly dependent on the quantity of sodium acetylide employed. Thus with equimolar quantities of chlorohydrin and sodium under standard conditions, the yield is only 16%, but it is not improved beyond 40% when more than two moles of sodium to one of chlorohydrin are employed. Varying the reaction time from 5 to 18 hours has no appreciable effect upon the yield, and this was considerably reduced in an experiment in which the reaction mixture was kept under pressure at room temperature for 18 hours. When epibromohydrin is used under the optimum conditions found for the chlorohydrin, only a 25% yield of pentenynol is obtained. With sodium acetylide in liquid ammonia epi-iodohydrin yields mainly di-iodoacetylene.

The formation of pentenynol (I) from epichlorohydrin can conceivably take place by either of two routes, A and B, depending upon whether the initial reaction step is one of substitution or

* Patent application pending.

$$\begin{array}{c} \text{Route A.} \quad \text{HC}\equiv\text{CNa} + \text{Cl}\cdot\text{CH}_2\cdot\underset{\text{O}}{\text{CH}}\cdot\text{CH}_2 \cdot \rightarrow \text{HC}\equiv\text{C}\cdot\text{CH}_2\cdot\underset{\text{O}}{\text{CH}}\cdot\text{CH}_2 \quad (\text{III.}) \\ \downarrow \\ \text{HC}\equiv\text{C}\cdot\text{CH}=\text{CH}\cdot\text{CH}_2\cdot\text{OH} \quad (\text{I.}) \\ \uparrow \end{array}$$

$$\text{Route A. } \text{HC}\equiv\text{CNa} + \text{Br}\cdot\text{CH}_2\text{CH}(\text{OH})\text{CH}_3 \text{ (IV.)} \longrightarrow \text{HC}\equiv\text{C}\cdot\text{CH}=\text{CH}\cdot\text{CH}(\text{OH})\cdot\text{CH}_3 \text{ (V.)}$$

$$(VI.) \quad \text{Ph} \cdot \text{CH}_2 \cdot \underset{\text{O}}{\text{CH} - \text{CH}_2} \longrightarrow \text{Ph} \cdot \text{C} \equiv \text{HCH} \cdot \text{CH}_2 \cdot \text{OH}$$

Attempts to extend the scope of the novel reaction between epichlorohydrin and sodium acetylide, by using substituted acetylenes, have not been particularly successful. Thus phenylacetylene gives only a 15% yield of the primary alcohol (5-phenylpent-2-en-4-yn-1-ol) (VII), the structure of which is confirmed by the ultra-violet absorption data and by

EXPERIMENTAL.

Pent-2-en-4-yn-1-ol (I).—(a) To a solution of sodium acetylide in liquid ammonia (7 l.), prepared from sodium (276 g.), using the ferric nitrate catalyst of Vaughn, Vogt, and Nieuwland (*J. Amer. Chem. Soc.*, 1934, **56**, 2120) to catalyse the formation of sodamide, epichlorohydrin (555 g.) was run in during 2 hours with stirring and cooling (alcohol-carbon dioxide). Nitrogen was introduced during the addition and during the subsequent 16 hours' stirring after which ammonium chloride (660 g.) was added during 2½ hours and the ammonia evaporated on the steam-bath. Ether (3 l.) was added, and the solid residue obtained on filtering was dissolved in water. A small quantity of tar was removed by filtration, the solution was extracted thoroughly with ether, and the combined ethereal solutions were washed with dilute sulphuric acid and water and then dried. Evaporation of the solvent and distillation gave pent-2-en-4-yn-1-ol (201 g.), b. p. 71–73°/19 mm., n_D^{20} 1.4972. Light absorption: Maximum, 2230 Å.; ϵ = 15,000. Infrared, 2290 Å.; ϵ = 10,000 (Heilbron, Jones, Lacey, McCombie, and Raphael, *J.*, 1945, 77, give b. p. 90°/50 mm., n_D^{20} 1.4933; maximum, 2230 Å.; ϵ = 14,000). The α -naphthylurethane had m. p. 111–112°, undepressed on admixture with an authentic specimen (m. p. 110–111°).

(b) The method described above using epibromohydrin (137 g.) and sodium (46 g.) in liquid ammonia (1.2 l.) gave: (i) Pent-2-en-4-yn-1-ol (21 g.), b. p. 80–81°/27 mm., n_D^{20} 1.4963, and (ii) a colourless liquid (10.6 g.), b. p. 74–75°/1.5 mm., n_D^{20} 1.4831, analysing for $C_{10}H_{14}O_2$ (Found: C, 66.75, 66.4; H, 6.7, 6.7. $C_{10}H_{14}O_2$ requires C, 66.65; H, 6.7%). Light absorption: Maximum, 2230 Å.; ϵ = 16,000. Inflexion, 2310 Å.; ϵ = 12,500. The structure of this product has not yet been ascertained.

Hex-3-en-5-yn-2-ol (V).—The method described above using 1-bromo-2:3-epoxybutane (77.5 g.; Delaby, *Compt. rend.*, 1923, 176, 589) and sodium (24 g.) in liquid ammonia (600 c.c.) gave hex-3-en-5-yn-2-ol (21.3 g.), b. p. 82–84°/32 mm., n_D^{20} 1.4860 (Heilbron, Jones, Smith, and Weedon, *J.*, 1946, 54, give b. p. 79–81°/30 mm., n_D^{20} 1.4842). The phenylurethane had m. p. 83°, undepressed on admixture with an authentic specimen, m. p. 83–84° (Jones and McCombie, *J.*, 1943, 261). The α -naphthylurethane separated from light petroleum (b. p. 60–80°) in clusters of needles, m. p. 83–84°, undepressed on admixture with a specimen prepared from authentic material (Found: N, 5.35. $C_{17}H_{18}O_2N$ requires 5.3%).

As a by-product of this experiment there was obtained a substance (7.5 g.), b. p. 122–124°/32 mm., 66–67°/0.5 mm., n_D^{20} 1.4745, believed to be 2-(2:3-epoxy-1-butoxy)hex-3-en-5-yne, a colourless pleasant-smelling liquid, slowly turning yellow in air (Found: C, 71.85; H, 8.6. $C_{10}H_{14}O_2$ requires C, 72.25; H, 8.5%). Light absorption: Maximum, 2230 Å.; ϵ = 13,500. Inflexion, 2280 Å.; ϵ = 12,500. Active hydrogen (Zerewitinoff): The ether (94 mg.) evolved 12.7 c.c. of methane (after heating to 90°) at 20°/772 mm. (0.95 active hydrogen atom). Hydrogenation of the ether (2.06 g.) in ethyl acetate (50 c.c.) in the presence of platinum oxide (10 mg.) (914 c.c. hydrogen absorbed at 13°/760 mm., equivalent to 3.05) gave 2-(2:3-epoxy-1-butoxy)hexane (1.5 g.), b. p. 86–88°/16 mm., n_D^{20} 1.4265 (Found: C, 69.45; H, 12.0. $C_{10}H_{20}O_2$ requires C, 69.7; H, 11.7%). This saturated ether gave a negligible volume of methane in an active hydrogen determination.

Cinnamyl Alcohol.—To sodamide, prepared from sodium (1.75 g.), in liquid ammonia (100 c.c.) was added 1:2-epoxy-3-phenylpropane (10 g.; Levy and Sfras, *Bull. Soc. chim.*, 1931, 49, 1823). After 20 hours' stirring in nitrogen, ammonium chloride (5 g.) was added, and the product was isolated with ether in the usual way. Distillation gave cinnamyl alcohol (7.8 g.), b. p. 85–87°/0.05 mm., n_D^{20} 1.5852, which rapidly solidified. After one crystallisation from ether-pentane it had m. p. 33°, not depressed on admixture with an authentic specimen (m. p. 33°). Only a 50% yield of the alcohol was obtained when the reaction time was reduced to 6 hours.

5-Phenylpent-2-en-4-yn-1-ol (VII).—To sodamide, prepared from sodium (7.7 g.) in liquid ammonia (400 c.c.) as described above, phenylacetylene (35 g.) was added during 15 minutes. After 1 hour's stirring, epichlorohydrin (30.6 g.) was run in during 15 minutes, the solution was stirred for a further 16 hours, and was then worked up in the usual manner. Distillation gave, besides some starting material, two fractions: (i) B. p. 70–72°/1 mm., n_D^{20} 1.5459 (1.8 g.); (ii) *5-phenylpent-2-en-4-yn-1-ol* (6.8 g.) as a pale yellow oil, turning dark yellow on keeping, b. p. 94–96°/10⁻³ mm., n_D^{20} 1.6173 (Found: C, 83.0; H, 6.45. $C_{11}H_{14}O$ requires C, 83.5; H, 6.35%). There was a considerable resinous residue. Light absorption: Maxima, 2590, 2720, 2890 Å.; ϵ = 19,000, 26,000, and 21,000 respectively. The α -naphthylurethane separated from petroleum (b. p. 80–100°) in plates, m. p. 132° (Found: N, 4.25. $C_{23}H_{17}O_2N$ requires N, 4.3%).

5-Phenylpentan-1-ol and 8-Phenylvaleric Acid.—A solution of the above carbinol (1 g.) in ethyl acetate (30 c.c.) was shaken with hydrogen in the presence of platinum oxide (10 mg.) until absorption was complete. Removal of catalyst and solvent, gave on distillation *5-phenylpentan-1-ol* (0.75 g.), b. p. 150–151°/18 mm., n_D^{20} 1.5170 (v. Braun, *Ber.*, 1911, 44, 2867, gives b. p. 155°/20 mm.). Oxidation of the saturated carbinol (0.6 g.) with chromic acid in the usual way gave *8-phenylvaleric acid* (0.4 g.) which after crystallisation from water had m. p. 57.5° (Staudinger and Müller, *Ber.*, 1923, 56, 713, give m. p. 57°).

Non-2-en-4-yn-1-ol (VIII).—1-Hexyne (80 g.) was caused to react with sodamide, made from sodium (23.5 g.) in liquid ammonia (1 l.), as previously described, but instead of being cooled, the reaction flask was well lagged with cork dust. Epichlorohydrin (80 g.) was dropped in during 1 hour, then the solution was stirred for 42 hours without cooling, the volume being kept constant by adding more liquid ammonia occasionally. On working up in the usual manner, distilling off starting materials, and carefully fractionating the residue through a Widmer column, there was obtained *non-2-en-4-yn-1-ol* (24 g.) as a pleasant-smelling colourless oil, b. p. 67°/0.1 mm., n_D^{20} 1.4920 (Found: C, 77.5; H, 10.5. $C_9H_{14}O$ requires C, 78.2; H, 10.2%). Light absorption: Maxima, 2280, 2370 Å.; ϵ = 14,000 and 12,000 respectively. The α -naphthylurethane separated from light petroleum (b. p. 40–60°) as a microcrystalline powder, m. p. 69° (Found: N, 4.75. $C_{20}H_{14}O_2N$ requires N, 4.55%). In an experiment in which exactly the same conditions were employed as for the condensation with sodium acetylide (*viz.*, hexyne: epichlorohydrin = 2:1, reaction time 20 hours, cooling in alcohol-carbon dioxide), no appreciable amount of non-2-en-4-yn-1-ol could be detected.

n-Nonyl Alcohol.—Non-2-en-4-yn-1-ol (1.08 g.) in ethyl acetate (30 c.c.) was shaken in hydrogen with platinum oxide until absorption was complete. Removal of catalyst and solvent gave *n-nonyl alcohol* (0.8 g.), b. p. 115°/22 mm., n_D^{20} 1.4355; the *p*-nitrophenylurethane had m. p. 106°; the α -naphthylurethane had m. p. 64° (Ellis and Reid, *J. Amer. Chem. Soc.*, 1932, 54, 1674, give b. p. 213.5°, n_D^{20} 1.4320. Hoppenbrouwers, *Rec. Trav. chim.*, 1932, 51, 951, gives m. p. 104° for the *p*-nitrophenylurethane. Adamson and Kenner, *J.*, 1934, 838, give m. p. 65.5° for the α -naphthylurethane.)

The authors thank the Rockefeller Foundation for financial assistance and the University of London for Post-graduate studentships (L. J. H. and F. S.). They are indebted to Dr. E. A. Braude for the light-absorption data.

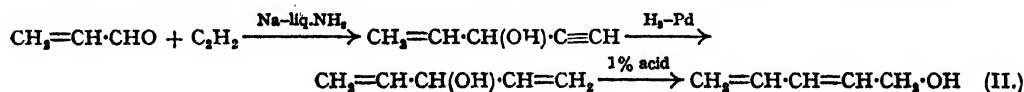

315. Researches on Acetylenic Compounds. Part XIV. A Study of the Reactions of the Readily Available Ethynyl-ethylenic Alcohol, Pent-2-en-4-yn-1-ol.

By SIR IAN HEILBRON, E. R. H. JONES, and F. SONDHEIMER.

A variety of reactions of pentenynol, illustrated in the accompanying diagram, has been studied. These include partial hydrogenation, carboxylation, hydration to methylfuran, condensation with formaldehyde to the C_8 glycol, oxidative coupling to the C_{10} glycol, and oxidation to the corresponding carboxylic acid with chromic acid. Light-absorption data for the diacetylene system in extended chromophores are quoted and discussed.

THE route hitherto available (Heilbron, Jones, Lacey, McCombie, and Raphael, *J.*, 1945, 77) to the ethynylethylenic alcohol, pent-2-en-4-yn-1-ol (I), was extremely unsatisfactory, only about a 4% yield based on acraldehyde being achieved. Now that this interesting substance can be obtained in quantity in a single-stage preparation from easily available starting materials, as described in the preceding paper, a study of some of its many reaction possibilities became worth while.

In the first place its partial hydrogenation to pentadienol (II) was investigated. This substance, which had been found to give an elastic polymer, had previously been prepared (Heilbron, Jones, McCombie, and Weedon, *J.*, 1945, 84) in only very poor yield (*ca.* 5% based on acraldehyde) by the route indicated in the accompanying formulæ. A direct preparation from pentenynol (I) offered the possibility of obtaining reasonable samples of this material

for more detailed polymerisation studies. Partial hydrogenation using a palladium-calcium carbonate catalyst proceeded in a manner similar to that already observed (Heilbron, Jones, McCombie, and Weedon, *loc. cit.*) with the homologous hexenynol, and after careful fractionation a 50% yield of the dienol (II) was obtained.

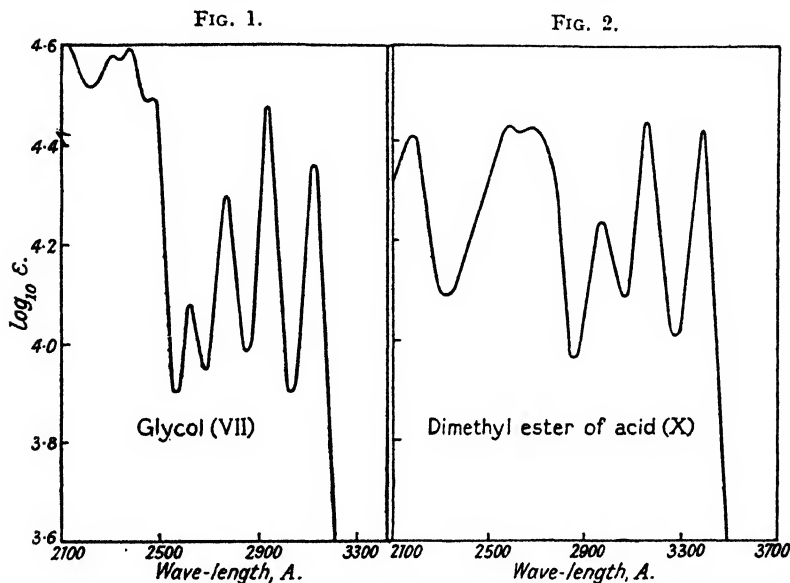

Carboxylation of the Grignard complex (*cf.* Haynes and Jones, *J.*, 1946, 503) gave the *hydroxy-acid* (III), exhibiting the expected light-absorption properties and converted into ϵ -hydroxyhexoic acid on complete hydrogenation. Hydration of pentenynol with sulphuric acid and mercuric sulphate proceeded analogously to that of the homologous hexenynol (Heilbron, Jones, Smith, and Weedon, *J.*, 1946, 54) and yielded 35% of 2-methylfuran (IV); the yield of this highly volatile material could almost certainly be improved by more detailed attention to the reaction conditions, etc.

When pentenynol was originally obtained (*J.*, 1945, 77) one of the few reactions carried out with it involved the condensation of its Grignard complex with butaldehyde to give an ethylenic-acetylenic glycol. Attempts to condense formaldehyde with pentenynol in the same manner were not successful, but by using a copper hydroxide catalyst (General Aniline and Film Corp., U.S.P. 2,238,471) and an aqueous solution of formaldehyde, the *diol* (V) was obtained in 40% yield. Its light-absorption properties were as expected for the structure (V) and this was conclusively proved by hydrogenation to hexane-1:6-diol. The Mannich condensation of pentenynol with formaldehyde and diethylamine, to give the amino-alcohol (VI), has already been described in Part XI (p. 1578).

In Part XII of this series (p. 1580), in which the scope of the oxidative coupling of ethynyl-carbinols to diacetylenic glycols in the presence of cuprous ammonium chloride has been considerably extended, the employment of the ethynyl-ethylenic alcohol, hex-3-en-5-yn-2-ol, in such reactions was described. Pentenynol also can readily be oxidised by air in cuprous salt solution giving a good yield of the *glycol* (VII), hydrogenated to decane-1:10-diol. The light-absorption curve for this glycol is given in Fig. 1, and in the Table the data are compared with those for its homologue, the preparation of which from hexenynol is described in Part XII. It will be noted that the locations of the longer wave-length bands (2930 and 3120 Å.) of both glycols approximate very closely to those recorded for decatetraenol, containing four conjugated ethylenic linkages. Therefore, although conjugated diacetylenes, unlike the vinyl-acetylenes and dienes, fail to show high intensity absorption in the ultra-violet (see Part XII), when the diacetylene grouping becomes part of a larger chromophore, as in glycols such as (VII), it appears to be capable of transmitting electronic vibrations, giving rise to absorption

corresponding to fully conjugated systems. As in all other cases where acetylenic bonds are involved in chromophoric systems, considerable intensity reductions are observed. The multiplicity of shorter wave-length bands indicates a marked tendency of the diacetylene grouping to participate in partial chromophores, probably of the en-yne and ene-diyne types.

Oxidation of pentenynol in acetone solution with chromic acid (cf. Bowden, Heilbron, Jones, and Weedon, *J.*, 1946, 39) gives a 60% yield of the corresponding acid (VIII) which,

³ Haynes and Jones, *J.*, 1946, 503.

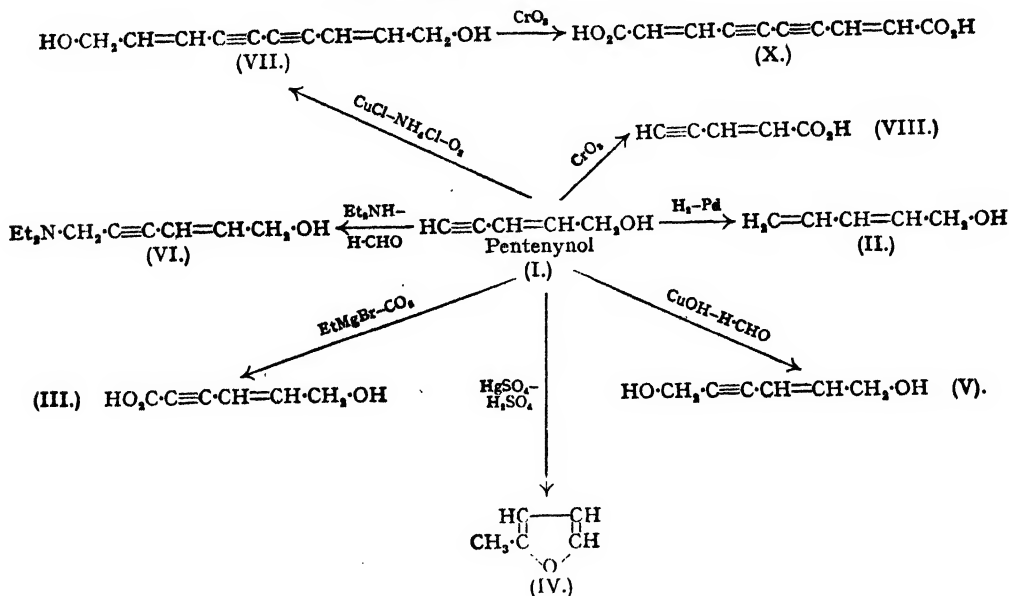

though stable in ether solution, rapidly polymerises when pure even in a vacuum in the dark. This instability may be due to the facile occurrence of an intramolecular hydration, leading to

the formation of the unsaturated lactone (IX), which would be expected to polymerise easily. Such a hypothesis is all the more convincing, since the *methyl* ester is comparatively stable. The structure of the acid is confirmed by hydrogenation to valeric acid and by the light-absorption data for the acid and its ester (Table) which are somewhat similar (although, of

course, lower in intensity) to that of sorbic acid. The glycol (VII) when oxidised under similar conditions with chromic acid gives the amorphous *di-acid* (X) purified through its crystalline *dimethyl ester*, proof of structure being obtained by hydrogenation to sebacic acid. Light-absorption data for the ester (see Fig. 2 and Table) again indicate the participation of the diacetylene group in an extended conjugated system.

Reactions of Pent-2-en-4-yn-1-ol.

EXPERIMENTAL.

(Light-absorption data determined in alcohol solutions.)

Penta-2:4-dien-1-ol (II).—A solution of pent-2-en-4-yn-1-ol (160 g.) in ethyl acetate (400 c.c.) was hydrogenated using a palladium–calcium carbonate catalyst (20 g.; 0.3% Pd) until 46.7 l. of gas had been absorbed. The product obtained after removal of catalyst and solvent was carefully fractionated through a column containing a 50 × 1.5 cm. section packed with single turn glass helices. The numerous fractions collected were divided into two portions: (i) B. p. 32–34°/1.5 mm. (34 g.), n_D^{18} 1.4620–1.4730. (ii) *Penta-2:4-dien-1-ol* (82.5 g.), b. p. 34–40°/1.5 mm., n_D^{18} 1.4770–1.4893. There was a considerable resinous residue. Light absorption: Maximum, 2230 Å., ϵ = 26,000. (Heilbron *et al.*, *J.*, 1945, 87, give b. p. 95–97°/100 mm., n_D^{18} 1.4902. Maximum, 2230 Å., ϵ = 25,000.) The various fractions composing portion (ii) differed but slightly in their light-absorption intensities; the refractive index variations are doubtless due to the presence of geometrical isomerides.

A warm solution of the pentadienol (0.4 g.) and maleic anhydride (0.5 g.) in benzene (4 c.c.) was set aside at 20° overnight. Recrystallisation of the separated solid from water gave the lactonic acid (0.48 g.), m. p. 176° (Heilbron *et al.*, *loc. cit.*, give m. p. 175–176°) undepressed on admixture with an authentic specimen.

Pent-3-en-1-yn-5-ol-1-carboxylic Acid (III).—Benzene (200 c.c.) was gradually added to a solution of ethylmagnesium bromide (from 12.5 g. magnesium) in ether (250 c.c.) at the same time as the latter was distilled off. When the temperature of the issuing vapours reached 70°, the mixture was cooled (ice) and pent-2-en-4-yn-1-ol (20.5 g.) was added during $\frac{1}{2}$ hour. After refluxing for $1\frac{1}{2}$ hours, the suspension of a fine white powder was shaken in an autoclave with solid carbon dioxide (500 g.) for 22 hours at 20°. The complex was decomposed with ice and dilute sulphuric acid and the aqueous layer was continuously extracted with ether during 24 hours. The combined extracts were washed with sodium bicarbonate solution, and from the ether layer pent-2-en-4-yn-1-ol (12.8 g.) was recovered. The bicarbonate extract was acidified and continuously extracted with ether for 48 hours. The product so obtained was crystallised from benzene–ethyl acetate (4:1) giving the *acid* (6.2 g.) as a micro-crystalline powder, m. p. 135–136°, which after subliming at 90° (bath temp.)/10^{–4} mm. and crystallisation from the same solvents formed plates, m. p. 137° (Found: C, 57.3; H, 5.05. $\text{C}_8\text{H}_8\text{O}_2$ requires C, 57.15; H, 4.8%). The *S-benzylisothiuronium* salt separated from ethyl acetate–ethanol (4:1) in plates, m. p. 155–156° (decomp.) (Found: N, 9.55. $\text{C}_{14}\text{H}_{18}\text{O}_2\text{N}_2\text{S}$ requires N, 9.6%).

A solution of the acid (1.9 g.) in methanol (30 c.c.) was hydrogenated using platinum oxide (10 mg.) as catalyst. The crude ϵ -hydroxyhexoic acid (1.8 g.) was converted into the lactone by heating it at 160° for 5 minutes, and the lactone was then heated for 3 hours with hydrazine hydrate on the steam-

bath. The hydrazide of α -hydroxyhexoic acid crystallised from ethyl acetate-methanol (6:1) in plates, m. p. 115° (Natta, Hill, and Carothers, *J. Amer. Chem. Soc.*, 1934, **56**, 456, give m. p. 114–115°).

2-Methylfuran (IV).—A mixture of pent-2-en-4-yn-1-ol (8 g.), sulphuric acid (40 c.c., 0.5% w/v), and mercuric sulphate (0.2 g.) was distilled in steam until the distillate was no longer cloudy (about 50 c.c. in $\frac{1}{2}$ hour). The distillate was saturated with salt, the upper layer separated and dried (CaCl_2), and distillation gave 2-methylfuran (2.6 g.), b. p. 64°/769 mm., n_D^{20} 1.4342 (Kizhner, *J. Gen. Chem. Russia*, 1931, **1**, 1212, gives b. p. 64°/749 mm., n_D^{20} 1.4365).

The furan (0.25 g.) was added to a warm solution of maleic anhydride (0.3 g.) in benzene (1 c.c.). After $\frac{1}{2}$ hour, the solvent was evaporated, and the residue was recrystallised from ether to give the adduct (0.4 g.) as needles, m. p. 81° (Rinckes, *Rec. Trav. chim.*, 1931, **50**, 1127, gives m. p. 80°).

Hex-2-en-4-yne-1:6-diol (V).—A copper hydroxide catalyst was made by precipitating a solution of cuprous chloride (3 g.) in hydrochloric acid (45 c.c., 12%) with potassium hydroxide solution (45 c.c., 40%); it was filtered off and washed well with water. The wet catalyst was then stirred with pent-2-en-4-yn-1-ol (15 g.), formaldehyde solution (20 g.; 40% w/v), water (6 c.c.), and calcium carbonate (0.2 g.) under reflux for 42 hours at 90° in nitrogen. The catalyst was filtered off, and distillation gave some starting material (2 g.) and a viscous liquid (7.9 g.), b. p. 120–130°/10⁻³ mm., n_D^{20} 1.5442. This rapidly solidified and after crystallisation from benzene-ethyl acetate (6:1) furnished the glycol (6.8 g.) as needles, m. p. 58–59° (Found: C, 64.1; H, 6.9. $\text{C}_8\text{H}_{12}\text{O}_4$ requires C, 64.25; H, 7.2%). Light absorption: Maximum, 2270 Å.; ϵ = 15,000. Inflection, 2370 Å.; ϵ = 12,000. The bisphenylurethane crystallised from ethanol in needles, m. p. 157° (Found: N, 8.0. $\text{C}_{20}\text{H}_{18}\text{O}_4\text{N}_2$ requires N, 8.0%).

Hexane-1:6-diol.—A solution of the above glycol (1 g.) in methanol (40 c.c.) was hydrogenated using platonic oxide catalyst (10 mg.). The product distilled at 147–148°/18 mm. as a viscous oil which rapidly solidified, and crystallisation from ether gave hexane-1:6-diol (0.6 g.), m. p. 41–42° (Hamonet, *Bull. Soc. chim.*, 1905, **33**, 539, gives b. p. 152°/17 mm., m. p. 42°). The bisphenylurethane formed needles, m. p. 170°, from ethanol (Hamonet, *loc. cit.*, gives m. p. 171–172°).

Deca-2:8-diene-4:6-diyne-1:10-diol (VII).—Pent-2-en-4-yn-1-ol (34 g.) was added during 10 minutes to a stirred solution of ammonium chloride (240 g.) and cuprous chloride (150 g.) in water (600 c.c.) at 55°. Air was then bubbled through the red solution (at 55°) for 2½ hours, and the product was isolated by repeated ethereal extraction. Crystallisation from water gave the diol (22 g.) as yellow plates, sintering at 130°, m. p. 153–155° (decomp.) which, on further crystallisation from the same solvent or from benzene (in an atmosphere of nitrogen), formed colourless plates, m. p. 155–156° (decomp.) (Found: C, 74.25; H, 6.05. $\text{C}_{10}\text{H}_{16}\text{O}_4$ requires C, 74.05; H, 6.2%). The glycol develops a brown colour in air or light. The dibenzoate, prepared with benzoyl chloride in pyridine at 20° overnight, separated from light petroleum (b. p. 80–100°) in needles, m. p. 96° (Found: C, 77.4; H, 5.0. $\text{C}_{24}\text{H}_{28}\text{O}_6$ requires C, 77.8; H, 4.9%). Light absorption: Maxima, 2340, 2640, 2810, 2950, 3150 Å.; ϵ = 63,000, 12,000, 22,000, 26,000, and 23,500 respectively.

In smaller scale experiments, in which the proportion of copper salt to carbinol was increased still further, yields up to 72% were obtained.

Hydrogenation of the glycol (0.49 g.) in methanol (40 c.c.) with platonic oxide (5 mg.) and crystallisation of the product from benzene gave decane-1:10-diol (0.31 g.) as a microcrystalline powder, m. p. 71–71.5° (Folkers and Adkins, *J. Amer. Chem. Soc.*, 1932, **54**, 1146, give m. p. 70.8–71.8°; Manske, *Org. Synth.*, Coll. Vol. II, 154, gives m. p. 72–74°).

But-1-en-3-yne-1-carboxylic Acid (VIII).—A mixture of chromium trioxide (35 g.) and concentrated sulphuric acid (56 g.) was made up to 175 c.c. with water, and this solution was added, with constant shaking during 30 minutes, to a cooled solution of pent-2-en-4-yn-1-ol (20.5 g.) in acetone (150 c.c.), the temperature being kept at 15°. After being shaken for a further 1½ hours, the mixture was poured into water and repeatedly extracted with ether. The acidic material was removed by extraction with sodium bicarbonate solution, which after acidification and ether extraction furnished but-1-en-3-yne-1-carboxylic acid (14.1 g.) as a light yellow crystalline mass, m. p. 92–93°; crystallisation from light petroleum (b. p. 80–100°) gave long colourless needles, m. p. 94°. The acid soon forms an acetone insoluble polymer, even when sealed up in a vacuum in the dark (Found: C, 62.55; H, 4.5. $\text{C}_6\text{H}_6\text{O}_2$ requires C, 62.5; H, 4.2%). The S-benzylisothiuronium salt separated from ethyl acetate in plates, m. p. 172–173° (Found: N, 10.9. $\text{C}_{13}\text{H}_{14}\text{O}_2\text{N}_2\text{S}$ requires N, 10.7%). The acid (10 g.) was refluxed for 16 hours with methyl-alcoholic sulphuric acid (2%; 200 c.c.); isolation by the usual procedure gave, besides some high boiling material, methyl but-1-en-3-yne-1-carboxylate (5.35 g.) as a pleasant smelling oil, b. p. 59°/34 mm., n_D^{20} 1.4820. On ice cooling it solidified to plates, m. p. 19–20° (Found: C, 65.7; H, 5.85. $\text{C}_6\text{H}_6\text{O}_2$ requires C, 65.45; H, 5.5%). A solution of the acid (0.65 g.) in ethyl acetate (30 c.c.) was shaken with hydrogen in the presence of platonic oxide until absorption was complete. The crude valeric acid (0.6 g.) was converted into the amide in the usual way, to give the latter as leaflets, m. p. 104–105° (Robertson, *J.*, 1919, 1220, gives m. p. 106°).

Octa-1:7-diene-3:5-diyne-1:8-dicarboxylic Acid (X).—A mixture of chromium trioxide (13 g.) and concentrated sulphuric acid (20.8 g.) was made up to 65 c.c. with water, and this solution was added, with constant shaking, to a cooled solution of deca-2:8-dien-4:6-diyne-1:10-diol (4 g.) in acetone (75 c.c.) at such a rate as to keep the temperature at 25°. The solution was shaken for a further hour, then poured into water and repeatedly extracted with ether. The acidic material was removed by shaking with sodium bicarbonate solution, which after acidification and ether extraction gave octa-1:7-dien-3:5-diyne-1:8-dicarboxylic acid (1.7 g.) as a yellow amorphous powder, charring at ca. 300°, which after several precipitations from aqueous methyl alcohol was pale yellow but still non-crystalline.

The diacid (1.6 g.) was refluxed with methyl-alcoholic sulphuric acid (1.5%; 70 c.c.) for 14 hours. On cooling, a mass of straw-coloured plates separated, and were filtered off; the filtrate was poured into water, and excess of sodium bicarbonate solution was added. Ether extraction and crystallisation of the resulting solid from methyl alcohol gave, when mixed with the solid obtained before, dimethyl octa-1:7-dien-3:5-diyne-1:8-dicarboxylate (1.35 g.) as straw-coloured plates, m. p. 103–104°. On

further recrystallisation from the same solvent, it was obtained as light yellow plates, m. p. 106° , which gradually develop a brown colour (Found: C, 66.3; H, 4.7. $C_{13}H_{10}O_4$ requires C, 66.05; H, 4.65%).

The diacid was regenerated by keeping a solution of the ester (0.3 g.) in methyl alcohol (125 c.c.) containing potassium hydroxide (4 g.) for 48 hours at room temperature. Most of the solvent was evaporated, water was added, and the acid product, isolated from the acidified reaction mixture with ether, gave the diacid (0.21 g.) having the same properties as before (Found: C, 63.85, 63.6; H, 3.9, 4.05. $C_{10}H_8O_4$ requires C, 63.15; H, 3.2%). Light absorption: Maxima, 2580, 2650, 2955, 3155, 3375 μ ; $\epsilon = 28,500, 28,500, 17,500, 28,500$, and $28,500$ respectively.

Sebacic Acid.—The di-ester (130 mg.) in methyl alcohol (75 c.c.) was shaken with hydrogen in the presence of platinum oxide (10 mg.) until absorption was complete. The solution was refluxed for $1\frac{1}{2}$ hours with potassium hydroxide (2 g.), and working up in the usual way gave sebacic acid (70 mg.), m. p. 132° , undepressed on admixture with an authentic specimen (m. p. $131-132^{\circ}$).

The authors thank the Rockefeller Foundation for financial assistance, and one of them (F. S.) is indebted to the University of London for a Post-graduate Studentship. Light-absorption data were determined by Dr. E. A. Braude.

316. Some Organic Derivatives of Hexachlorodisiloxane.

By H. J. EMELÉUS and D. S. PAYNE.

Methyl, ethyl, and phenyl derivatives of hexachlorodisiloxane have been prepared by reaction of the oxychloride with the corresponding Grignard reagent in ethereal solution. Hydrolysis of monochloropentaethylidisiloxane gave a stable monomeric hydroxy-compound.

DESPITE the preparation of a large number of organic monosilicon chlorides by Kipping and his co-workers and others, no attempt has been made to prepare organic silicon oxychlorides. In view of the predominance of the Si-O-Si linkage in the "silicone" polymers, it was of interest to prepare certain simple organic silicon oxychlorides and to examine their properties. In this paper the reactions between hexachlorodisiloxane, the simplest silicon oxychloride known, and methylmagnesium chloride and ethyl- and phenyl-magnesium bromides are described. The mono-, di-, tri-, tetra-, and penta-ethyl and the dimethyl and diphenyl derivatives of the oxychloride have been isolated.

All the organodisiloxane *chlorides* isolated were colourless mobile liquids with melting points below room temperature, which hydrolysed readily with water. The products of hydrolysis from Si_2OCl_2Et , $Si_2OCl_2Et_2$, $Si_2OCl_2Me_2$, and $Si_2OCl_2Ph_2$ were white solids, whilst $Si_2OCl_2Et_3$ gave a translucent viscous liquid, which polymerised further on standing to a rubber-like solid. The products obtained by the hydrolysis of $Si_2OCl_2Et_4$ and Si_2OClEt_5 were liquids which were readily soluble in ether. From the products of hydrolysis of Si_2OClEt_5 it was possible to isolate in theoretical yield a monohydroxy-derivative, which was a stable liquid with a smell reminiscent of that of camphor. These hydrolysis experiments, which were qualitative, indicated a small decrease in the ease of hydrolysis as the number of substituent organic groups was increased.

The action upon diethyltetrachlorodisiloxane of ammonium fluoride or potassium hydrogen difluoride led to formation of ethylsilicon trifluoride, which was fully characterised, together with a residue of polymerised material. This result, which illustrates the instability of the Si-O-Si bond to fluorination, is in agreement with recent work by Booth and Osten (*J. Amer. Chem. Soc.*, 1945, **67**, 1092), who obtained a large yield of silicon tetrafluoride in the reaction between hexachlorodisiloxane and antimony trifluoride. The same point has been demonstrated by Emeléus and Wilkins, who prepared ethylsilicon trifluoride by the action of sulphuric acid on a mixture of ethylsilicic acid and calcium fluoride (*J.*, 1944, 454). Experiments on the fluorination of the other alkyl and aryl derivatives described in this paper have not so far been made, but some at least might be expected to yield stable fluoro-derivatives.

The photochemical chlorination of tetrachlorodiethylidisiloxane gave a theoretical yield of the fully chlorinated derivative. Thermal chlorination of the same compound at $150-200^{\circ}$ resulted in the formation of a small quantity of hexachloroethane, indicating that some fission of the Si-C bond had occurred. The action of alkali on the fully chlorinated material from the photochemical reaction leads to fission of the C-Si bond and the subsequent formation of tetrachloroethylene, obtained from the initial hydrolysis product, pentachloroethane, by loss of hydrogen chloride. This is in agreement with the known reaction of chloroalkylmonosilicon chlorides with alkali.

Structural isomerism should be possible in the di-, tri-, and tetra-substituted derivatives of

hexachlorodisiloxane. This point has not been fully studied, but in the case of the diethyl derivative; $\text{Si}_2\text{OCl}_4\text{Et}_2$, the action of ammonium fluoride yields only ethylsilicon trifluoride, which indicates that one ethyl group is attached to each silicon atom. No fission of the C-Si bond was observed during this reaction. The preparation of hexa-alkyl- and -aryl-disiloxanes was attempted by Schumb, Ackerman, and Saffer (*J. Amer. Chem. Soc.*, 1938, **60**, 2486) by applying the Wurtz reaction to hexachlorodisiloxane and the alkyl or aryl halides. These experiments yielded, however, only the fully substituted monosilicon derivatives in good yield. Using the Grignard reaction with phenylmagnesium bromide, Schumb and Saffer (*ibid.*, 1939, **61**, 363) obtained a 40% yield of hexaphenyldisiloxane. The corresponding reaction using hexabromodisiloxane yielded small amounts of the monosilicon derivative, triphenylsiliconal. In the experiments described here no products of low molecular weight corresponding to monosilicon derivatives were detected. Yields of the desired products were relatively high, but in every case a residue consisting of material of high molecular weight was obtained.

EXPERIMENTAL.

Analysis.—The determination of the percentage of chlorine and silicon present in the compounds obtained was carried out by Gillian, Liebhopsky, and Wimslow's method (*J. Amer. Chem. Soc.*, 1941, **63**, 801). Owing to the low volatility of the derivatives of Si_2OCl_4 it was possible to weigh the sample out in a small gelatin ampoule and then to bring it into reaction with A.R. sodium peroxide in a Parr microbomb. The quantity of sample weighed out varied with the percentage of chlorine in the compounds under analysis, from about 90 mg. of $\text{Si}_2\text{OCl}_4\text{Et}$ to about 150 mg. of $\text{Si}_2\text{OCl}_4\text{Et}_2$.

Hexachlorodisiloxane.—Four methods were investigated for this preparation: (i) the reaction between a chlorine-oxygen mixture and elemental silicon at temperatures between 700° and 800°; (ii) the reaction between silicon tetrachloride and oxygen at 900–950°; (iii) the oxidation of silicochloroform by means of solid oxidising agents at temperatures from 200° to 400°; (iv) the partial hydrolysis of silicon tetrachloride in ethereal solution. Method (iii) resulted mainly in the complete oxidation of the silico-chloroform, leading to formation of silicon and hydrogen chloride. Small yields of Si_2OCl_4 were obtained by method (iv), but the main portion of the products consisted of higher oxychlorides. Methods (i) and (ii) gave results which were suitable for the preparation of Si_2OCl_4 in large quantities. The reaction between silicon tetrachloride and oxygen had the additional merit of being capable of adaptation for use as a continuous process. Dry oxygen was passed at the rate of 2–4 l./hr. through silicon tetrachloride kept about 10° below its b. p. The mixture of silicon tetrachloride and oxygen thus produced passed through the furnace tube maintained at 900–950°. The products together with excess of silicon tetrachloride were condensed by means of two water-cooled, double-surface condensers, and the condensed liquid was returned to the silicon tetrachloride boiler. The b. p. of the silicon tetrachloride increased as the experiment proceeded, and after 2–5 days the apparatus was shut down and the silicon tetrachloride fractionated. Hexachlorodisiloxane, b. p. 137–138°, was collected. A small residue of higher oxychlorides was obtained.

The Reaction of Hexachlorodisiloxane with a Grignard Reagent.—In all the experiments the same general method was employed. Variations in the reaction conditions are noted in the separate details of each experiment. The Grignard reagent was prepared from the organic halide by the usual method. A solution of the chloro-compound in anhydrous ether was placed in a three-necked flask (1 g.-mol. of Si_2OCl_4 being dissolved in approx. 1 l. of ether), fitted with a stirrer, a spiral double-surface condenser, and tap-funnel. The Grignard solution was filtered through glass-wool into the tap-funnel to remove excess of magnesium, and then run slowly into the well-stirred solution of the halide. Precipitation of magnesium chlorobromide began at once. When the addition was complete, the solution was refluxed for 3–6 hours to ensure completion of the reaction. The reaction mixture was allowed to cool, and the chlorobromide filtered off rapidly through a large Büchner funnel. The residue on the filter was well washed with anhydrous ether. Removal of the ether was carried out by distillation, and the residue was then fractionated. Arrangements were made, by means of drying tubes containing silica gel, to exclude moisture from the reaction vessel, distillation columns, and other apparatus in which the halides were handled. All apparatus was thoroughly dried before use.

Monoethylpentachlorodisiloxane.—116 G. (0.875 g.-mol.) of ethylmagnesium bromide were treated with 200 g. (0.7 g.-mol.) of Si_2OCl_4 . The products after separation were fractionated several times under reduced pressure, a 13" column packed with Fenske spirals being used. 47 G. (0.17 g.-mol.) of pure monoethylpentachlorodisiloxane were obtained (b. p. 60.0–61.5°/17 mm., 163–164°/757 mm.); yields, crude 40%, pure 24% (Found: Cl, 63.6; Si, 19.9; C, 8.9; H, 1.9. $\text{Si}_2\text{OCl}_4\text{Et}$ requires Cl, 63.7; Si, 20.1; C, 8.7; H, 1.8%).

Diethyltetrachlorodisiloxane.—333 G. (2.5 g.-mols.) of ethylmagnesium bromide were treated with 285 g. (1 g.-mol.) of Si_2OCl_4 . 236 G. (87%) of crude product were obtained, from which 75 g. (0.28 g.-mol., 28%) of pure diethyltetrachlorodisiloxane were collected (b. p. 72.5°/12 mm., 186–187°/757 mm.) by fractionation under reduced pressure through a modified Widmer column, packed with Monel-metal gauze spirals and utilising a partial condensation vapour take-off head (Found: Cl, 52.3; Si, 20.6; C, 17.9; H, 3.7. $\text{Si}_2\text{OCl}_4\text{Et}_2$ requires Cl, 52.1; Si, 20.6; C, 17.7; H, 3.7%).

Triethyltrichlorodisiloxane.—498 G. (3.75 g.-mols.) of ethylmagnesium bromide were caused to react with 285 g. (1 g.-mol.) of Si_2OCl_4 . 231 G. (85%) of crude product were obtained, from which, by repeated fractionation under reduced pressure by means of the column described in the previous preparation, it was possible to isolate 78 g. (0.295 g.-mol., 29.5%) of pure triethyltrichlorodisiloxane (b. p. 72.5–73.5°/7 mm., 202–203°/757 mm.) (Found: Cl, 40.0; Si, 21.5; C, 26.8; H, 5.7. $\text{Si}_2\text{OCl}_4\text{Et}_3$ requires Cl, 40.0; Si, 21.1; C, 27.1; H, 5.7%).

Tetraethyldichlorodisiloxane.—An attempt to prepare the pentaethylmonochloro-compound by

reaction of 1 g.-mol. of Si_2OCl_4 with 5 g.-mols. of ethylmagnesium bromide led to the isolation of *tetraethyldichlorodisiloxane*. When 6.25 g.-mols. of the Grignard reagent were used, difficulty was experienced in separating the product owing to the bulk of the magnesium chlorobromide, and this bulk of inert product probably accounts for the reaction ceasing at the tetra-substituted stage. 19.4 G. (78%) of crude tetraethyl compound were obtained, which after repeated fractionation gave 29 g. (0.11 g.-mol., 11%) of pure product (b. p. $96-98^\circ/13$ mm., $215-216^\circ/757$ mm.) (Found: Cl, 27.4; Si, 20.9; C, 36.9; H, 7.4. $\text{Si}_2\text{OCl}_2\text{Et}_4$ requires Cl, 27.4; Si, 21.6; C, 37.0; H, 7.8%). 12 G. of a fraction consisting mainly of pentaethyl compound were obtained.

Pentaethylmonochlorodisiloxane.—The preparation of this compound was carried out in two stages. The triethyl compound was first prepared as described above, the crude material being isolated and analysed for replaceable chlorine. An amount of ethylmagnesium bromide (366 g., 2.75 g.-mols.) was prepared sufficient to reduce the content of the replaceable chlorine in 293 g. of triethyl compound to that corresponding to $\text{Si}_2\text{OClEt}_3$, together with the usual 25% excess of Grignard reagent over the halide. Reaction was slower than when the unsubstituted chloride was used and it was necessary to reflux the mixture overnight. 237 G. of crude material were obtained, from which it was possible after repeated fractionations under reduced pressure to obtain 34 g. (0.135 g.-mol., 12.5%) of pure *pentaethyl* compound (b. p. $86-88^\circ/1$ mm., $226-227^\circ/757$ mm.) (Found: Cl, 13.9; C, 48.1; H, 10.5. $\text{Si}_2\text{OClEt}_3$ requires Cl, 14.0; C, 47.5; H, 10.0%).

Dimethyltetrachlorodisiloxane.—17 G. (0.1 g.-mol.) of methylmagnesium iodide and 179 g. (2.4 g.-mols.) of methylmagnesium chloride, prepared according to Schmalfuss (*J. pr. Chem.*, 1924, 108, 88), were treated with 285 g. (1 g.-mol.) of Si_2OCl_4 . Reaction proceeded vigorously and the vessel had to be cooled during the early stages of the preparation. 203 G. of crude material were obtained. By using a 28" column filled with Monel-metal gauze spirals and fitted with a heater jacket and utilising a total condensation partial take-off head, 137 g. (0.56 g.-mol., 56%) of pure *dimethyltetrachlorodisiloxane* were obtained (b. p. $67-69^\circ/57$ mm., $143-144^\circ/757$ mm.) (Found: Cl, 57.5; Si, 23.2; C, 10.2; H, 2.5. $\text{Si}_2\text{OCl}_4\text{Me}_2$ required Cl, 58.1; Si, 23.1; C, 9.9; H, 2.5%). The pure material was colourless but became pink in contact with air.

Diphenyltetrachlorodisiloxane.—520 G. (2.85 g.-mols.) of phenylmagnesium bromide reacted with 285 g. (1 g.-mol.) of Si_2OCl_4 . The crude product was separated from the small quantity of diphenyl obtained by fractionation through a 9' Fenske column, fitted with a heater jacket and utilising a total condensation partial take-off head. Further fractionation using the 28" Monel-gauze spiral column used in the previous preparation led to the isolation of 64 g. (0.175 g.-mol., 17.5%) of pure compound (b. p. $114-116^\circ/<1$ mm., $319-320^\circ/757$ mm.) (Found: Cl, 38.6; Si, 15.1; C, 39.2; H, 2.6. $\text{Si}_2\text{OCl}_4\text{Ph}_2$ requires Cl, 38.5; Si, 15.2; C, 39.2; H, 2.7%). The pure material was colourless but on storage became pale yellow.

Pentaethyldisiloxanol.—3 G. of pentaethylchlorodisiloxane were dissolved in 15 ml. of ether and a solution containing 2 g. of sodium hydrogen carbonate dissolved in 10 ml. of water added. A steady evolution of carbon dioxide occurred for 2 hours. The solution was refluxed for a further 3 hours until the evolution ceased. The solution was extracted with portions of ether, the resulting ethereal solution was separated and dried (CaCl_2) overnight. The ether was removed by distillation, and the product distilled under reduced pressure. 2.5 G. (100%) of the *siloxanol* were obtained (b. p. $96-98^\circ/<1$ mm.) [Found: C, 51.4; H, 11.1; *M* (Rast), 215. $\text{Si}_2\text{OEt}_4\text{OH}$ requires C, 51.3; H, 11.1% *M*, 232].

Photochemical Chlorination of Diethyltetrachlorodisiloxane.—Dry chlorine was passed into 32.2 g. of the disiloxane contained in a quartz test-tube irradiated by U.V. light from a mercury-vapour lamp. After 66 hours the increase in weight was 40.5 g. [Calc. for formation of $\text{Si}_2\text{OCl}_4(\text{C}_2\text{Cl}_5)_2$: 40.8 g.]. The bulk of the *bispentachloroethyltetrachlorodisiloxane* distilled within the range $178-183^\circ/<1$ mm. and consisted of a colourless viscous liquid with a faint smell [Found: Cl, 81.1; *M* (Rast), ~650. $\text{C}_4\text{OCl}_4\text{Si}_2$ requires Cl, 80.6%; *M*, 617].

317. Alkyl, Aryl, and Alkoxy-derivatives of Silicon Tetrachloride and Silicochloroform.

By H. J. EMELÉUS and S. R. ROBINSON.

The compounds *ethyldichlorosilane*, *diethylchlorosilane*, *phenyldichlorosilane*, *diphenylchlorosilane*, *benzyldichlorosilane*, and *dibenzylchlorosilane* have been prepared from silicochloroform by the Grignard reaction. A new method for the preparation of alkyl-alkoxysilanes by the reaction between sodium alkoxide and an alkyl silicon chloride is reported. *Diethyldimethoxysilane* is described. Other known compounds of this type were prepared by the same method and characterised.

THE alkyl, aryl, and alkoxy-derivatives of silicochloroform and silicon tetrachloride are of importance because on hydrolysis they give materials which are known to form resins when heated. The preparation of these resin intermediates from silicochloroform is in fact a useful alternative to their preparation by hydrolysis of the corresponding derivatives of silicon tetrachloride. The only reference in the literature to compounds of the type SiRHX_3 , where X

is a halogen atom, is in work by Rochow (*J. Amer. Chem. Soc.*, 1945, **67**, 963), who states that if the reaction between methyl chloride and copper-silicon is conducted under conditions such that some pyrolysis of the free hydrocarbon radicals occurs, halogenated products of the type SiRHX_2 appear in the product. Products in which the chlorine of silicochloroform is completely substituted are, however, known. For example, trimethoxysilane has been prepared from silicochloroform and methyl alcohol (Helfferich and Hausen, *Ber.*, 1924, **57**, 795). The corresponding trialkyl compounds have been obtained by the action of zinc alkyls on ethyl orthosilicate (Ladenburg, *Annalen*, 1872, **164**, 301; Pape, *Ber.*, 1881, **14**, 1873), and triphenylsilane has been prepared by various methods (Kipping and Murray, *J.*, 1929, 360; Reynolds, Bigelow, and Kraus, *J. Amer. Chem. Soc.*, 1929, **51**, 3067; Kraus and Eatough, *ibid.*, 1933, **55**, 5008). The preparations now described are of *ethyl*-, *phenyl*-, and *benzyl-dichlorosilane*, and *di-ethyl*-, *-phenyl*-, and *-benzyl-chlorosilane*, all of which were obtained by using the Grignard reaction. The alkyl-alkoxy-compounds described are related to the derivatives of silicochloroform by the fact that the alkyl (or aryl) groups are in both cases the only ones resistant to hydrolysis.

EXPERIMENTAL.

Silicochloroform was prepared by passing hydrogen chloride over powdered silicon at 380° (Booth and Stillwell, *J. Amer. Chem. Soc.*, 1934, **56**, 1529). The product was fractionated through a 16-inch Fenske column, the fraction of b. p. 31–34° being used in the following preparations.

Ethyl-dichlorosilane.—1.25 G.-mol. of ethylmagnesium bromide in 500 ml. of ether were added slowly to an ice-cooled, mechanically stirred solution of 135.5 g. of silicochloroform in 100 ml. of ether. The reaction mixture was heated under reflux for 4 hours, filtered, and the ethereal solution fractionated through a 16-inch Fenske column fitted with a reflux head, using a reflux ratio of 5 : 1. After removal of the ether, the following four fractions were obtained: (a) b. p. < 74° (8 g.), (b) b. p. 74.5–75.5° (39 g.), (c) b. p. 75.6–95° (6 g.), (d) b. p. 95–98° (5.5 g.). Analysis of fraction (b) gave: Si, 21.6; Cl, 54.7; C, 19.0; H, 4.7. ($\text{C}_2\text{H}_5\text{Cl}_2\text{Si}$ requires Si, 21.7; Cl, 54.9; C, 18.6; H, 4.7%). A determination of the molecular weight by the Dumas method gave 134.1 (Calc.: 129.1). The vapour-pressure curve of this compound between –17° and 70° was measured by means of an isoteniscope. The vapour-pressure data are represented by the equation $\log p = 7.6271 - 1648.2/T$; the b. p. was 74.2°, and Trouton's constant 20.4. Fraction (d) was shown by chlorine analysis to be a mixture of the mono- and the di-ethyl compound.

The silicochloroform derivatives described below were prepared by the same method, a suitable proportion of the appropriate Grignard reagent being used. In each case a series of fractions was obtained, one of which preponderated and corresponded to the desired product.

Diethylchlorosilane.—A fraction of b. p. 97–105° was refractionated through a Fenske column and gave this compound, b. p. 99–100°. The yield of purified product was 19% (Found: Si, 22.9; Cl, 28.9; C, 39.1; H, 9.1; *M*, by Dumas method, 126.8, 128.1. SiEt_2ClH requires Si, 22.9; Cl, 28.9; C, 39.15; H, 9.0%; *M*, 122.7). The equation to the vapour pressure curve for the range 0–94° was $\log p = 7.4195 - 1689.5/T$. The b. p. and Trouton's constant were 99.2° and 19.5, respectively.

Methyldichlorosilane.—The Grignard compound used was methylmagnesium chloride in *n*-butyl ether (Schmalfuss, *J. pr. Chem.*, 1924, **108**, 88). A fraction of b. p. 40.7° was obtained which proved to be the desired compound (Found: Si, 22.9; Cl, 61.9; C, 10.0; H, 4.6. SiMeCl_2H requires Si, 24.4; Cl, 61.7; C, 10.4; H, 3.5%). In this preparation three fractions were collected between 33° and 40.5°, and there was difficulty in obtaining a complete separation.

Phenyldichlorosilane.—A fraction of b. p. 118–119°/25 mm. was twice refractionated and gave a fraction, b. p. 65.0–65.3°/10 mm., of *phenyldichlorosilane* (Found: Cl, 40.2; C, 40.8; H, 3.5. SiPhCl_2H requires Cl, 40.0; C, 40.7; H, 3.4%).

Diphenylchlorosilane.—A fraction of b. p. 147–170°/10 mm. was refractionated and gave a fraction, b. p. 140–145°/7 mm., of the *chlorosilane* (Found: Si, 12.4; Cl, 16.3; C, 66.3; H, 5.3. SiPh_2ClH requires Si, 12.8; Cl, 16.2; C, 66.0; H, 5.1%).

Benzyl-dichlorosilane had b. p. 48°/2 mm. (Found: Si, 14.6; Cl, 37.0; C, 45.8; H, 4.2. $\text{Si}(\text{CH}_2\text{Ph})\text{Cl}_2\text{H}$ requires Si, 14.7; Cl, 37.0; C, 46.1; H, 4.2%), and *di-benzylchlorosilane* b. p. 146–148°/ca. 1 mm. (Found: Si, 11.5; Cl, 14.6; C, 67.5; H, 6.2; $\text{Si}(\text{CH}_2\text{Ph})_2\text{ClH}$ required Si, 11.4; Cl, 14.4; C, 68.1; H, 6.1%).

Alkylalkoxysilanes.—The four compounds of this type prepared were ethyltriethoxy-, diethyldiethoxy-, ethyltrimethoxy-, and diethyldimethoxy-silane. Ladenburg's method of preparation (*Annalen*, 1874, **173**, 143) using the reaction between diethyl zinc and the appropriate silicon ester is not convenient. Reaction between Grignard compounds and esters of orthosilicic acid has been used by Post and Hofrichter (*J. Org. Chem.*, 1939, **4**, 363), and Adrianov (*J. Gen. Chem. U.S.S.R.*, 1938, **8**, 558, 1255; 1939, **9**, 203) has prepared monosubstituted derivatives of the type $\text{SiR}(\text{OEt})_3$ by forming the Grignard compound *in situ* from the alkyl halide and magnesium in presence of ethyl orthosilicate, with which reaction then occurs. It is not possible by means of the ordinary Grignard reaction to substitute more than one of the alkoxy-groups of an orthosilicic ester.

The direct method of preparing compounds of this type is by reaction of the alkylsilicon chloride with an alcohol. The alcohol must be completely dry or much material of high molecular weight is obtained; e.g., Friedel and Crafts (*Annalen*, 1865, **136**, 203) found that in the reaction between silicon tetrachloride and methanol, two compounds, $\text{Si}(\text{OMe})_4$ and $\text{Si}(\text{MeO})_3\cdot\text{O}\cdot\text{Si}(\text{OMe})_3$, were obtained. Our preliminary experiments showed that on refluxing diethylsilicon dichloride and ethyl alcohol together, a considerable quantity of ethyl chloride was formed. This was isolated and characterised by its vapour-pressure curve; it is presumably formed in the secondary reaction between the alcohol and hydrogen chloride,

which yields the alkyl halide and water. Thus, even if the alcohol is initially dry, this water will inevitably lead to the production of more complex products. This difficulty has been overcome by using the sodium derivative of the alcohol in place of the alcohol itself.

The ethylsilicon halides required as intermediates were prepared by means of the Grignard reaction (Kipping, *J.*, 1907, **91**, 209). The sodium alkoxide was prepared by adding sodium in small pieces to an excess of the pure alcohol in a flask fitted with a reflux condenser, boiling off the excess of alcohol at the completion of the reaction, and removing the residual alcohol in an oil-pump vacuum. The product was a fine white powder.

The theoretical quantity of sodium ethoxide covered with ether was placed in a three-necked flask fitted with a mechanical stirrer, reflux condenser, and tap-funnel. The suspension was well stirred, and a solution of the theoretical quantity of ethylsilicon trichloride in an equal volume of ether was added slowly. The product was refluxed for an hour, transferred to a Kon flask and distilled. Ethyltriethoxysilane was collected at 155–160° and redistilled; b. p. 158–160°, yield 40% (Found : Si, 14.73, 14.65. Calc. for $C_6H_{18}O_3Si$: Si, 14.60%).

Similar preparations were carried out for diethyldiethoxysilane (b. p. 156–157°, yield, 40%), ethyltrimethoxysilane (b. p. 123°, yield 58%), and *diethyldimethoxysilane* (b. p. 130°, yield 70%) (Found : Si, 18.75, 18.96, 18.78; *M*, by Dumas method, 151.0, 153.3, 152.5. $C_6H_{16}O_2Si$ requires Si, 18.92%; *M*, 148.3).

The vapour-pressure curves of these compounds were studied by means of an isoteniscope technique, the results being tabulated below.

Compound.	Vapour-pressure relationship.	B. p.	Latent heat, cal./g.-mol.	Trouton's constant.
$SiEt(OEt)_3$	$\log p = 7.4759 - 1980.5/T$	158.9°	9085	21.03
$SiEt_2(OEt)_2$	$\log p = 7.3896 - 1940.5/T$	157.3	8883	20.64
$SiEt(OEt)_2$	$\log p = 7.8760 - 1968.1/T$	120.9	9007	22.86
$SiEt_2(OMe)_2$	$\log p = 7.912 - 2018.5/T$	128.1	9240	23.03

318. Studies in the Azole Series. Part I. A Novel Route to 5-Aminothiazoles.

By A. H. COOK, SIR IAN HEILBRON, and A. L. LEVY.

Dithiophenylacetic acid reacts with aminoacetonitrile or ethyl aminocynoacetate to give 5-amino- and 5-amino-4-carbethoxy-2-benzylthiazole, (III) and (II; R = Et), respectively. The behaviour of these bases towards acylating agents, nitrous acid, and in the case of the first-mentioned towards diazonium salts, nitrating agents, etc., is described. This seems a general synthesis of the hitherto almost unknown class of 5-aminothiazoles, 5-amino-4-phenyl- and 5-amino-4-carbethoxy-thiazole being obtained analogously.

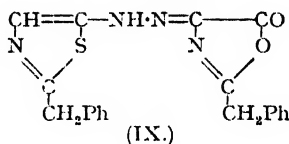

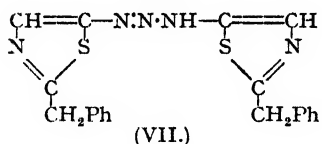

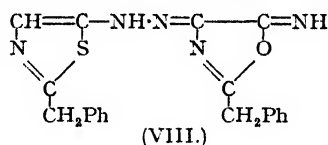

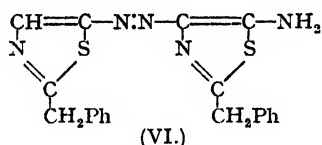

In connection with the study of penicillin (unpublished work) the reaction between sodium or methyl dithiophenylacetate and ethyl aminocynoacetate was examined. The product was at first thought to be ethyl phenylthionacetamidocynoacetate (I) but subsequent investigation showed that it was a base which could be better formulated as 5-amino-4-carbethoxy-2-benzylthiazole (II; R = Et). It formed a stable hydrochloride and on hydrolysis gave the corresponding acid (II; R = H). Hexoylation yielded 5-hexoamido-4-carbethoxy-2-benzylthiazole which still exhibited basic properties. Similarly, aminoacetonitrile and sodium dithiophenylacetate afforded an excellent yield of a base which by analogy is formulated as 5-amino-2-benzylthiazole (III). Its light absorption is compatible with this formulation and is

very similar to that of the corresponding 4-carbethoxy-compound above. It seems that phenylthionacetamidocetonitrile (IV) occurs as an intermediate and cyclises on warming, for a small amount of an alkali-soluble isomeride was isolated from the crude aminothiazole. The isomeride passed into the aminothiazole on being kept with hydrogen chloride in organic solvents and appears therefore to be the acyclic thioamide. This facile formation of 5-aminothiazoles is

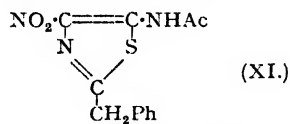

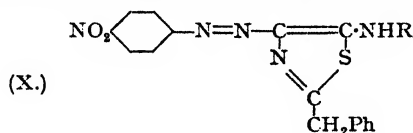

of interest as they have been so far almost unknown in the literature. Weidel and Niemilowicz (*Monatsh.*, 1895, 16, 721) described some degradation products of uric acid which are possibly derivatives of 5-aminothiazole. The only other noteworthy reference is to a series of derivatives of 5-amino-2-thiocarboxyamidothiazole ("chrysean") originating in the interaction of hydrocyanic acid and hydrogen sulphide (see Beilstein's "Handbuch", Vol. 27, 334; Arnold and Scaife, *J.*, 1944, 103). Jensen and Hansen (*Dansk Tids. Farm.*, 1943, 17, 189) and Ganapathi and Venkataraman (*Proc. Indian Acad. Sci.*, 1945, 22A, 343) have recently prepared some 5-aminothiazoles by orthodox reactions but the methods are not entirely satisfactory in scope and yield.

5-Amino-2-benzylthiazole formed a *hydrochloride* and on acetylation gave 5-acetamido-2-benzylthiazole (V) which had marked basic properties, and formed a *hydrochloride* and a *methiodide*; the latter clearly contained a "reactive" methylene group (in the adjacent benzyl substituent) and developed an intense cyanine-like colour on being heated with ethyl orthoformate under appropriate conditions. The 5-acetylsulphanilamido- and 5-sulphanilamido-compounds were also prepared. The sulphanilamide inhibited the growth of *Staph. aureus* at a limiting dilution of 1 : 50,000, but the inhibition was not complete, and even at 1 : 5000 abnormal agglutinated clumps of bacterial growth were observed. When (III) was treated with 1 mol. of nitrous acid there was some evolution of hydrogen sulphide and rapid appearance of a deep red-brown precipitate from which two products were isolated, $C_{20}H_{17}N_5S_2$ (A) and $C_{20}H_{17}ON_5S$ (B). The former formed brilliant crystals with a copper-like lustre and gave deep red solutions. The fact that (II) failed to behave similarly with nitrous acid supports structure (VI) rather than (VII) (cf. formation of aminoazobenzene). Formulation (VI), representing a diazonium salt coupling with a second molecule of amine in the 4-position, is perhaps novel to thiazole chemistry but strictly comparable with *ortho*-coupling of aromatic amines; it is supported by the fact that (V) couples with diazonium salts whereas (II) does not share this ability.

Product (B) formally contained a sulphur atom of (A) replaced by oxygen, but in view of its paler colour and altered light absorption it is tentatively formulated as the imino-compound (VIII). This formulation is in keeping with its behaviour on hydrolysis with cold dilute hydrochloric acid, which gave a compound $C_{20}H_{16}O_2N_5S$, obviously the oxazolone (IX).

It was mentioned above that (III) coupled with diazonium salts, and in illustration the orange-scarlet *azo*-compound (X; R = H) was prepared. The acetamido-compound (V) likewise coupled to give (X; R = Ac). Both *azo*-compounds were remarkable in giving intense violet colorations with caustic alkalis. When (V) was treated with nitrosyl chloride in acetic acid in an attempt to obtain the *N*-nitroso-derivative ("diazonium acetate") the sole product isolated was a nitro-compound which, in view of the ready reactivity of the 4-position, is obviously 4-nitro-5-acetamido-2-benzylthiazole (XI). In this connection it may be noted that nitrous acid not infrequently acts as a nitrating agent (*e.g.*, Hodgson, *J.*, 1932, 1812). Compound (XI) was also produced by direct nitration of (IV) with a nitric-sulphuric acid mixture, and by treatment of its *nitrate* with sulphuric acid in acetic acid solution.

Similar syntheses have been carried out by employing sodium dithioformate in place of dithiophenylacetate. As the reaction with aminoacetonitrile is complex, and in view of its special interest, it will form the subject of a separate communication. With ethyl aminocyno-

acetate reaction was facile, giving *5-amino-4-carbethoxythiazole* identical with the product obtained by heating the analogous 2-mercaptothiazole (see following paper) with Raney nickel. In the same way α -aminobenzyl cyanide and sodium dithioformate afforded *5-amino-4-phenylthiazole*, characterised as its *hydrochloride* and *acetyl* derivative, and likewise identified with the base obtained by desulphurising the analogous 2-mercaptothiazole.

It is noteworthy that all the ring-syntheses described here take place at room temperature, several of them in aqueous neutral solution.

Light-absorption data on the aminothiazole derivatives are recorded on p. 1598 in tabular form (cf. table in Part II).

Methyl ethylxanthate failed to exhibit the reactivity of the above dithio-acid derivatives towards α -amino-nitriles. On the other hand, it behaved as a "thioacylating" agent towards strong bases; e.g., it gives with morpholine *N-monothiocarboethoxymorpholine*.

EXPERIMENTAL.

(a) Crude ethyl aminocynoacetate (3 g.), prepared by reducing ethyl nitrosocynoacetate with amalgamated aluminium, was allowed to stand with methyl dithiophenylacetate (4 g.). Heat and thiol were evolved spontaneously and after a few minutes the mixture set to a mass of yellow needles. Treatment with a small quantity of ether gave almost pure *5-amino-4-carbethoxy-2-benzylthiazole* (II; R = Et) (3.6 g., a further 0.8 g. being recovered from the ethereal residues). It separated from ethanol in long colourless needles, m. p. 157° (Found: C, 59.8; H, 5.6; N, 10.9. $C_{13}H_{14}O_2N_2S$ requires C, 59.5; H, 5.4; N, 10.7%).

(b) Ethyl aminocynoacetate (5 g.) was shaken overnight in ether (50 c.c.) with sodium dithiophenylacetate (1 equiv.) in water (20 c.c.). Evaporation of the dried ethereal solution gave the free base, *5-amino-4-carbethoxy-2-benzylthiazole*, in poor yield, m. p. 156°. The thiazole (780 mg.) in dioxan (3 c.c.) and water (7 c.c.) was kept with 0.51N-sodium hydroxide (6 c.c.) overnight and then heated on the steam-bath for two hours. The filtrate was acidified with dilute hydrochloric acid, and the acid recrystallised from ethanol. *5-Amino-4-carboxy-2-benzylthiazole* separated in irregular prisms, m. p. 169° with violent evolution of gas (on slow heating) (Found: C, 56.5; H, 4.6; N, 12.0. $C_{11}H_{10}O_3N_2S$ requires C, 56.4; H, 4.3; N, 12.0%). Small quantities of this acid were obtained as a by-product during the preparation of the ester *via* sodium dithiophenylacetate.

The ester-thiazole (II) (0.52 g.) suspended in ethanol (5 c.c.) was treated with hydrogen chloride at -10° . After 12 hours at 20° the solution was evaporated in a vacuum, and the solid, m. p. 180°, washed with ether and crystallised from ethanol-ether. *5-Amino-4-carbethoxy-2-benzylthiazole hydrochloride* separated in rectangular plates, m. p. 180° (Found: C, 52.3; H, 5.5, 5.2; N, 9.7. $C_{13}H_{14}O_2N_2S \cdot ClH$ requires C, 52.5; H, 5.1; N, 9.4%). The ester-thiazole (II) (1 g.), *n*-hexoyl chloride (0.7 g.), and pyridine (20 c.c.) were heated together at $80-90^\circ$ for 2 hours, and the mixture evaporated in a vacuum. The residue was extracted with ether but the base remained oily on evaporation of solvent. Addition of ethereal hydrogen chloride gave a solid. *5-n-Hexamido-4-carbethoxy-2-benzylthiazole hydrochloride* crystallised from chloroform-light petroleum in clumps of feathery needles, m. p. 110°, which lost hydrogen chloride on heating to 56° in a vacuum and were dried at room temperature over phosphoric oxide (Found: C, 57.5; H, 6.7. $C_{16}H_{20}O_2N_2S \cdot ClH$ requires C, 57.5; H, 6.3%).

Aminoacetone nitrile sulphate (135 g.) in water (200 c.c.) was neutralised (brilliant-yellow) with potassium hydroxide (98 g.) in water (230 c.c.) in the cold. A neutral solution of potassium dithiophenylacetate (1 equiv.) in water (510 c.c.) was added with ether (1500 c.c.), the solution again brought to neutrality, and the whole shaken overnight. On separation of the ethereal layer and removal of solvent, the residual oil solidified (yield, 165 g., 98%). Crude *5-amino-2-benzylthiazole* (III) crystallised from ether-light petroleum or chloroform-light petroleum to form colourless needles, m. p. 87° (130 g.), which darkened on exposure to light (Found: C, 63.5; H, 5.5; N, 14.5. $C_{10}H_{10}N_2S$ requires C, 63.2; H, 5.3; N, 14.7%). The crude product, m. p. 83° (1.0 g.), was stood for 3 days in a mixture of dioxan (5.0 c.c.) and water (8.0 c.c.), and the product (0.2 g.) which separated recrystallised from ethanol to give colourless needles, m. p. 161° (decomp.), of *phenylthionacetamidoacetone nitrile* (IV) (Found: C, 63.0; H, 5.2; N, 14.8. $C_{10}H_{10}N_4S$ requires C, 63.2; H, 5.3; N, 14.7%). The compound was soluble in aqueous-alcoholic potash and was transformed by ethanolic hydrogen chloride into *5-amino-2-benzylthiazole hydrochloride*, m. p. and mixed m. p. 195° (decomp.).

The base could be conveniently converted into its hydrochloride by several methods; e.g., the base was covered with 3 vols. of warm ethanol and a little water and treated with a little ethanolic hydrogen chloride. This technique was only necessary when starting with the hydrochloride, which was insoluble in dry ethanol, but soluble in the wet solvent. The *hydrochloride* separated and could be recrystallised in the same manner, forming rectangular tablets, m. p. 194° (decomp.) (Found: C, 53.0; H, 4.9; N, 12.4. $C_{10}H_{11}N_2S \cdot ClH$ requires C, 53.0; H, 4.9; N, 12.4%).

5-Amino-2-benzylthiazole (1 g.) was treated with acetic anhydride (1 c.c.). The mixture became very hot, and on being rubbed with light petroleum set to a mass of yellowish crystals (yield, 1.2 g.). *5-Acetamido-2-benzylthiazole* (V) crystallised excellently from benzene, or a mixture of ethyl acetate, ethanol, or acetone with light petroleum, in square plates, m. p. 121° (Found: C, 61.8; H, 5.3; N, 11.7. $C_{12}H_{13}ON_2S$ requires C, 62.1; H, 5.2; N, 12.1%). It crystallised from water or aqueous solvents as a hydrate, m. p. $74-75^\circ$, in long hair-like needles.

The compound was set aside with cold ethanolic hydrogen chloride for 2 days. It passed into solution (4 hours) and *5-amino-2-benzylthiazole hydrochloride*, m. p. 194° (decomp.), crystallised cleanly from the colourless solution in good yield. The acetyl compound (0.95 g.) in concentrated hydrochloric acid (5 c.c.) was cooled to -10° and a little water added. The well-formed crystals were filtered off and

washed with a little acetone. 5-Acetamido-2-benzylthiazole hydrochloride separated from ethanol-acetone in laths, m. p. 204–206°, which were very stable and did not discolour at 250° (Found : C, 53.7; H, 5.0; N, 10.5. $C_{11}H_{13}ON_2S$ requires C, 53.6; H, 4.9; N, 10.4%). The same compound was obtained by adding ethereal hydrogen chloride to a solution of the base in acetone. The acetyl compound (1 g.) was refluxed with methyl iodide (2 c.c.) in acetone (10 c.c.) for 30 minutes, and the quaternary salt filtered off. It was insoluble in hot acetone and sparingly soluble in cold water, but crystallised from acetic acid (needles), water (rectangular tablets), or spirit (laths); 5-acetamido-2-benzylthiazole methiodide had m. p. 265° (Found : C, 41.9; H, 4.1; N, 7.4. $C_{11}H_{13}ON_2SI$ requires C, 41.7; H, 4.0; N, 7.5%). It gave intense blood-red colours with 1 : 3 : 3-trimethyl-2-methyleneindoline- ω -aldehyde or ethyl orthoformate in hot acetic anhydride-pyridine.

5-Amino-2-benzylthiazole (9.5 g.) in ice-cold ethanol (280 c.c.) was treated during 15 minutes with stirring with ice-cold *N*-sodium nitrite (50 c.c.) to which had been added 0.474*N*-hydrochloric acid (105 c.c., 1 equiv.). The solution became orange and deposited red-brown crystals; these increased as the solution was allowed to assume room temperature and were filtered off (yield, 11 g.) after 40 minutes; some evolution of hydrogen sulphide was noticed. The solid was extracted with boiling benzene (100 c.c.); the residue (3.5 g.) of bright orange-red powder (A) could be supplemented by a small quantity obtained from the alcoholic mother-liquor above. (A) was insoluble in water, ether, and light petroleum, slightly soluble in hot ethanol, acetone, chloroform, or ethyl acetate, readily soluble in hot acetic acid. It crystallised from acetic acid, nitrobenzene or much toluene in coppery, rectangular tablets or needles, m. p. 213° (Found : C, 61.2; H, 4.2; N, 17.4. $C_{20}H_{17}N_3S_2$ requires C, 61.4; H, 4.4; N, 17.9%), formulated as the *azo*-compound (VI). Light absorption (chloroform) : λ max. = 281, 291, 308 $m\mu$, $E_{1\%}^{1cm}$ = 230; 453 $m\mu$, $E_{1\%}^{1cm}$ = 660. It was insoluble in sodium hydrogen carbonate solution, apparently slowly changed by hot aqueous sodium hydroxide, gave a brown hydrochloride when its chloroform solution was treated with ethanolic hydrogen chloride, and gave a deep red solution in concentrated sulphuric acid. The benzene mother-liquors (above) were chromatographed on alumina; material (B), obtained from a sharp brown band on developing with benzene-ethanol (1 : 1), recrystallised from chloroform-light petroleum in pale yellow rectangular plates, m. p. 139° (Found : C, 64.2; H, 4.7; N, 18.4. $C_{20}H_{17}ON_2S$ requires C, 64.0; H, 4.6; N, 18.6%); in a later preparation the chromatography could be omitted. (B) is perhaps best formulated as the *imino*-derivative (VIII); it was insoluble in cold water, aqueous sodium hydrogen carbonate, and sodium hydroxide, but was changed by warm dilute mineral acid. Light absorption (ethanol) : λ max. = 265, 322 $m\mu$, $E_{1\%}^{1cm}$ = 200, 250. The imino-derivative was dissolved in warm methanol and diluted with warm 2*N*-hydrochloric acid. On cooling, the *oxazolone* derivative (IX) separated, filling the tube with crystals, m. p. 116°, which recrystallised from methanol in platelets, m. p. 114–116° (Found : C, 62.4; H, 4.6; N, 13.9. $C_{20}H_{15}O_2N_2S$, MeOH requires C, 61.8; H, 4.9; N, 13.7%). Heating at 100° in a vacuum raises the m. p. to 202–205°. Light absorption (ethanol) : λ max. = 301 $m\mu$, $E_{1\%}^{1cm}$ = 290.

5-Amino-2-benzylthiazole (1 g.) in ethanol (30 c.c.) containing potassium acetate was treated with a diazonium salt solution prepared with *p*-nitroaniline (0.7 g.) in excess of 8% hydrochloric acid. The vessel was immediately filled with a highly crystalline scarlet precipitate of the *azo*-dye (2.3 g., m. p. 140°). It crystallised fairly well from ethanol, isopropanol, *tert*-butanol, or chloroform-ether; it also crystallised from acetic acid but was partly transformed into green crystals, though the nature of this change is obscure. 5-Amino-4-*p*-nitrobenzenazo-2-benzylthiazole (X; R = H) crystallised best from toluene containing a little nitrobenzene and then formed rust-brown needles, m. p. 158° on rather rapid heating (Found : C, 56.8; H, 3.6; N, 20.3. $C_{16}H_{13}O_2N_3S$ requires C, 56.6; H, 3.9; N, 20.6%); it gave an intense purple solution with alkali.

Diazotised *p*-nitroaniline was coupled similarly with 5-acetamido-2-benzylthiazole. Coupling was slower and the colour (orange) less intense than with the aminothiazole. The dye was moderately soluble in ether or ethanol, easily soluble in the cold in chloroform, ethyl acetate or acetone. 5-Acetamido-4-*p*-nitrobenzenazo-2-benzylthiazole (X; R = Ac) crystallised from aqueous acetone or benzene in laths, m. p. 175–176° (Found : C, 57.2; H, 4.1; N, 18.0. $C_{18}H_{15}O_2N_3S$ requires C, 56.7; H, 4.0; N, 18.4%); it also gave a magnificent purple colour with sodium hydroxide.

5-Amino-2-benzylthiazole (1.9 g.) and acetylsulphanilyl chloride (2 g.) were kept together in pyridine (5 c.c.) overnight, and the solution poured into water. The oil soon crystallised (yield, 3.2 g.); 5-acetylsulphanilamido-2-benzylthiazole crystallised from ethyl acetate containing a little ethanol, or from aqueous acetone, in needles, m. p. 189° (Found : C, 55.7; H, 4.4. $C_{18}H_{17}O_2N_3S_2$ requires C, 55.8; H, 4.4%). The acetylsulphanilamide (1.5 g.) was refluxed with 2*N*-hydrochloric acid (20 c.c.) for 0.5 hour. Filtration from a little gum and addition of concentrated aqueous sodium acetate gave 5-sulphanilamido-2-benzylthiazole (1 g.), which crystallised from dilute ethanol in prismatic needles, m. p. 182° (Found : C, 55.4; H, 4.4; N, 11.8. $C_{10}H_{15}O_2N_3S_2$ requires C, 55.6; H, 4.3; N, 12.2%).

5-Acetamido-2-benzylthiazole (1.25 g.) in 0.5*N*-hydrochloric acid (10 c.c.) and dioxan to give a permanent solution was treated with *N*-sodium nitrite (10 c.c.) at 0°. After standing for one week the brownish needles were collected and recrystallised from aqueous methanol. This compound was 5-acetamido-2-benzylthiazole nitrate and was obtained from the base and nitric acid in alcohol; it separated in colourless needles, m. p. 111° (decomp.) (Found : C, 48.9; H, 4.3; N, 14.2. $C_{12}H_{13}O_4N_3S$ requires C, 48.8; H, 4.4; N, 14.2%). When it was dissolved in acetic acid containing concentrated sulphuric acid and the solution poured into water it was converted into 4-nitro-5-acetamido-2-benzylthiazole (X1), which crystallised from ethanol in needles, m. p. 152° (Found : C, 52.5; H, 4.0; $C_{12}H_{11}O_3N_3S$ requires C, 52.0; H, 4.0%). 5-Acetamido-2-benzylthiazole (4 g.) in acetic anhydride (10 c.c.) and acetic acid (30 c.c.) containing fused sodium acetate (4 g.) and phosphoric oxide (0.5 g.) was cooled to 8°, and nitrosyl chloride in acetic acid added (0.5 hr.) until the red colour persisted. The mixture was allowed to stand at room temperature for 1 hour and was then poured into water (cf. France, Heilbron, and Hey, *J.*, 1940, 369). On standing, crystals separated, m. p. 135–140° raised to 152° on crystallisation from benzene and light petroleum (charcoal). 5-Acetamido-2-benzylthiazole (1.0 g.) was dissolved in acetic acid (10 c.c.) containing concentrated sulphuric acid (1 c.c.), and concentrated nitric acid (0.5 c.c.) added. After

30 hours at room temperature the mixture was poured into iced water, and the 4-nitrothiazole, m. p. 152°, collected. It was soluble in aqueous sodium hydroxide to give a red solution.

α -Aminobenzyl cyanide (1.3 g.) in ether (10 c.c.) was shaken with sodium dithioformate (1.0 g.) in water (10 c.c.) for 2 days. 5-Amino-4-phenylthiazole (0.7 g.) separated in colourless needles, m. p. 135–136°, and was recrystallised from benzene; a further quantity of crude material (0.4 g.) was recovered from the ether [Found : C, 61.6; H, 4.6; M (Rast), 170. $C_9H_8N_2S$ requires C, 61.4; H, 4.6%; M, 176]. The substance coupled with diazotised aniline in methanol solution containing sodium acetate. Treatment of a warm benzene solution of the base with acetic anhydride and addition of light petroleum (b. p. 40–60°) gave 5-acetamido-4-phenylthiazole, m. p. 147–148°, crystallising from benzene in sheaves of colourless needles (Found : C, 60.4; H, 4.7. $C_{11}H_{10}ON_2S$ requires C, 60.5; H, 4.6%). Solution of 5-amino-4-phenylthiazole in acetic acid and addition of a little ethanolic hydrogen chloride caused rapid separation of 5-amino-4-phenylthiazole hydrochloride (Found : C, 51.1; H, 4.1. $C_9H_8N_2S \cdot HCl$ requires C, 50.8; H, 4.2%). The compound crystallised from acetic acid in needles, m. p. 218° (decomp.), and gave a blue precipitate with sodium nitrite in aqueous solution.

Crude ethyl aminocynoacetate (ca. 5 g.) in ether (100 c.c.) was shaken with sodium dithioformate (4 g.) in water (50 c.c.), and the product kept overnight at 0°. The crystals recrystallised from ethanol to give 5-amino-4-carbethoxythiazole as prisms, m. p. 163.5° (Found : N, 16.3; S, 18.6. $C_6H_6O_2N_2S$ requires N, 16.3; S, 18.6%); the m. p. was undepressed by the product of desulphurisation of 5-amino-2-mercapto-4-carbethoxythiazole (Part II). The amine (0.5 g.) was boiled with acetic anhydride (0.5 c.c.) for 30 mins., and the solution poured on ice. 5-Acetamido-4-carbethoxythiazole crystallised from water in long needles, m. p. 123° (Found : C, 44.7; H, 4.4; S, 15.0. $C_8H_{10}O_3N_2S$ requires C, 44.9; H, 4.7; S, 15.0%).

Methyl ethylxanthate (1.4 g.) and morpholine (0.9 g.) were mixed. Heat and methylthiol were evolved and crystals separated. N-Monothiocarboethoxymorpholine was precipitated completely by adding ethanol and water, and recrystallised from aqueous ethanol or light petroleum in long needles, m. p. 58–59° (Found : C, 48.2; H, 7.4; N, 8.4. $C_7H_{13}O_2NS$ requires C, 48.0; H, 7.4; N, 8.0%).

[Received, January 23rd, 1947.]

319. Studies in the Azole Series. Part II. The Interaction of α -Amino-nitriles and Carbon Disulphide.

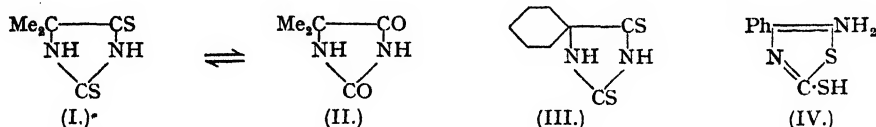

By A. H. COOK, SIR IAN HEILBRON, and A. L. LEVY.

The reaction between α -amino-nitriles and carbon disulphide leads, according to conditions, to 5-amino-2-mercaptothiazoles or derivatives thereof, or to dithiohydantoins. The former may be transformed into dithiohydantoins, or hydrolysed to α -amino-acids. The constitutions of representative compounds were confirmed by desulphurisation to 5-aminothiazoles or iminazoles. The further chemistry of 5-amino-2-mercapto-4-phenylthiazole (IV), in particular including its acetylation, methylation, condensation with aldehydes or ketones, and oxidation, is described, and some implications of these reactions are discussed.

THE preceding paper described the preparation and properties of 5-amino-2-benzylthiazole and some near derivatives. The preparative method, *viz.*, interaction of aminoacetonitrile and sodium or methyl dithiophenylacetate, promised to be of extensive application and the present communication deals with a detailed study of the reaction between α -amino-nitriles and carbon disulphide, which may be regarded as the anhydride of dithiocarbonic acid.

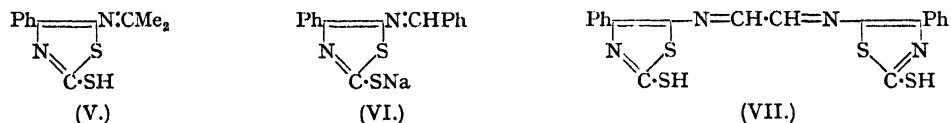

This reaction is stated (U.S.P. 2,143,816) to yield dithiohydantoins but the only example

described in detail is that with α -aminoisobutyronitrile. That the product was (I) was proved by oxidising it to the known 5:5-dimethylhydantoin which was reconverted into the thio-compound by heating with phosphorus pentasulphide (Henze and Smith, *J. Amer. Chem. Soc.*, 1943, **65**, 1090; cf. also Jacobson, *ibid.*, 1945, **67**, 1996). According to B.P. 512,629, *spirodithiohydantoin*s, e.g., (III), are similarly formed from amino-nitriles derived from cyclic ketones. It is interesting in view of these findings to recall that Bücherer and Lieb (*J. pr. Chem.*, 1934, **141**, 5) had, by analogy with the formation of hydantoins from carbon dioxide and moist α -amino-nitriles, unsuccessfully attempted the similar formation of dithiohydantoins.

Because of complications in the reaction between aminoacetonitrile and carbon disulphide, attention was first directed to the reaction between carbon disulphide and α -aminobenzyl cyanide; this base is easily accessible from benzaldehyde, hydrogen cyanide, and ammonia (Dubsy, *Ber.*, 1919, **52**, 232). The reaction was easily effected at room temperature, carbon disulphide being used in aqueous suspension. The product was a high-melting yellow crystalline solid, $\text{C}_9\text{H}_8\text{N}_2\text{S}_2$, which was obviously not 5-phenyl-2:4-dithiohydantoin. Contrary to this formulation it readily condensed with acetone to give a new compound, $\text{C}_{12}\text{H}_{12}\text{N}_2\text{S}_2$, which quickly reverted to the first material in presence of dilute mineral acid. This, together with other facts noted below, indicated that the primary product is more properly formulated as 5-amino-2-mercapto-4-phenylthiazole (IV), and the condensation product as the *Schiff's base* (V). It is interesting to note that the analogous benzaldehyde *Schiff's base* is formed in small yield by the direct interaction at room temperature of benzaldehyde, ammonium cyanide, and carbon disulphide in ethanol. The thiazole (IV) itself condensed equally easily with other aldehydes and ketones such as acetophenone and cinnamaldehyde to give yellow-orange, highly crystalline condensation products. All these bases were sensitive to mineral acid but more stable towards alkali, giving sparingly soluble sodium salts. Thus the benzaldehyde salt (VI) was obtained in yellow crystals, almost insoluble in water but soluble in ethanol, ethyl acetate, or acetone like metallic derivatives of dithiocarbamic acids to which they are obviously allied (cf. Delépine, *Bull. Soc. chim.*, 1908, **3**, 643).

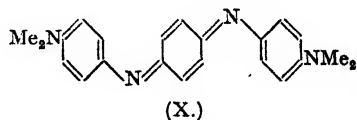

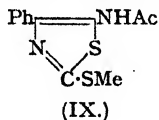

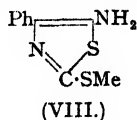

The chromophoric properties of the 5-aminothiazole system were particularly well illustrated by reaction of (IV) with glyoxal whereby the deep-red *bisazomethine* (VII) was readily formed; it gave a deep purple disodium salt soluble in acetone with an intense blue colour. Exactly similar red colours were observed on boiling (IV) in pyridine with diacetyl, phenylmethylglyoxal, or benzil, the colours in each case deepening considerably in presence of alkali. Condensation proceeded remarkably easily between the hydrochloride of (IV) and carbonyl compounds in cold methanol; in this way *Schiff's bases* derived from phenanthraquinone and isatin were also obtained.

Hydrolysis of (IV) under moderately vigorous acid conditions gave α -aminophenylacetic acid and carbon disulphide. It was weakly basic and pseudoacidic; it formed a *hydrochloride*, and when treated with methyl sulphate in an aqueous alkaline medium was converted into 5-amino-2-methylthio-4-phenylthiazole (VIII). Similar alkylation with benzyl chloride afforded 5-amino-2-benzylthio-4-phenylthiazole. Methylation was effected more easily by refluxing with methyl iodide in ethanol, the *hydriodide* of (VIII) being obtained. When the first method was used, a water-soluble methosulphate formed a by-product. This compound could still be diazotised and coupled with β -naphthol and is formulated as 5-amino-2-methylthio-4-phenylthiazole methosulphate. It condensed remarkably easily with compounds containing reactive methyl or methylene; for instance, on mixing with an aqueous solution of quinaldine methiodide, methylthiol was evolved and a cyanine dyestuff separated in purple crystals. This and similar reactions will be reported in detail in due course.

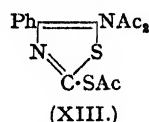

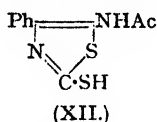

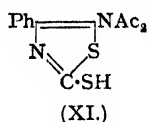

Diazotisation of (VIII) gave a diazonium salt solution which coupled readily with

5-amino-2-benzylthiazole to a deep red dye. Similarly, by using β -naphthol, the crystalline *azo-dye* was isolated. Condensation of (VIII) with glyoxal in ethanol gave the *SS'-dimethyl* derivative of (VII) which separated almost immediately as maroon crystals. A better reagent was a cold methanolic solution of the hydrochloride of (VIII), which reacted immediately with numerous carbonyl compounds (see experimental portion), to give the corresponding *Schiff's bases*. It may be mentioned that a colour with glyoxal under these conditions seems diagnostic of the presence of a 5-amino-2-mercaptothiazole. Acetylation of (VIII) gave 5-acetamido-2-methylthio-4-phenylthiazole (IX), also obtained by the action of alcoholic methyl iodide on 5-acetamido-2-mercapto-4-phenylthiazole (see below); (IX) was relatively stable to boiling sodium hydroxide and ethanolic hydrogen chloride.

Many attempts were made to condense 5-amino-2-mercapto-4-phenylthiazole (IV) with *p*-nitrosodimethylaniline, a variety of products being obtained under different conditions. Insofar as they were examined, however, the reaction seemed one of oxidation-reduction rather than condensation. For instance, in pyridine considerable heat was evolved and a deep red colour developed; analysis of the red-brown crystalline product agreed best, though not completely satisfactorily, with the *quinoneimine* (X). This formed a labile hydrochloride which on more prolonged treatment with ethanolic hydrochloric acid was converted into the bis-hydrochloride of *p*-aminodimethylaniline.

When (IV) was acetylated for a short time under mild conditions, an alkali-soluble monoacetyl derivative formulated as 5-acetamido-2-mercapto-4-phenylthiazole (XII) was obtained, though perhaps as a result of hydrolysis of the diacetyl derivative. More drastic treatment gave an alkali-labile diacetyl derivative regarded as 5-diacetylamino-2-mercapto-4-phenylthiazole (XI), and still more prolonged treatment gave a triacetyl derivative. Both di- and tri-acetyl derivatives reverted to (XII) on mild hydrolysis and the triacetyl compound must, it appears, be formulated as 5-diacetylamino-2-acetylthio-4-phenylthiazole (XIII).

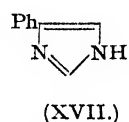

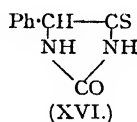

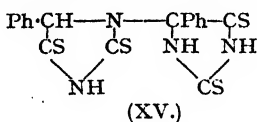

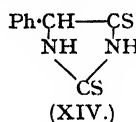

When (IV) was allowed to stand with alkaline hydrogen peroxide it was converted into a red sodium salt, from which the free compound was obtained as an orange pigment. Treatment of the sodium salt with methyl sulphate gave a non-acidic orange *dimethyl* derivative. Analyses suggested empirical formulae of the type $C_{38}H_{22}ON_6S_4$ and $C_{38}H_{26}ON_6S_4$ respectively for these products (*i.e.*, four thiazole nuclei with two methyl groups or methylatable hydrogen atoms) although the molecular weight of the methyl derivative in camphor seemed to be 306; there is as yet insufficient evidence to suggest detailed structures for these compounds. The same acidic product was formed on aerial oxidation of (IV) or with sodium nitroprusside in alkaline solution, and in surprisingly good yield by treating (IV) with alkali and acetylsulphanil chloride.

Many other colour reactions of the mercaptothiazole were observed; *e.g.*, intense red colours were developed on warming with benzoyl chloride or 2 : 4-dinitrochlorobenzene but the nature of the products was not investigated.

In view of the antibacterial activity of certain cyclic thiols (Gibbs and Robinson, *J.*, 1945, 925), the effect of (IV) was examined. At a concentration of 1 mg./c.c. in neutral phosphate buffer it showed considerable inhibition of the growth of *Staph. aureus*.

Convincing evidence of the correctness of the thiazole structures was afforded by treating (IV) and its derivatives with alkali and Raney nickel respectively. For example, when (IV) was brought into contact with the latter reagent in hot ethanol, removal of one atom of sulphur proceeded spontaneously to give the known 5-amino-4-phenylthiazole (Part I, preceding paper), which, unlike the parent mercapto-compound, gave no characteristic colours with glyoxal. The base was also obtained by desulphurising the corresponding acetone or benzaldehyde *Schiff's bases* of (IV), and the acetyl derivative was smoothly prepared by desulphurising 5-acetamido-2-mercapto-4-phenylthiazole.

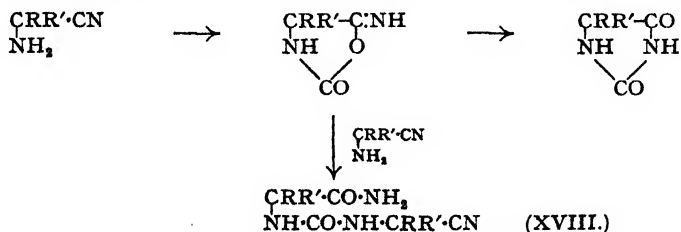

When (IV) was boiled with aqueous ammonia the solution soon ceased to give the characteristic Schiff's base with glyoxal, and an isomeride of the original base was isolated; from results described below this is formulated as 2:4-dithio-5-phenylhydantoin (XIV). The same dithiohydantoin was obtained by treatment of (IV) with caustic alkali, together with 1':5-bis-(2:4-dithio-5-phenylhydantoin) (XV). The latter structure is assigned by analogy with diphenylhydantoin, formed by the action of alkali on 5-phenylhydantoin (Pinner, *Ber.*, 1888, 21, 2320; Gabriel, *Annalen*, 1906, 250, 118). (XV) was more readily obtained by the action of mild oxidising agents on the dithiohydantoin. Treatment of 5-amino-2-methylthio-4-phenylthiazole (VIII) with alkali led to elimination of methylthiol and formation of 4-thio-5-phenylhydantoin (XVI) with the same properties as that described by Johnson and Chernoff (*J. Amer. Chem. Soc.*, 1912, 34, 1212). The structure of (XIV) was indicated by its pseudoeidic and non-basic character and especially by its behaviour with Raney nickel. By contrast with the parent thiazole (IV) both sulphur atoms were labile, the product being 5(4)-phenyliminazole (XVII), also obtained from (XV) by similar means. Further examples of this facile synthesis of iminazoles of more general interest will be described in later communications. An attempt was made to synthesise (XIV) by the action of phosphorus pentasulphide on 5-phenylhydantoin, but surprisingly the product proved to be 5(4)-phenyliminazole (XVII). Both (XIV) and (XV) were remarkably stable to acid and alkaline hydrolysis, more so than their oxygen analogues.

When α -aminopropionitrile was treated with carbon disulphide under conditions comparable with those in the foregoing experiments, two products were obtained in approximately equal yield. One was a pseudo-acid with no observable basic properties and is probably to be formulated as 2:4-dithio-5-methylhydantoin. The second product evolved acetaldehyde on warming with mineral acid and is regarded as the *acetaldehyde Schiff's base* of 5-amino-2-mercapto-4-methylthiazole, treatment with hydrogen chloride giving 5-amino-2-mercapto-4-methylthiazole *hydrochloride* characterised by the scarlet colour with glyoxal. The formation of the acetaldehyde Schiff's base is clearly similar to that of the corresponding phenyl compound described above. Indeed, when the present reaction was deliberately carried out in presence of acetaldehyde, dithiohydantoin formation was completely inhibited and the aminothiazole derivative was the sole product.

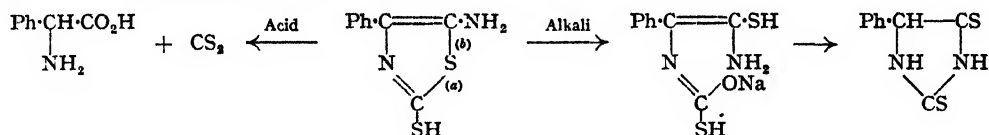

On similar reaction of ethyl aminocynoacetate (cf. preceding paper) a product was easily isolated which although failing to diazotise under normal conditions did so in concentrated sulphuric acid solution and must be formulated as 5-amino-2-mercapto-4-carbethoxythiazole. This was confirmed by treatment with Raney nickel, whereby it was converted into 5-amino-4-carbethoxythiazole, identified with the material described in the preceding paper. When the condensation with carbon disulphide was carried out in acetone solution an unstable intermediate, probably the acetone Schiff's base, was obtained which passed into the above aminomercaptocarbethoxythiazole on recrystallisation.

The above examples indicate therefore a general reaction leading to aminothiazoles or dithiohydantoins according to conditions. It is possible, moreover, that analogous reactions take place between α -amino-nitriles and carbon dioxide, for a facile combination of carbon dioxide and α -aminobenzyl cyanide was observed, giving a surprisingly stable *product* having a composition corresponding to $(\text{C}_6\text{H}_5\text{N}_2)_2\text{CO}_2$. Bucherer and Steiner (*J. pr. Chem.*, 1934, 140, 291) observed that the interaction of carbon dioxide and α -aminoisobutyronitrile led to 5:5-dimethylhydantoin together with a second product tentatively regarded as (XVIII); R, R' = Me).

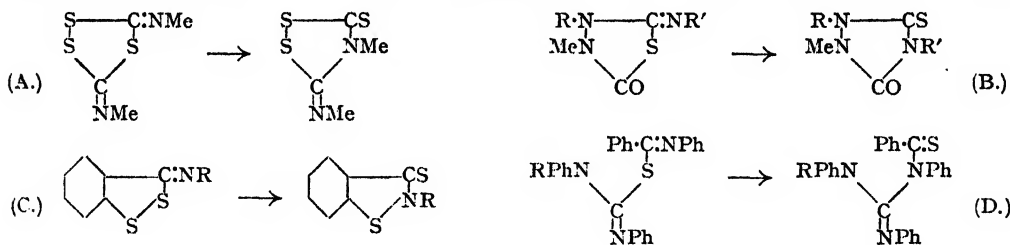

The genesis of both products is readily understood if the formation of an imino-oxazolidone as an intermediate comparable with the above aminothiazoles be assumed. In this case the product from α -aminobenzyl cyanide is best regarded as (XVIII; R = H, R' = Ph). The rearrangement of the imino-oxazolidone to the hydantoin may be compared with the transformation of *o*-cyanobenzoic acid into phthalimide presumably *via* an imino-compound (Sandmeyer, *Ber.*, 1885, 18, 1499).

It will be noticed that in the above examples an aminothiazole was obtained in the case of the reactions with α -aminobenzyl cyanide or ethyl aminocynoacetate and that in the former instance a medium such as alkali or moist pyridine was required to complete the transformation into the dithiohydantoin. This reflects a stabilising influence of the phenyl and the carbethoxyl group on the thiazole ring and, secondly, suggests that the mechanism of the transformation consists first in fission of the bond (a) :

The closely analogous cyclisation of α -carbethoxyaminophenylthioacetamide in alkali to 4-thio-5-phenylhydantoin (XVI) has been described by Johnson and Chernoff (*loc. cit.*). When 5-amino-2-mercapto-4-phenylthiazole was boiled, on the other hand, with dilute mineral acid, α -aminophenylacetic acid and carbon disulphide were formed indicating fission at (b) which may be preceded by elimination of ammonia. This indirect hydrolysis of an α -amino-nitrile has been applied to the preparation of more complicated α -amino-acids which will be described elsewhere. The process offers advantages in that the aminothiazole derivatives are more readily isolated and crystallise easily compared with α -amino-nitriles.

The above transformation into a dithiohydantoin presents no essential novelty, being paralleled in other heterocyclic series of varying complexity. Thus the transformation (A) was noted by Freund (*Annalen*, 1895, 285, 154), (B) by Busch and Limpach (*Ber.*, 1911, 44, 560),

and (C) by McClelland and Salkeld (*J.*, 1936, 1143). The observation of "acyclic" transformations of this kind, of which (D) is a recent example (Rivie and Langer, *Helv. Chim. Acta*, 1943, 26, 1722), points to a probable oversimplification in the mechanism suggested under (a) above.

The absorption spectra of most of the above thiazoles are tabulated below. A practically invariable feature is a band at *ca.* 2900 Å. which reflects a strong bathochromic effect of the 5-amino-grouping, as thiazoles and alkylthiazoles exhibit a band at *ca.* 2400 Å. (Ruehle, *J. Amer. Chem. Soc.*, 1935, 57, 1887; Jones, Robinson, and Strachan, *J.*, 1946, 91).

EXPERIMENTAL.

Reactions with α -Aminobenzyl Cyanide.—Redistilled benzaldehyde (367 g.) was mixed with anhydrous hydrogen cyanide (103 g.), and aqueous ammonia (*d* 0.880, 1—2 c.c.) added to initiate the reaction, which was moderated by strong cooling. After the mixture had stood at room temperature for 7 hours, liquid ammonia (65 g.) dissolved in ethanol (150 c.c.) was added and the mixture stood for 1 day at room temperature and 2 days at 0°. The large plates of α -aminobenzyl cyanide (115 g.) which had separated were filtered off and washed with plain spirit (500 c.c.); m. p. 55°. The syrupy filtrate was treated with carbon disulphide (200 c.c.), and large yellow crystals (126 g.) of the thiazole (see below) were soon deposited. This crude product (m. p. 259°, decomp.) contained about 8% of the corresponding benzylidene derivative, which can be removed as its insoluble sodium salt by treatment with aqueous sodium hydroxide.

α -Aminobenzyl cyanide (13.5 g.) was refluxed in ether (250 c.c.) with carbon disulphide (10 g.) for 8 hours. The yield of yellow crystals (12.8 g.) was augmented by standing the filtrate with carbon

disulphide (10 g.) overnight (total yield, 19.6 g., 93%). In another preparation the nitrile (20 g.) in ether (500 c.c.) was kept with carbon disulphide (11 c.c.) for 2½ days, and the crystals (26 g.) collected; on longer standing a further 4 g. separated (total yield, 95%).

α -Aminobenzyl cyanide hydrochloride (1.0 g.) in water (10 c.c.) was neutralised to phenolphthalein with 2*N*-sodium hydroxide, and carbon disulphide (0.5 c.c.) and a little methanol added. After 17 hrs.' shaking at room temperature, crude 5-amino-2-mercapto-4-phenylthiazole (IV) (0.65 g.) was obtained. This was sparingly soluble in ethanol, from which it separated in bright yellow tablets, and in most common solvents, but crystallised well from pyridine-ethanol in needles, and then had m. p. 261–262° (decomp.) (Found : C, 52.3; H, 3.9. $C_9H_8N_2S_2$ requires C, 51.9; H, 3.9%). It was converted into a very insoluble product in boiling nitrobenzene but dissolved in alkali and was precipitated unchanged by acid; it was soluble in aqueous baryta, a barium salt soon crystallising in plates. The thiazole dissolved in concentrated sulphuric acid to a lemon-yellow solution and deposited a chocolate-brown precipitate on dilution. Treatment with benzoyl chloride or 2 : 4-dinitrochlorobenzene in dioxan gave an intense red colour.

The thiazole (IV) was shaken with ethanolic hydrogen chloride. After about 1 hour the flask was filled with a thick cream of hydrochloride. 5-Amino-2-mercapto-4-phenylthiazole hydrochloride could be recrystallised from ethanol-etheral hydrogen chloride but crystallised best from methanol on adding concentrated hydrochloric acid; it formed colourless needles, m. p. 189° (decomp.) (Found : C, 44.0; H, 4.0; N, 11.1. $C_9H_8N_2S_2Cl$ requires C, 44.2; H, 3.7; N, 11.4%).

The thiazole (IV) was refluxed with excess of acetone. After 1 hour a clear solution was obtained which was evaporated in a vacuum and the residue taken up in ethanol. On cooling, the Schiff's base (V) separated in pale yellow needles, m. p. 187°, in almost theoretical yield (Found : C, 58.2; H, 5.1; N, 10.9. $C_{12}H_{12}N_2S_2$ requires C, 58.1; H, 4.8; N, 11.3%). The same product (1 g.) was obtained when α -aminobenzyl cyanide (1 g.) was refluxed with carbon disulphide (5 c.c.) and acetone (20 c.c.) for 3 hours, and the solution evaporated until it crystallised. 5-Amino-2-mercaptothiazole was refluxed overnight in ethanol with an excess of acetophenone. On filtering and cooling an excellent yield of the acetophenone Schiff's base crystallised. It could be recrystallised from ethanol containing dioxan in yellow needles, m. p. 212° (Found : C, 65.5; H, 4.2; N, 8.6. $C_{17}H_{14}N_2S_2$ requires C, 65.8; H, 4.5; N, 9.0%); it was also formed, though in poorer yield, on boiling the components in pyridine. The aminothiazole (IV) (2 g.) was refluxed with ethanol (50 c.c.) and cinnamaldehyde (2 g.) for 5 mins., the contents of the flask then having set almost solid with a mass of orange crystals (2.7 g.). The cinnamaldehyde Schiff's base was insoluble in ethanol, moderately soluble in hot toluene, chloroform, acetone, or ethyl acetate, from which it crystallised in needles, or in acetic acid from which it separated in spear-shaped crystals. It was best crystallised from ethanol-dioxan (2 : 1) in orange needles; m. p. 226° (Found : C, 68.6, 66.6; H, 4.5, 4.9; N, 8.9. $C_{18}H_{14}N_2S_2$ requires C, 67.1; H, 4.4; N, 8.7%). It gave a red crystalline sodio-derivative crystallising from aqueous ethanol, and an intense red colour with ethanolic hydrogen chloride or concentrated sulphuric acid, but dilute acid quickly hydrolysed it to its components.

The benzaldehyde Schiff's base, which could be prepared in the usual manner, crystallised from ethanol containing a little water in fine yellow needles, m. p. 226–229° (slow heating) after contracting at 205° (Found : C, 65.0; H, 4.1; N, 9.55. $C_{16}H_{12}N_2S_2$ requires C, 64.9; H, 4.1; N, 9.5%). Benzaldehyde (10.5 g.) in ethanol (50 c.c.) was kept over-night with ammonium cyanide (4.5 g.) and carbon disulphide (8 g.). The Schiff's base (4.0 g.) separated and a further 2.5 g. separated after 1 week. The benzaldehyde Schiff's base dissolved in 2*N*-sodium hydroxide to a lemon-yellow solution which on standing deposited a yellow solid. This sodium salt (VI) was soluble in acetone, ethanol, or ethyl acetate and was purified by extraction with acetone and precipitation with light petroleum or by crystallisation from aqueous sodium hydroxide, then separating in jagged yellow laths having a pearly lustre, m. p. 298° (Found : C, 52.0; H, 4.7; N, 7.7. $C_{16}H_{11}N_2S_2Na \cdot 3H_2O$ requires C, 51.6; H, 4.6; N, 7.5%); it gave the original mercapto-compound on acidification.

5-Amino-2-mercapto-4-phenylthiazole (IV) (2 g.) in 2*N*-sodium hydroxide (6 c.c.) diluted to 25 c.c. was treated with 50% glyoxal (1.5 c.c.) in water (5 c.c.). An intense purple colour appeared immediately, heat was evolved, and a sodium salt soon separated. The salt was suspended in hot water (100 c.c.) and acidified to give the free condensation product; more was obtained from the filtrate from the sodium salt (total yield 1.8 g.). The bisazomethine compound (VII) was practically insoluble in ethanol, acetic acid, dioxan, toluene, and other solvents but crystallised from pyridine-ethanol in sheaves of purple needles, m. p. 292–293° (decomp.) (Found : C, 55.0; H, 3.4. $C_{20}H_{14}N_4S_4$ requires C, 54.8; H, 3.2%). It was soluble in alcoholic ammonia to a purple solution which became deep blue in acetone, the sodium salt also giving a blue solution with acetone. The colour was observed also in pyridine but not in dioxan, ethanol, ethyl acetate, or diethylamine.

5-Amino-2-mercapto-4-phenylthiazole (IV) (2 g.), acetic anhydride (10 c.c.), and 1 drop of concentrated sulphuric acid were refluxed for 3 minutes and solvent removed in a vacuum. The crystalline residue was dissolved in hot ethanol (15 c.c.). On cooling, the crystals (0.7 g.), m. p. 162–163°, were collected, and a second crop (1.5 g.), m. p. 148–158°, isolated from the mother-liquor (this material consisted mainly of the diacetyl derivative and on crystallisation from aqueous ethanol the m. p. rose considerably). The solid in the minimum of acetone-benzene (1 : 3) was chromatographed on alumina and eluted with 10% and ultimately with 90% acetone in benzene. The material from 10 fractions was substantially homogeneous (m. p. 244–247°). It was insoluble in hydrocarbons, chloroform, ethyl acetate, ether, or water, but soluble in hot ethanol, acetone, or acetic acid. 5-Acetamido-2-mercapto-4-phenylthiazole (XII) separated from ethanol in colourless needles, m. p. 244–245° (Found : C, 53.1; H, 4.0; N, 10.9. $C_{11}H_{10}ON_2S_2$ requires C, 52.8; H, 4.0; N, 11.2%), which dissolved immediately in alkali. In a larger preparation 5-amino-2-mercapto-4-phenylthiazole (30 g.) was heated to boiling with acetic anhydride (100 c.c.), and the clear solution poured into water (11.). The precipitated oil rapidly granulated and was dissolved in sufficient warm 2*N*-sodium hydroxide and precipitated with concentrated hydrochloric acid from a total volume of 21. The product (35.5 g.), after being washed and dried at 100°, had m. p. 244° (decomp.). The parent aminothiazole (IV)

(1 g.) was refluxed for 5 mins. with acetic anhydride (5 c.c.). On cooling, the solid was collected and washed with ether, more being obtained from the filtrate on adding light petroleum (total yield, 1.15 g.). 5-Diacetylamino-2-mercapto-4-phenylthiazole (XI) recrystallised best from acetic anhydride in prismatic needles, m. p. 166° (Found: C, 53.2; H, 4.2. $C_{13}H_{11}O_4N_2S_2$ requires C, 53.4; H, 4.1%); it dissolved (0.5 min.) in cold 2N-sodium hydroxide, the preceding monoacetyl derivative being recovered on acidification, and hydrolysis also took place slowly on exposure to air. The parent aminothiazole (IV) (2 g.) was warmed for 45 mins. at 100° with acetic anhydride (10 c.c.) containing a little sulphuric acid, and the solution finally refluxed for 3 mins. and evaporated in a vacuum. The residue crystallised and was recrystallised (yield 0.9 g.) from ethanol to give the triacetyl derivative (XIII) as prisms, m. p. 132° (Found: C, 54.0; H, 4.3; N, 8.5. $C_{15}H_{11}O_6N_2S_2$ requires C, 53.9; H, 4.2; N, 8.4%). This compound also reverted to the N-monoacetyl compound on mild hydrolysis.

5-Amino-2-mercapto-4-phenylthiazole (IV) (10 g.) in 2N-sodium hydroxide (20 c.c.) was stirred with chloroform (50 c.c.) and methyl sulphate (5 c.c.) dropped in during 5 mins. Acidification of the aqueous layer gave unchanged starting material (1 g.). Evaporation of the chloroform layer and addition of alcoholic hydrogen chloride gave 5-amino-2-methylthio-4-phenylthiazole hydrochloride, which crystallised from ethanol in magnificent, pale yellow needle clusters, m. p. 175° (decomp.) (Found: C, 46.3; H, 4.3; N, 10.6. $C_{10}H_{11}N_2S_2Cl$ requires C, 46.4; H, 4.3; N, 10.8%). The crude free base obtained from the chloroform solution above was mixed with a small excess of acetic anhydride; heat was evolved and the mixture solidified. 5-Acetamido-2-methylthio-4-phenylthiazole (IX) crystallised from ethanol in well-formed needles, m. p. 168° (Found: C, 54.9; H, 4.6; N, 10.4. $C_{12}H_{13}ON_2S_2$ requires C, 54.6; H, 4.6; N, 10.6%). The compound was still a base, affording a crystalline hydrochloride with hydrogen chloride in ethyl acetate.

In a larger methylation experiment (41.6 g. of aminomercapto-compound) the chloroform was evaporated and the semi-crystalline residue treated with ethyl acetate to give 5-amino-2-methylthio-4-phenylthiazole methosulphate (5.0 g.), which crystallised best from *tert*-butanol in long needles, m. p. 123° (Found: C, 41.0; H, 5.0; N, 8.0. $C_{12}H_{13}O_4N_2S_2$ requires C, 41.4; H, 4.6; N, 8.0%). The compound was water-soluble, and reaction with aqueous quinaldine methiodide containing 1 equiv. of sodium hydroxide gave a deep purple precipitate; no colouration was obtained with glyoxal. The substance was biologically inactive towards *Staph. aureus* in 0.2% phosphate buffer (pH 7). The corresponding *picrate* crystallised from acetic acid in needles, m. p. 202° (Found: C, 44.3; H, 3.4; N, 14.9. $C_{11}H_{10}O_7N_2S_2$ requires C, 43.9; H, 3.2; N, 15.0%). The ethyl acetate filtrate (above) was evaporated, and the residue in ether run on to an alumina column and developed with 20% ether in light petroleum. The eluates yielded 5-amino-2-methylthio-4-phenylthiazole (VIII), which crystallised from light petroleum (b. p. 80–100°) in colourless needles, m. p. 70–71° (Found: C, 54.0; H, 5.0; N, 12.8. $C_{10}H_{10}N_2S_2$ requires C, 54.0; H, 4.5; N, 12.6%).

5-Amino-2-mercapto-4-phenylthiazole (IV) (2 g.) was refluxed with methyl iodide (1.5 g.) in ethanol (10 c.c.) for 0.5 hour. On cooling, a mass of pale needles separated (2.7 g.), which recrystallised from ethanol to give 5-amino-2-methylthio-4-phenylthiazole hydriodide, m. p. 172° (decomp.) (Found: C, 34.5; H, 3.5. $C_{10}H_{11}N_2S_2I$ requires C, 34.3; H, 3.14%).

5-Acetamido-2-mercapto-4-phenylthiazole (XII) (34 g.) was refluxed with methyl iodide (20 g.) in ethanol (200 c.c.) for 10 minutes, the reaction being exothermic. Pyridine (10 c.c.) was added, and the mixture cooled to yield 5-acetamido-2-methylthio-4-phenylthiazole (IX) (37 g.), m. p. 162–210°; dilution of the filtrate with water gave a second crop (8.5 g.), m. p. 167°. The combined crops were recrystallised from ethanol (250 c.c.) to yield the pure thiazole above, m. p. 168°.

α -Aminobenzyl cyanide (2.6 g.), benzyl chloride (2.5 g.), and carbon disulphide (1.5 g.) were kept at room temperature in pyridine (10 c.c.) for 18 hours. The solvent was evaporated in a vacuum, and the syrupy residue treated with water (20 c.c.) and ether (20 c.c.); a small quantity of 5-amino-2-mercapto-4-phenylthiazole separated and was removed by filtration. The ether was washed successively with 2N-sodium hydroxide (20 c.c.), 2N-hydrochloric acid (10 c.c.), and water (20 c.c.) and dried and evaporated to yield 5-amino-2-benzylthio-4-phenylthiazole, m. p. 107° (Found: C, 65.0; H, 5.0; N, 9.2; S, 21.4. $C_{16}H_{14}N_2S_2$ requires C, 64.4; H, 4.7; N, 9.2; S, 21.5%). The compound crystallised best from cyclohexane, and lost benzylthiol on treatment with aqueous alkali. It readily condensed with glyoxal to give a scarlet Schiff's base and could be diazotized in acid solution.

5-Amino-2-methylthio-4-phenylthiazole hydrochloride (2.5 g.), dissolved in acetic acid (25 c.c.) containing concentrated sulphuric acid (2 c.c.), was cooled in a freezing mixture, and treated during 5 minutes with N-sodium nitrite (10 c.c.). After standing in ice for a further 10 minutes, the diazotised base was added to a solution of β -naphthol (1.4 g.) in ethanol (40 c.c.) and water (10 c.c.) containing saturated aqueous sodium acetate (10 c.c.), and the precipitated dye collected. Extraction with hot ethanol followed by solution in warm benzene and precipitation with light petroleum (b. p. 40–60°) gave 2-methylthio-4-phenylthiazole-5-azo- β -naphthol (1.5 g.), which crystallised from ethyl acetate in long red needles, m. p. 170–171°, and gave an intense blue solution in concentrated sulphuric acid (Found: C, 63.2; H, 4.2; N, 11.3. $C_{20}H_{15}ON_3S_2$ requires C, 63.6; H, 4.0; N, 11.1%).

5-Amino-2-methylthio-4-phenylthiazole (VIII) (1.7 g.) in cold ethanol (30 c.c.) was treated with 50% glyoxal (3 c.c.) in ethanol (10 c.c.). A scarlet colour and crystalline precipitate appeared within 20 secs. The solution was heated to boiling and filtered hot (yield, 0.7 g.). The *azomethine* compound was insoluble in ethanol, acetic acid, or ethyl acetate, moderately soluble in hot chloroform, benzene, or toluene, and crystallised from benzene containing a little light petroleum in needles, m. p. 242–243° (decomp.). The compound appeared to form a labile brown hydrochloride, dissolved in concentrated sulphuric acid to a purple solution, and was apparently stable to boiling 2N-sodium hydroxide.

In another preparation of this and other methylated Schiff's bases equivalent proportions of the carbonyl compound and 5-amino-2-methylthio-4-phenylthiazole hydrochloride were mixed in cold methanol, and the condensation product crystallised in almost quantitative yield. The results are summarised in the following table. This method was also most convenient for preparing the mercapto-Schiff's bases from 5-amino-2-mercapto-4-phenylthiazole hydrochloride, and the last two entries in the table are examples of its use.

Carbonyl component.	M. p. and colour.	Recryst. from : *	Formula.	Analysis.

* A = ethanol; B = acetic acid; C = benzene; D = ethyl acetate; E = pyridine.

5-Amino-2-mercapto-4-phenylthiazole (IV) (5 g.) and *p*-nitrosodimethylaniline (5 g.) were warmed in pyridine (25 c.c.) to initiate the exothermic reaction. Evaporation and addition of water-ethanol (1 : 4, 40 c.c.) gave red-brown crystals which were recrystallised in similar manner or from light petroleum and then had m. p. 92°; this is probably the *quinoneimine* (X) (Found : C, 77.1; H, 7.4. C₂₂H₁₂N₄ requires C, 77.5; H, 6.4%). On rapid treatment with ethanolic hydrogen chloride a labile hydrochloride was obtained, but longer treatment (at room temp. for 10 mins.) followed by addition of ether gave *p*-aminodimethylaniline dihydrochloride, m. p. 208° (decomp.) (lit. m. p. 218°) (Found : C, 46.6; H, 6.9; N, 12.7. Calc. for C₈H₁₀N₂Cl₂ : C, 46.0; H, 6.7; N, 13.4%). It gave known colour reactions with ferric chloride, sodium nitrite, sodium nitroprusside, hydrogen peroxide, alkaline ferricyanide, and iodine in potassium iodide, and the methylene-blue reaction with hydrogen sulphide followed by ferric chloride.

Oxidation Experiments.—5-Amino-2-mercapto-4-phenylthiazole (IV) was oxidised in aqueous alkali under a variety of conditions, forming an insoluble, red, crystalline, sodium salt, and a number of other more complex green oxidation products which have not been investigated. Hydrogen peroxide, oxygen, potassium ferricyanide, sodium nitroprusside, and benzoquinone all gave red and green products, though the proportion seemed to vary with the oxidising agent employed. None of the simple disulphide was isolated in these experiments, though there is evidence that it was formed in acid solution.

In a typical large-scale experiment, the aminothiazole (15 g.) was dissolved in 2*N*-sodium hydroxide (40 c.c.), and oxygen passed through the solution for 16 hours. The red needle crystals (1.8 g.) which were precipitated were filtered off, washed with a little water and dried. They decomposed at 277—278° and contained sodium. Solution in ethanol, acetone, ethyl acetate, dioxan, or pyridine was very ready, and the material could be crystallised from these solvents by adding ether or light petroleum. Crystallisation was best effected, however, from warm water, in which the salt was readily soluble. In all but acetone and pyridine the solutions were deep red, but in these two solvents the reagent colour was very similar to the rhodamines, showing also a violet fluorescence (cf. behaviour of sodium salt of glyoxal Schiff's base). Addition of other metallic ions to the aqueous sodium salt solution caused precipitation of crystalline and highly coloured metallic derivatives; e.g., the barium salt melted at 267—270° and crystallised beautifully from hot aqueous ethanol. Acidification of the sodium salt caused precipitation of the free acid (see below) as light orange needles, m. p. 241°. 5-Amino-2-mercapto-4-phenylthiazole (IV) (2 g.) in 2*N*-sodium hydroxide (12 c.c.) was treated with acetylsulphanil chloride (2 g.), producing an intense purple colour which later became green. After being shaken for 1 hour at room temperature, the mixture was filtered, and the insoluble material (0.95 g.) purified by recrystallisation from warm sodium carbonate solution, forming deep red needles, m. p. 268—269°, identical with the above sodium salt.

The sodium salt (1.8 g.) was dissolved in hot water (200 c.c.) and filtered from a little insoluble material. Sodium hydrogen carbonate solution (20 c.c.) was added, followed by chloroform (100 c.c.), and methyl sulphate was dropped into the well-stirred mixture until the intense colour had passed from the aqueous to the organic layer. The mixture was filtered from some orange material (substance A) which had separated during the reaction and the chloroform was separated, washed, dried, and evaporated to yield a mass of dark crystals. These were washed with ether which removed most of the colour, leaving a yellow substance which crystallised well from hot ethanol in needles, m. p. 128° [Found : C, 64.5; H, 3.9; N, 11.7; M (Rast), 306. C₂₀H₁₆ON₂S₄ requires C, 64.2; H, 3.7; N, 11.8%; M, 710]. Light absorption (chloroform) : $\lambda_{\max.} = 265, 282, 327, 450 \text{ m}\mu$; $E_{1\%}^{1\text{cm.}} = 525, 525, 320, 820$.

Substance A melted at 239—240°, and was identical with the free acid. It was insoluble in both hot and cold water, ether, alcohol, acetic acid, and toluene, sparingly soluble in hot ethyl acetate and chloroform, and readily soluble in acetone, dioxan, and pyridine on gentle warming. However, crystallisation proved difficult; use of mixed solvents in the cold caused either too rapid precipitation or none, and prolonged heating with acetic acid or aqueous dioxan caused decomposition into alkali-insoluble materials, and yellow materials soluble or insoluble in alkali according to conditions. These degradation products were not further investigated. The compound crystallised best from a large volume of hot chloroform in small orange needles, m. p. 239—240° (Found : C, 62.9; H, 3.4; N, 12.1. C₂₀H₁₆ON₂S₄ requires C, 63.3; H, 3.3; N, 12.3%). Light absorption (dioxan) : $\lambda_{\max.} = 223, 260, 270, 315, 450 \text{ m}\mu$. $E_{1\%}^{1\text{cm.}} = 400, 500, 400, 400$.

5-Amino-2-mercapto-4-phenylthiazole (IV) (10 g.) and Raney nickel (24 g.) were suspended in ethanol (120 c.c.) and the mixture heated to boiling, after which the heat of reaction caused spontaneous refluxing. When reaction was complete the mixture was cooled, filtered from nickel sulphide, and evaporated in a vacuum. The brown semicrystalline residue possessed an amine-like odour and gave an intense green fluorescence in ethanol, probably due to small amounts of 2 : 2'-bisthiazoles (Karrer and Sanz, *Helv. Chim. Acta*, 1944, 27, 619). It was dissolved in benzene and chromatographed on alumina; development and elution with this solvent gave, on evaporation, 5-amino-4-phenylthiazole, m. p. 135–136°. Continued elution with 20% acetone in benzene yielded a further quantity of the aminothiazole, best isolated as the hydrochloride. This substance did not give a red Schiff's base with methanolic glyoxal. 5-Acetamido-2-mercapto-4-phenylthiazole (XII) (0.5 g.) and Raney nickel (1.2 g.) were suspended in ethanol (20 c.c.), and the mixture refluxed for 10 minutes. Nickel sulphide was removed by filtration, and evaporation in a vacuum gave 5-acetamido-4-phenylthiazole, m. p. 147–148°. The reaction was cleaner than with the parent amine. The benzaldehyde Schiff's base of 5-amino-2-mercapto-4-phenylthiazole (1.0 g.) and Raney nickel (3 g.) were refluxed in ethanol (20 c.c.) for 15 minutes. After filtration and evaporation in a vacuum a rather poor yield of 5-amino-4-phenylthiazole hydrochloride, m. p. 216° (decomp.), was obtained by treating the residue with ethereal hydrogen chloride containing a little ethanol. The acetone Schiff's base of 5-amino-2-mercapto-4-phenylthiazole (V) (0.5 g.) and Raney nickel (3 g.) were refluxed in ethanol (15 c.c.) for 15 minutes. Filtration and evaporation gave, on rubbing with benzene, 5-amino-4-phenylthiazole m. p. 135–136°.

5-Amino-2-mercapto-4-phenylthiazole (IV) (5 g.) was moistened with ethanol and boiled with 2N-hydrochloric acid (50 c.c.) for 1.5 hours. No hydrogen sulphide was produced, but an oily liquid was formed which was distilled out and collected in methanol containing some α -aminobenzyl cyanide. The solution, on standing for a day, deposited yellow crystals of 5-amino-2-mercapto-4-phenylthiazole (IV), m. p. 261°, together with a small quantity of red, alkali-soluble crystals, m. p. 272–273°. Essentially, therefore, the sulphur is split out as carbon disulphide. The hydrolysate was filtered from some insoluble material (0.7 g.; a mixture of unreacted thiazole and an orange-brown substance) and evaporated to dryness. The residue was treated with acetone to give colourless rods of α -aminophenylacetic acid hydrochloride (2.7 g.). Recrystallised from 18% hydrochloric acid it had m. p. 212° (decomp.); mixed m. p. with authentic material, 209° (decomp.). Treatment with potassium acetate solution gave the free base, subliming at 285–290°; authentic α -aminophenylacetic acid sublimed at 281–283°.

5-Amino-2-mercapto-4-phenylthiazole (IV) (20 g.) was boiled with 2N-sodium hydroxide (100 c.c.) for 1 hour. The solution, which now failed to give a scarlet Schiff's base with glyoxal, was diluted with water (600 c.c.), and the product precipitated by 2N-hydrochloric acid (200 c.c.) was extracted with boiling acetic acid (300 c.c., 300 c.c., 200 c.c.). The orange residue (4 g.) was insoluble in all common solvents except pyridine and was crystallised from alcoholic potash by addition of acetic acid to give 1' : 5-bis-(2 : 4-dithio-5-phenylhydantoin) (XV), m. p. 270–271° (decomp.) (Found : C, 51.8; H, 3.15; N, 13.6. $C_{18}H_{14}N_4S_4$ requires C, 52.2; H, 3.4; N, 13.5%). The acetic acid filtrates were cooled to 0° and the 2 : 4-dithio-5-phenylhydantoin (XIV) which separated (10.5 g.) was recrystallised rapidly from acetic acid, forming colourless clusters of stout needles, m. p. 264–265° (decomp.) (Found : C, 51.9, 52.5; H, 4.3, 3.8. $C_8H_8N_2S_2$ requires C, 51.9; H, 3.9%). This substance readily darkened on exposure to air or undue heating in solvents. It was soluble in pyridine and dioxan on gentle warming, moderately soluble in hot acetic acid, sparingly soluble in hot ethanol, and insoluble in other common solvents.

5-Amino-2-mercapto-4-phenylthiazole (IV) (1 g.) was boiled gently in aqueous ammonia (d 0.880) for 2 hours, a sufficient concentration of ammonia being maintained to keep the thiazole in solution. The ammonia was then boiled off, and after filtration from unreacted mercaptothiazole, the solution was acidified to yield 2 : 4-dithio-5-phenylhydantoin (XIV), m. p. 264–265° (decomp.). 5-Amino-2-mercapto-4-phenylthiazole (IV) (5 g.) was refluxed in pyridine (20 c.c.) for 15 minutes; some hydrogen sulphide was evolved and the solution became deep red. On cooling, a mass of deep red crystals was produced, which could be recrystallised from pyridine, and melted at about 75°. On exposure to air for 10 minutes, or treatment with ethanol or water, the material fell to an insoluble orange powder, m. p. 270–271°, identical with 1' : 5-bis-(2 : 4-dithio-5-phenylhydantoin) (XV). The same result was obtained when 2 : 4-dithio-5-phenylhydantoin (XIV) was substituted for the aminothiazole in the above experiment. The deep red crystals were not produced, however, when a saturated pyridine solution of the bisdithiohydantoin (XV) was cooled. 5-Amino-2-methylthio-4-phenylthiazole hydriodide (1 g.) was refluxed with 2N-sodium hydroxide (20 c.c.) for 0.5 hour. The solution was filtered from a little unsaponified material and acidified with concentrated hydrochloric acid. Methylthiol was evolved and yellow granular crystals of 4-thio-5-phenylhydantoin (XVI) were precipitated, m. p. 259–260° (decomp.) (Johnson and Chernoff, *loc. cit.*, give m. p. 259°, decomp.); mixed m. p. with the dithiohydantoin (XIV) 244° (decomp.).

2 : 4-Dithio-5-phenylhydantoin (XIV) (2 g.) and Raney nickel (6 g.) were suspended in ethanol (50 c.c.), and the mixture refluxed for 10 minutes. After filtration from nickel sulphide and evaporation to dryness, the residue was extracted with ether to yield, on removal of solvent, 5(4)-phenyliminazole (XVII) (0.5 g.) (Found : C, 75.0; H, 5.8. Calc. for $C_8H_8N_2$: C, 75.0; H, 5.6%), which crystallised from benzene in plates, m. p. 133–134° (Pinner, *Ber.*, 1902, 35, 4135, gives m. p. 128–129°). 1' : 5-Bis-(2 : 4-dithio-5-phenylhydantoin) (XV) (2.5 g.) was refluxed in ethanol (50 c.c.) with Raney nickel (6 g.) for 0.5 hour. Filtration and evaporation yielded 5(4)-phenyliminazole (XVII), m. p. 133–134°, extracted from the residue with ether.

5-Phenylhydantoin (1.2 g.) (Lehmann, *Ber.*, 1901, 34, 372) was boiled in tetralin (20 c.c.) with phosphorus pentasulphide (3 g.) for 2 hours. The hot solvent was decanted from the lower oily layer which dissolved in warm 2N-sodium hydroxide (50 c.c.), and yielded 5(4)-phenyliminazole (XVII) (0.6 g.), m. p. 132–133° (mixed m. p. with product from Raney nickel desulphurisation of the dithiohydantoin, 133–134°), on cooling.

5-Amino-2-mercapto-4-phenylthiazole (IV) (20 g.) was boiled with 2N-sodium hydroxide (250 c.c.) until the solution no longer gave an intense red colour with aqueous glyoxal (0.5 hr.). Chloroform

(100 c.c.) and benzyl chloride (25 g.) were then added, and the mixture shaken for 4 hours. The plates, m. p. 108°, which had separated (28 g.) were filtered off and washed with chloroform. This substance was a sodium salt, recrystallisation of which from acetic acid yielded 2 : 4-dithio-5-phenyl-1(or 3)-benzylhydantoin in needles, m. p. 194° (Found : C, 64.2; H, 4.6; N, 9.2. $C_{16}H_{14}N_2S_2$ requires C, 64.2; H, 4.7; N, 9.4%). Light absorption (ethanol) : λ_{\max} 277 m μ , $E_{1\%}^{1\text{cm}}$ = 750. The above sodium salt (16 g.) was dissolved in warm ethanol (50 c.c.), and benzyl chloride (6.5 g.) added. After standing at room temperature for 1 hour the sodium chloride was filtered off, and evaporation of the filtrate to small bulk in a vacuum gave a mass of colourless needles. 2 : 4-Dithio-5-phenyl-1 : 3-dibenzylhydantoin crystallised from chloroform-light petroleum (b. p. 40–60°) in needles, m. p. 114° (Found : C, 69.6; H, 5.2; N, 7.4; S, 16.7. $C_{22}H_{20}N_2S_2$ requires C, 71.1; H, 5.2; N, 7.2; S, 16.5%). Light absorption (chloroform) : λ_{\max} 277 m μ , $E_{1\%}^{1\text{cm}}$ 390. The substance was recovered unchanged after refluxing for 0.5 hour in acetic anhydride. A little of the dibenzyl derivative was dissolved in acetic acid, and the crystalline hydrochloride precipitated by addition of a few drops of ethanolic hydrogen chloride. 2 : 4-Dithio-5-phenyl-1 : 3-dibenzylhydantoin hydrochloride crystallised from acetic acid in colourless needles, m. p. 168–170° (Found : C, 64.6; H, 5.1; N, 6.6; S, 14.7. $C_{22}H_{20}N_2S_2 \cdot HCl$ requires C, 65.0; H, 5.0; N, 6.6; S, 15.1%). It was soluble in ethanol and insoluble in acetone.

1' : 5-Bis-(2 : 4-dithio-5-phenylhydantoin) (XV) (0.5 g.) was refluxed with 2N-sodium hydroxide (10 c.c.) for 1 hour. Acidification yielded 2 : 4-dithio-5-phenylhydantoin (XIV) (0.4 g.), m. p. 267–268° (decomp.); (XIV) was stable in alkali. 2 : 4-Dithio-5-phenylhydantoin (2 g.) was boiled with 50% sulphuric acid (25 c.c.) for 24 hours, the material initially turning orange with simultaneous evolution of sulphur dioxide. The mixture was diluted with water, and the insoluble crystals, m. p. 261° (decomp.), collected. After treatment with 2N-sodium hydroxide and removal of a little insoluble material, m. p. 257–261°, acidification gave orange 1' : 5-bis-(2 : 4-dithio-5-phenylhydantoin) (XV), m. p. 270–271° (decomp.).

A warm saturated solution of the dithiohydantoin (XIV) in ethanol was treated with iodine in ethanol; immediate decolourisation occurred and 1' : 5-bis-(2 : 4-dithio-5-phenylhydantoin) (XV) was precipitated, m. p. 272° (decomp.). Ferric chloride added to an acetic acid solution gave a similar result. Hydrogen peroxide in ethanol gave an insoluble product, m. p. 271–272° (decomp.), which, however, was not identical with 1' : 5-bis-(2 : 4-dithio-5-phenylhydantoin). When an ethanolic solution of 2 : 4-dithio-5-phenylhydantoin was refluxed, the bis-compound (XV) was slowly deposited owing to aerial oxidation.

Reactions with α -Aminopropionitrile.—Acetaldehyde-ammonia (73 g.) was added in portions during 2 hours to ice-cold anhydrous hydrogen cyanide (48 c.c.), and the mixture kept for 2 hours at room temperature and distilled at 12–15 mm. (Delépine, *Bull. Soc. chim.*, 1903, **29**, 1184). Two main fractions were obtained, (A) b. p. 65–75°, and (B), b. p. 115–125°, as well as smaller intermediate fractions. Fraction (A), which is essentially α -aminopropionitrile (2.1 g.), was kept with carbon disulphide (2.3 g.) in ethanol (25 c.c.) for 2 days. 2 : 4-Dithio-5-methylhydantoin (3 g.) separated, m. p. 224° (decomp.), and was crystallised by solution in aqueous ammonia (d 0.880), dilution with 50% ethanol, and precipitation with 2N-hydrochloric acid. The compound was insoluble in common solvents except pyridine, and readily darkened on exposure to light and air. It was soluble in aqueous alkali and the solution gave a red colour with sodium nitroprusside but not with glyoxal. In the presence of acetaldehyde, formation of dithiohydantoin in the above reaction was completely inhibited and the acetaldehyde Schiff's base of the corresponding thiazole (see below) was obtained, though in poor yield.

Fraction (B), diluted with ethanol, was kept overnight with excess of carbon disulphide, and a mass of colourless needles of the acetaldehyde Schiff's base of 5-amino-2-mercapto-4-methylthiazole, m. p. 203° (decomp.), separated (Found : C, 42.1; H, 4.8; N, 16.1; S, 37.2. $C_6H_8N_2S_2$ requires C, 41.9; H, 4.7; N, 16.3; S, 37.2%). The compound was soluble in hot ethanol, ethyl acetate, and acetic acid, and in cold dioxan and pyridine. It readily darkened on exposure to light or on heating in solvents. The Schiff's base was readily soluble in aqueous alkali, and on warming, acetaldehyde was evolved; warm dilute acids also liberated acetaldehyde. When ethanolic hydrogen chloride was added to a solution of the Schiff's base in warm ethyl acetate, 5-amino-2-mercapto-4-methylthiazole hydrochloride, m. p. 197° (decomp.), was rapidly precipitated (Found : C, 26.6; H, 4.1; N, 14.8. $C_6H_8N_2S_2 \cdot Cl$ requires C, 26.3; H, 3.8; N, 15.3%). The compound was insoluble in acetic acid, acetone, and ethanol, soluble in methanol and water, and was best crystallised from methanol and ether. It darkened on exposure to light, and did not yield a free base on treatment with aqueous sodium hydrogen carbonate; treatment of a methanolic or aqueous solution of the above hydrochloride with aqueous glyoxal gave an immediate scarlet precipitate.

α -Aminopropionitrile hydrochloride (5.3 g.) (Dubsy, *Ber.*, 1916, **49**, 1048) was suspended in ethanol (25 c.c.) containing a little phenolphthalein and titrated to neutrality with N-ethanolic sodium ethoxide. After filtration from sodium chloride, the mixture was set aside over-night at 0° with carbon disulphide (4 c.c.). 2 : 4-Dithio-5-methylhydantoin (1.1 g.), m. p. 223° (decomp.), separated, and addition of ethereal hydrogen chloride to the filtrate gave 5-amino-2-mercapto-4-methylthiazole hydrochloride (1.1 g.), m. p. 197° (decomp.).

Reaction with Ethyl Aminocynoacetate.—An ethereal solution of the ester (see Part I, *loc. cit.*) was kept overnight at 0° with excess of carbon disulphide. Extraction and crystallisation of the residue from ethanol yielded colourless barrel-shaped tablets of 5-amino-2-mercapto-4-carbethoxythiazole, m. p. 182–183° (decomp.) (Found : C, 35.7; H, 4.0; N, 13.4. $C_8H_8O_2N_2S_2$ requires C, 35.3; H, 3.9; N, 13.7%). The compound contains a diazotisable group but did not give a colour with glyoxal. The above compound (2 g.) was suspended in ethanol (30 c.c.) with Raney nickel (6 g.) and refluxed for 15 minutes. Filtration of the intensely blue fluorescent solution and evaporation yielded 5-amino-4-carbethoxythiazole, m. p. 163° after crystallisation from ethyl acetate, undepressed by the material described in the preceding paper.

5-Amino-2-mercapto-4-carbethoxythiazole (1.0 g.) was refluxed with methyl iodide (1.0 g.) in ethanol (5 c.c.) for 3 minutes, and the plates (1.5 g.) which separated on cooling recrystallised from methanol and

ether to give 5-amino-2-methylthio-4-carbethoxythiazole hydriodide, m. p. 164–165° (decomp.) (Found: N, 8.1. $C_7H_{11}O_2N_2S_2$ requires N, 8.1%). Treatment with aqueous sodium hydrogen carbonate readily yielded the corresponding base, which crystallised from aqueous ethanol in long needles, m. p. 108° (Found: C, 38.8; H, 5.1; N, 13.1; S, 29.4. $C_7H_{10}O_2N_2S_2$ requires C, 38.5; H, 4.6; N, 12.8; S, 29.4%).

Reaction with Carbon Dioxide.— α -Aminobenzyl cyanide (1 g.) was dissolved in ethanol (30 c.c.), and a slow stream of carbon dioxide passed through the solution overnight. The flocculent precipitate was recrystallised from acetic acid to give α -cyano- α' -carbamyldibenzylurea (XVIII; R = H, R' = Ph), m. p. 224° (decomp.) (Found: C, 66.0; H, 5.3. $C_{17}H_{16}O_2N_4$ requires C, 66.2; H, 5.2%). The compound was only slowly attacked by boiling dilute acids and alkalis.

320. *Syntheses of Some Amino-acids, including Methionine.*

By J. R. CATCH, A. H. COOK, A. R. GRAHAM, and SIR IAN HEILBRON.

Methyl-, ethyl-, and benzyl-thiol readily combined with acraldehyde in presence of organic bases to give β -methyl-, -ethyl-, and -benzyl-thiopropaldehydes, which were satisfactorily converted by the Strecker reaction into methionine, ethionine, and S-benzylhomocysteine respectively. Similar reactions employing benzylthiol with crotonaldehyde or β -methylcrotonaldehyde led to the corresponding α -amino- γ -benzylthio-acids of which the second was debenzylated to α -amino- γ -mercapto- γ -methyl-*n*-valeric acid. In accordance with this formulation, the acid did not behave like a substituted cysteine but gave thiazans (*i.e.*, 6-membered ring compounds) by condensation with carbonyl compounds. Some of the above amino-acids were also obtained by indirect hydrolysis of the corresponding nitriles *via* heterocyclic intermediates.

THIS work was carried out in connection with the synthesis of α -amino- γ -mercapto- γ -methyl-*n*-valeric acid (I). This acid is of interest in view of its relationship to penicillamine (II), a degradation product of the various naturally occurring penicillins, and therefore presents the possibility of obtaining analogues of the natural antibiotics.

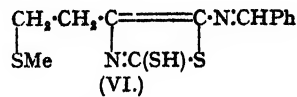

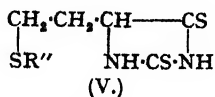

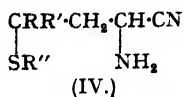

Compounds which might have provided the closest models for the synthesis of (I) were methionine and homocysteine. However the syntheses of these acids which have hitherto been considered most practicable would require, when applied to (I), intermediates of doubtful accessibility. An obvious route to methionine, the Strecker reaction applied to β -methylthiopropaldehyde (III; R, R' = H; R'' = Me), has been explored by Barger and Coyne (*Biochem. J.*, 1928, 22, 1420) and rejected as a useful method because of poor yields. Despite this circumstance it seemed worth while exploring the possibilities of working with the analogue (III; R, R' = Me; R'' = H or other group).

The aldehyde (III; R, R' = H; R'' = Me) has previously been obtained (Barger and Coyne, *loc. cit.*) from β -chloropropaldehyde diethylacetal *via* the β -methylthioacetal, but direct addition of thioacetic acid or thiols to $\alpha\beta$ -unsaturated aldehydes offered an improved route. Kaneko and Mii (*J. Chem. Soc. Japan*, 1938, 59, 1382; *C.A.*, 1939, 33, 2106), and Rothstein (*J.*, 1940, 1560) have described the addition of methyl- and ethyl-thiol respectively to acraldehyde, but the conditions employed by the first-mentioned authors are obscure and the yield recorded for the second addition is poor. It has now been found that thioacetic acid readily adds to acraldehyde, crotonaldehyde, and β -methylcrotonaldehyde to give satisfactory yields of β -acetylthio-propaldehyde, -*n*-butaldehyde, and -isovaleraldehyde (III; R, R' = H; R = H, R' = Me; R, R' = Me respectively, R'' = Ac); these formulations are based on analogy with additions of thiols (see below) where there can be no doubt of the direction of addition. Meanwhile, similar reactions with thiols were found to proceed equally readily, and closer attention was paid to them in view of the greater probability of cleaner transformations at later stages.

Methyl- and ethyl-thiols were found to react quickly with acraldehyde at 0° in presence of a catalytic quantity of a strong base such as triethylamine to give β -methylthio- and β -ethylthio-propaldehyde (III; R, R' = H; R'' = Me, Et, respectively) in good yield. In similar fashion benzylthiol and the appropriate $\alpha\beta$ -unsaturated aldehyde afforded β -benzylthio-propaldehyde, -*n*-butaldehyde, and -isovaleraldehyde (III; R, R' = H; R = H, R' = Me; R, R' = Me respectively, R'' = CH₂Ph). All these aldehydes were characterised as their dinitrophenylhydrazones.

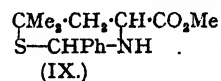

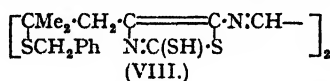

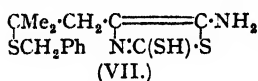

β -Methylthiopropaldehyde was converted by anhydrous hydrogen cyanide followed by ammonia into α -amino- γ -methylthio-*n*-butyronitrile (IV) (R, R' = H, R'' = Me) which was more conveniently isolated as its oxalate than as its hydrochloride. In the same way the homologous nitrile (IV; R, R' = H, R'' = Et) was obtained, also as its oxalate, and the

above-mentioned benzylthioaldehydes were similarly converted into the nitriles (IV; $R'' = \text{CH}_2\text{Ph}$; $R, R' = \text{H}$; $R = \text{H}, R' = \text{Me}$; $R, R' = \text{Me}$), isolated as their *hydrochlorides*.

Facile hydrolysis of certain α -amino-nitriles has been effected (Cook, Heilbron, and Levy, in the press) by first allowing them to react with carbon disulphide and refluxing the resulting 5-amino-2-mercaptothiazoles with dilute mineral acids, and the behaviour of some of the present α -amino-nitriles under these conditions was therefore investigated. α -Amino- γ -methylthio-*n*-butyronitrile and carbon disulphide gave 5- β -methylthioethylthiohydantoin (V) ($R'' = \text{Me}$) directly, though the anticipated 5-amino-2-mercapto-4- β -methylthioethylthiazole could be obtained as its *benzylidene* derivative (VI) by carrying out the condensation in presence of benzaldehyde (Cook, Heilbron, and Levy, *loc. cit.*). The nitrile (IV; $R, R' = \text{H}$; $R'' = \text{Et}$) similarly afforded 5-ethylthioethylthiohydantoin (V; $R'' = \text{Et}$). Hydrolysis of (V; $R'' = \text{Me}$) and of (VI) yielded methionine as was anticipated, but in these instances there was no advantage in proceeding *via* the heterocyclic compounds for methionine could be obtained in satisfactory yield by direct hydrolysis of the appropriate nitrile with boiling hydrochloric acid. It is noteworthy that by the steps outlined above methionine was obtained from acraldehyde in an overall yield of 29%, the process thus appearing much superior to earlier preparations. Ethionine was obtained similarly in equally satisfactory yield.

Two of the above α -aminobenzylthio-nitriles (IV; $R'' = \text{CH}_2\text{Ph}$; $R = \text{H}, R' = \text{H}$ or Me) were hydrolysed similarly without difficulty to give *s*-benzylhomocysteine and α -amino- γ -benzylthio-*n*-valeric acid respectively. The third α -aminobenzylthio-nitrile (IV) ($R'' = \text{CH}_2\text{Ph}$; $R, R' = \text{Me}$) was however converted into the corresponding α -amino-acid only in poor yield by direct hydrolysis. It was fortunate that in this case reaction with carbon disulphide under selected conditions gave not a dithiohydantoin but 5-amino-2-mercapto-4- β -benzylthioisobutylthiazole (VII). Unlike the previous dithiohydantoins, compound (VII) was not only pseudoacidic but was also basic and condensed easily with glyoxal in the characteristic manner of 5-amino-

2-mercaptothiazoles to give the *bisazomethine* derivative (VIII). The thiazole (VII) could be hydrolysed without difficulty and thus satisfactorily afforded α -amino- γ -benzylthio- γ -methyl-*n*-valeric acid. The benzyl group was removed from the latter compound by means of sodium in liquid ammonia to give α -amino- γ -thiol- γ -methyl-*n*-valeric acid (I).

The direction of addition of methyl- and ethyl-thiol to acraldehyde is clear from the eventual emergence of methionine and ethionine. That similar additions of benzylthiol take place in a comparable direction to that postulated above seems certain in that the amino-acid formulated as (I) failed to give the indigo-blue colour with ferric chloride which is characteristic of α -amino- β -thiol-acids such as cysteine and its homologues. The acid (I) still however condensed easily with carbonyl compounds, for example giving with benzaldehyde 4-carbomethoxy-6 : 6-dimethyl-2-phenylthiazan (IX) by simultaneous esterification.

It was at first thought that the amine corresponding to the amino-acid (I) might be more easily accessible and worthy of study. To this end β -benzylthio-*n*-butaldehyde and - β -methyl-*n*-butaldehyde were converted into their oximes which were reduced to γ -benzylthio-*n*-butylamine and - γ -methyl-*n*-butylamine. The preparation of the acid (I) however made the debenzylation of these amines less important and the pursuit of this part of the project was discontinued.

EXPERIMENTAL.

Acraldehyde (5.6 g.; 6.7 c.c.) was cooled in ice, and thioacetic acid (7.6 g., 7.1 c.c.) was added. A brisk reaction took place and the product, after standing overnight, was distilled under reduced pressure. β -Acetylthiopropaldehyde, b. p. 92–93°/14 mm., n_D^{20} 1.4943, was obtained as a colourless liquid (68%) (Found : C, 45.9; H, 6.4; S, 23.0. $\text{C}_5\text{H}_8\text{O}_2\text{S}$ requires C, 45.4; H, 6.1; S, 24.2%). The *dinitrophenylhydrazones* recrystallised from ethanol in yellow needles, m. p. 127.5° (Found : C, 42.5; H, 4.2. $\text{C}_{11}\text{H}_{10}\text{O}_5\text{N}_2\text{S}$ requires C, 42.3; H, 3.9%). Crotonaldehyde (21 g.) and thioacetic acid (22.5 g.) reacted as above. β -Acetylthio-*n*-butaldehyde had b. p. 91–92°/11 mm., n_D^{20} 1.4882 (65%) (Found : C, 49.8; H, 7.2. $\text{C}_8\text{H}_{10}\text{O}_2\text{S}$ requires C, 49.3; H, 6.9%). The *dinitrophenylhydrazones* crystallised from ethanol in yellow hexagonal plates, m. p. 96° (Found : C, 44.4; H, 4.4. $\text{C}_{11}\text{H}_{10}\text{O}_5\text{N}_2\text{S}$ requires C, 44.2; H, 4.3%).

β -Methylcrotonaldehyde (8 g.) and thioacetic acid (8 g.) similarly gave β -acetylthio- β -methyl-n-butanaldehyde, b. p. 110°/20 mm., n_D^{20} 1.4922 (33%). The *dinitrophenylhydrazones* crystallised from ethanol in yellow rhombic plates, m. p. 94° (Found: C, 45.6; H, 4.6. $C_{13}H_{11}O_4N_4S$ requires C, 45.9; H, 4.7%).

Methylthiol, generated from S-methylisothiouraea sulphate (60 g.) and 5N-sodium hydroxide (100 c.c.) (*Org. Synth.*, Coll. Vol. II, 345), was passed in a slow stream of coal gas into acraldehyde (20 g.) containing triethylamine (2 drops) and cooled to 0°. The mixture was distilled and the fraction, b. p. 165–175°, collected (32 g.; 86%). Redistillation gave β -methylthiopropaldehyde, b. p. 166°/750 mm. (Barger and Coyne, *Biochem. J.*, 1928, 22, 1420, give b. p. 60°/12 mm.), n_D^{20} 1.4824 (Found: C, 46.0; H, 7.5; S, 30.3. Calc. for C_4H_8OS : C, 46.1; H, 7.8; S, 30.8%). The *dinitrophenylhydrazones* crystallised from ethanol in yellowish-orange needles, m. p. 122–123° (Found: C, 42.5; H, 4.4. $C_{10}H_{12}O_4N_4S$ requires C, 42.2; H, 4.3%). Ethylthiol (12 g.) was added dropwise with stirring to a mixture of acraldehyde (10 g.) and triethylamine (5 drops) cooled to 0°. Distillation of the product gave β -ethylthiopropaldehyde, b. p. 180–190° (62%) which, on redistillation, had b. p. 185°/760 mm. (Rothstein, *J.*, 1940, 1560, gives b. p. 60°/10 mm.), n_D^{20} 1.4788 (Found: C, 50.4; H, 8.2; S, 27.4. Calc. for $C_5H_{10}OS$: C, 50.8; H, 8.5; S, 27.1%). The *dinitrophenylhydrazones* crystallised from 90% aqueous ethanol, in orange-red laths, m. p. 100° (Found: C, 44.6; H, 4.6; N, 18.4. $C_{11}H_{14}O_4N_4S$ requires C, 44.3; H, 4.7; N, 18.4%).

To acraldehyde (5.6 g.; 6.7 c.c.) cooled in ice, benzylthiol (12.4 g.) was added, followed by a droplet of piperidine. Heat was evolved. After 15 minutes at 0° and 1 hour at room temperature, ether was added and the solution washed with dilute hydrochloric acid and water, dried, evaporated, and distilled. β -Benzylthiopropaldehyde was obtained as a colourless oil, b. p. 158°/12 mm., n_D^{20} 1.5650 (15 g.; 83%) (Found: C, 66.65; H, 6.90; S, 18.0. $C_{10}H_{12}OS$ requires C, 66.65; H, 6.90; S, 17.8%). The *dinitrophenylhydrazones* crystallised from ethanol in yellow needles, m. p. 112.5° (Found: C, 53.5; H, 4.7. $C_{11}H_{14}O_4N_4S$ requires C, 53.3; H, 4.5%). Crotonaldehyde (28 g.; 32.8 c.c.) and benzylthiol (50 c.c.) were mixed at 0°, a droplet of piperidine was added, and the mixture was kept at room temperature for 3 hours and heated on the steam-bath for 1 hour. The product was isolated as above. β -Benzylthio-n-butanaldehyde (68 g.; 87%) had b. p. 156–157°/10 mm., n_D^{20} 1.5523 (Found: C, 68.2; H, 7.4; S, 16.9. $C_{11}H_{14}OS$ requires C, 68.0; H, 7.3; S, 16.5%). The *dinitrophenylhydrazones* crystallised from ethanol in small yellow leaflets, m. p. 69° (Found: C, 54.2; H, 4.9. $C_{17}H_{18}O_4N_4S$ requires C, 54.5; H, 4.8%).

Benzylthiol (7.5 c.c.) containing piperidine (5 drops) was added to freshly prepared β -methylcrotonaldehyde (5 g.) and the mixture heated on the steam-bath for 3 hours. β -Benzylthioisovaleraldehyde was isolated as above (7 g.; 56%), b. p. 109–110°/0.1 mm., 172°/15 mm., n_D^{20} 1.5484 (Found: C, 69.2; H, 7.6; S, 15.9. $C_{12}H_{16}OS$ requires C, 69.2; H, 7.7; S, 15.4%). The *dinitrophenylhydrazones* crystallised from ethanol in needles, m. p. 113° (Found: C, 55.7; H, 5.1. $C_{18}H_{20}O_4N_4S$ requires C, 55.6; H, 5.2%).

A mixture of β -benzylthiopropaldehyde (1.12 g.) and hydrogen cyanide (1 c.c.) at 0° was treated with a droplet of piperidine. After 0.5 hour at room temperature a small excess of ethereal hydrogen chloride was added and the excess of hydrogen cyanide removed under reduced pressure. After addition of 10% alcoholic ammonia (3 c.c.), the solution was sealed, left overnight, heated at 100° for 0.5 hour, concentrated under reduced pressure, taken up in ether, and filtered. Addition of ethereal hydrogen chloride precipitated an oil which readily crystallised (820 mg.; 55%). Recrystallisation from ethanol-ether gave *α*-amino- γ -benzylthio-n-butyronitrile hydrochloride in rosettes of hair-like needles, m. p. 134–135° (Found: C, 54.45; H, 6.4. $C_{11}H_{12}N_2ClS$ requires C, 54.4; H, 6.2%). β -Benzylthio-n-butanaldehyde (10 g.), hydrogen cyanide (10 c.c.), and potassium cyanide (100 mg.) were mixed. A violent reaction ensued and the mixture was then treated as above with 10% alcoholic ammonia (5 c.c.) and left overnight. *α*-Amino- γ -benzylthio-n-valeronitrile hydrochloride crystallised (9 g.; 68%) and after recrystallisation from ethanol-ether formed slender needles, m. p. 159° (decomp.) (Found: C, 55.7; H, 6.7; N, 11.0; S, 12.5. $C_{12}H_{13}N_2ClS$ requires C, 56.1; H, 6.7; N, 10.9; S, 12.5%). β -Benzylthioisovaleraldehyde (2.9 g.) and hydrogen cyanide (1 c.c.) were treated as above. *α*-Amino- γ -benzylthio- γ -methyl-n-valeronitrile hydrochloride recrystallised from ethanol-ether in triangular plates, m. p. 156–157° (1.0 g.; 27%) (Found: C, 57.4; H, 7.3; N, 9.9. $C_{13}H_{15}N_2ClS$ requires C, 57.6; H, 7.1; N, 10.35%).

β -Benzylthio-n-butanaldehyde (15 g.), potassium acetate (15 g.), hydroxylamine hydrochloride (5.5 g.), and ethanol (100 c.c.) were refluxed for 30 minutes, left over-night, and the oxime precipitated by adding water. A portion of the oily oxime (5 g.) in moist ether (150 c.c.) was reduced by refluxing with amalgamated aluminium (4 g.) overnight. The solution was filtered and the alumina washed with further ether. The filtrate was washed, dried, concentrated, and distilled. The fraction, b. p. 85–95°/0.1 mm., was redistilled to give γ -benzylthio-n-butylamine as a colourless oil (2 g.), b. p. 90–92°/0.1 mm., n_D^{20} 1.5545 (Found: C, 67.3; H, 9.0; N, 7.2. $C_{11}H_{17}NS$ requires C, 67.6; H, 8.8; N, 7.2%). The hydrochloride, prepared with ethereal hydrogen chloride, recrystallised from ethanol-ether in rhombic plates, m. p. 123° (Found: C, 57.1; H, 7.9; N, 6.4. $C_{11}H_{16}NClS$ requires C, 57.0; H, 7.9; N, 6.0%).

β -Benzylthio- β -methyl-n-butanaldehyde (5 g.), potassium acetate (5 g.), hydroxylamine hydrochloride (2 g.), and ethanol (40 c.c.) were treated as before and the product reduced with aluminium amalgam (4 g.). The fraction, b. p. 160–165°/15 mm., was redistilled to give γ -benzylthio- γ -methyl-n-butylamine as a colourless oil (25%), b. p. 102–104°/0.1 mm., n_D^{20} 1.5521 (Found: C, 69.0; H, 8.7; N, 6.1. $C_{13}H_{19}NS$ requires C, 68.8; H, 9.2; N, 6.7). The hydrochloride recrystallised from ethanol-ether, m. p. 157° (Found: C, 58.7; H, 8.0; N, 5.8. $C_{13}H_{18}NClS$ requires C, 58.6; H, 8.2; N, 5.7%).

β -Methylthiopropaldehyde (6.3 g.), anhydrous hydrogen cyanide (5 c.c.), and potassium cyanide (100 mg.) were mixed; a vigorous reaction took place. The excess of hydrogen cyanide was removed under reduced pressure and the residue sealed up with 10% ethanolic ammonia (40 c.c.), heated to 80° for two hours, and left overnight. Ethanol and ammonia were removed under reduced pressure, water and chloroform were added, and the basic fraction was isolated in the chloroform. After removal of the solvent, the residue was taken up in ethanol and ethanolic anhydrous oxalic acid was added. A white solid was precipitated (6.9 g.; 65%). Recrystallisation from ethanol gave *α*-amino- γ -methylthio-n-butyronitrile oxalate in colourless laths, m. p. 200° (decomp.) (Found: C, 41.3; N, 6.5; S, 15.3. $C_8H_{10}N_2S_2O_4$ requires C, 41.1; H, 6.3; N, 16.0%). β -Ethylthiopropaldehyde (10 g.), hydrogen cyanide (10 c.c.), and potassium cyanide (ca. 100 mg.) were treated as above. *α*-Amino- γ -ethylthio-

n-butyronitrile oxalate recrystallised from ethanol in colourless laths, m. p. 230° (decomp.) (3.5 g.) (Found: C, 42.2; H, 7.1; N, 14.5. $C_8H_{12}N_2S_2O_6 \cdot \frac{1}{2}H_2O$ requires C, 42.4; H, 7.1; N, 14.1%).

α -Amino- γ -methylthio-*n*-butyronitrile, from the oxalate (2.5 g.), was refluxed with concentrated hydrochloric acid (10 c.c.) for 1½ hours. The solution was evaporated to dryness under reduced pressure, basified with concentrated aqueous ammonia, and re-evaporated. The residue was dissolved in warm water (20 c.c.), charcoaled, and diluted with ethanol (50 c.c.). Methionine crystallised in glistening plates (1.1 g., 52%), and after recrystallisation from water-ethanol had m. p. 276° (decomp.) (Found: C, 40.3; H, 7.5; N, 9.4. Calc. for $C_6H_{11}O_2NS$: C, 40.3; H, 7.4; N, 9.4%). α -Amino- γ -ethylthio-*n*-butyronitrile oxalate (1 g.) was refluxed with concentrated hydrochloric acid (5 c.c.) for 2 hours and evaporated to dryness under reduced pressure. The residue was basified with concentrated aqueous ammonia, re-evaporated, dissolved in the minimum quantity of boiling water, and left to crystallise. Ethionine crystallised (400 mg., 46%), and recrystallised from water-ethanol in colourless plates, m. p. 265° (decomp.) (Found: C, 44.4; H, 8.1; N, 8.9. Calc. for $C_6H_{13}O_2NS$: C, 44.2; H, 8.0; N, 8.6%).

α -Amino- γ -methylthio-*n*-butyronitrile oxalate (1 g.) was converted into the free base and extracted into chloroform. The solution was concentrated and the residue refluxed in 50% ethanolic carbon disulphide (5 c.c.) for 2 hours. Concentration of the solution and addition of ether left a yellow solid (47%). Recrystallisation from acetone-water gave 5- β -methylthioethylthiohydantoin in sheaves of yellow hair-like needles, m. p. 212° (decomp.) (Found: C, 34.3; H, 4.4; N, 13.8; S, 47.8. $C_8H_{16}N_2S_2$ requires C, 34.9; H, 4.9; N, 13.6; S, 46.5%). The compound was soluble in aqueous sodium hydroxide, but the resulting solution failed to give a coloration with aqueous glyoxal. Repetition of the above reaction in the presence of benzaldehyde (0.5 c.c.) gave 5-benzylideneamino-2-mercapto-4- β -methylthioethylthiazole (95 mg.) which recrystallised from ethanol in yellow needles, m. p. 200° (decomp.) (Found: C, 53.2; H, 5.0; N, 9.8. $C_{15}H_{18}N_2S_2$ requires C, 53.0; H, 4.8; N, 9.5%). It gave a red coloration on warming with alkali and glyoxal. α -Amino- γ -ethylthio-*n*-butyronitrile, from the oxalate (1 g.), was refluxed with 50% ethanolic carbon disulphide (5 c.c.) and treated as above. 5- β -Ethylthioethylthiohydantoin (40%) recrystallised from ethanol in fine yellow hairs, m. p. 196–197° (decomp.) (Found: C, 37.2; H, 5.2; N, 12.4. $C_7H_{12}N_2S_2$ requires C, 38.2; H, 5.5; N, 12.7%).

5- β -Methylthioethylthiohydantoin (430 mg.) was refluxed with a 1:1 mixture of acetic and concentrated hydrochloric acids (10 c.c.) for two hours and the solution was concentrated under reduced pressure. The solution was made alkaline with ammonia and again evaporated under reduced pressure, taken up in water (5 c.c.), filtered, and diluted with ethanol (15 c.c.). Methionine separated in glistening plates, m. p. 270° (decomp.) (75 mg., 25%), on standing overnight. A similar hydrolysis of 5-benzylideneamino-2-mercapto-4- β -methylthioethylthiazole (190 mg.) gave methionine in plates, m. p. 271° (decomp.) (25 mg., 25%).

α -Amino- γ -benzylthio-*n*-butyronitrile hydrochloride (860 mg.) and 47% aqueous hydrobromic acid (17.5 c.c.) were heated to 100° for 3½ hours with frequent shaking, and the solution evaporated under reduced pressure. The residue was taken up in water, charcoaled, and neutralised with 2*N*-ammonia. A flocculent precipitate of S-benzylhomocysteine (α -amino- γ -benzylthio-*n*-butyric acid) was obtained (450 mg.; 60%), m. p. 190–191°. The m. p. was undepressed on admixture with authentic material. α -Amino- γ -benzylthio-*n*-valeronitrile hydrochloride (257 mg.) and concentrated hydrochloric acid (3 c.c.) were heated in a sealed tube at 100° for 16 hours. The product was worked up as above. α -Amino- γ -benzylthio-*n*-valeric acid (110 mg.) recrystallised from 50% methanol in small plates, m. p. 215–216° (decomp.) (Found: C, 60.0; H, 7.4; N, 5.5. $C_{12}H_{17}O_2NS$ requires C, 60.2; H, 7.15; N, 5.9%). α -Amino- γ -benzylthio- γ -methyl-*n*-valeronitrile hydrochloride (3.8 g.) was added to aqueous sodium hydrogen carbonate, the free base was extracted into ether, the extract was dried and then concentrated under reduced pressure, and the residual oil was refluxed with 50% ethanol-carbon disulphide (20 c.c.) for 3 hours. After concentration under reduced pressure, the solid was filtered off and washed with a little cold ethanol. Further product was obtained by treating the mother liquors with ether (3.1 g.; 70%). 5-Amino-2-mercapto-4- β -benzylthioisobutylthiazole recrystallised from ethanol-water in pale yellow rhombic plates, m. p. 237° (Found: C, 53.9; H, 5.5; N, 9.2; S, 30.6. $C_{14}H_{19}N_2S_2$ requires C, 54.2; H, 5.8; N, 9.0; S, 31.0%). Addition of 50% aqueous glyoxal to a solution of the thiazole in 2*N*-sodium hydroxide gave a red coloration, and after acidification, the bisazomethine derivative was precipitated; it recrystallised from pyridine-water in fine red hairs, m. p. 238° [Found: C, 56.3; H, 5.6; N, 9.0. ($C_{18}H_{21}N_2S_2$) requires C, 56.1; H, 5.4; N, 8.7%]. The thiazole (5 g.) was refluxed in 50% acetic acid-concentrated hydrochloric acid (40 c.c.) for 2 hours, the solution concentrated under reduced pressure, and the residue taken up in water, filtered, and neutralised with 2*N*-ammonia. α -Amino- γ -benzylthio- γ -methyl-*n*-valeric acid separated as a flocculent buff precipitate which recrystallised from hot water in colourless plates, m. p. 178° (2.4 g.; 59%) (Found: C, 61.2; H, 7.4; N, 5.6. $C_{13}H_{19}O_2NS$ requires C, 61.6; H, 7.6; N, 5.5%). The product gave a strong ninhydrin reaction.

The preceding S-benzyl compound (2.4 g.) in liquid ammonia (40 c.c.) was stirred and reduced with sodium (*ca.* 0.6 g.) added in small pieces until a permanent blue colour was obtained. Ammonium chloride (2 g.) was added and the solution evaporated to dryness and evacuated on a water pump to remove remaining traces of ammonia. Etheral hydrogen chloride was added, the solution was filtered, and the residue thoroughly extracted with ethanol. The extract was concentrated under reduced pressure, the residue extracted with chloroform, and the extract re-concentrated. The residual oil solidified under dry ether (1.4 g.; 73%). Recrystallisation from ethanol-ether gave micro-prisms of α -amino- γ -mercapto- γ -methyl-*n*-valeric acid, m. p. 219° (decomp.) (Found: C, 39.4; H, 6.8; N, 7.3; Cl, 18.4; S, 16.6. $C_6H_{14}O_2NCIS$ requires C, 36.07; H, 7.0; N, 7.0; Cl, 17.8; S, 16.0%). The product gave a strong transient purple colour with alkaline nitroprusside, a weak red-brown ferric chloride colour after addition of aqueous sodium hydrogen carbonate, and a deep red-brown coloration with ninhydrin reagent.

α -Amino- γ -benzylthio- γ -methyl-*n*-valeronitrile (1 g.) was refluxed with 50% acetic acid-concentrated hydrochloric acid (10 c.c.) for 2 hours. The solution was concentrated under reduced pressure, and the residue dissolved in water, filtered, and neutralised with 2*N*-ammonia. The crystalline solid which separated was α -amino- γ -benzylthio- γ -methyl-*n*-valeric acid, m. p. 175° (110 mg. or 12%).

α -Amino- γ -mercapto- γ -methyl- n -valeric acid as its hydrochloride (250 mg.), benzaldehyde (1 c.c.), and methanolic hydrogen chloride (2 c.c.) were heated on the steam-bath for 15 minutes; cooled, and the product was extracted with ether. The residual solid was dissolved in water and the solution neutralised with 2N-ammonia. The oil which separated crystallised on scratching and was recrystallised from aqueous ethanol to give needles of 4-carbomethoxy-2-phenyl-6:6-dimethylthiazan, m. p. 105° (Found: C, 63.4; H, 7.2; N, 5.3. $C_{14}H_{18}O_2NS$ requires C, 63.35; H, 7.2; N, 5.3%).

321. Synthetic Antimalarials. Part XXII. Some Quinolylamino-substituted Pyrimidine Derivatives.

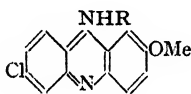

By F. H. S. CURD, W. GRAHAM, (MISS) D. N. RICHARDSON, and F. L. ROSE.

By adapting the methods of preparation utilised for the corresponding anilino-compounds (see earlier papers in this series), series of 2-quinolylamino-4-dialkylaminoalkylamino- and 4-quinolylamino-2-dialkylaminoalkylamino-6-methylpyrimidines have been prepared. Whereas some of the former show activity against *P. gallinaceum* in chicks, the latter are all devoid of activity. Possible explanations for these observations are discussed.

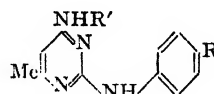

THE preparation of derivatives of 8-chloro-3:4:2':3'-pyridoacridine (I; R = H, R' = dialkylaminoalkyl), possessing considerable antimalarial activity against *P. gallinaceum* in chicks, has recently been reported by Dobson and Kermack (*J.*, 1946, 150). Such compounds may be considered as related to the mepacrine type of antimalarial (II), the 3-methoxy-group of the latter being replaced by the heterocyclic atom of the pyrido-ring. Reference to the structure (III) of the active 2-*p*-substituted anilino-4-dialkylaminoalkylamino-6-methylpyrimidines, described in Parts I and II (*J.*, 1946, 343, 351) showed that a related modification was possible with respect to the substituent R giving rise to quinoline derivatives of type (IV). Further incentive to the preparation of such compounds was provided by the known activity of (III; R = NMe₂, R' = [CH₂]₃·NEt₂) which suggested that activity might be encountered if the dimethylamino-group was replaced by the basic nitrogen atom of a fused heterocyclic ring.

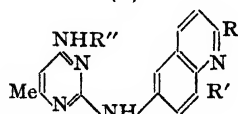

(I.)

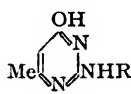

(II.)

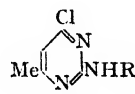

(III.)

(IV.)

(V.)

(VI.)

6-Aminoquinoline was therefore condensed with 4-hydroxy-2-methylthio-6-methylpyrimidine in boiling 2-ethoxyethanol solution to give 2-(6'-quinolylamino)-4-hydroxy-6-methylpyrimidine (V; R = 6-quinolyl), which was converted smoothly into 4-chloro-2-(6'-quinolylamino)-6-methylpyrimidine (VI; R = 6-quinolyl) by treatment with phosphoryl chloride. Condensation of this chloropyrimidine with β -diethylaminoethylamine, γ -diethylaminopropylamine, γ -dimethylaminopropylamine, δ -diethylaminobutylamine and δ -diethylamino- α -methylbutylamine then gave a series of 2-(6'-quinolylamino)-4-dialkylaminoalkylamino-6-methylpyrimidines (IV; R = R' = H, R'' = [CH₂]₃·NEt₂, [CH₂]₃·NEt₂, [CH₂]₃·NMe₂, [CH₂]₄·NEt₂, and CHMe·[CH₂]₃·NEt₂).

By a similar series of reactions using 6-aminoquinaldine in place of 6-aminoquinoline in the initial condensation with 4-hydroxy-2-methylthio-6-methylpyrimidine there were prepared, by way of (V; R = 6-quinaldyl) and (VI; R = 6-quinaldyl), 2-(6'-quinaldylamino)-4- β -diethylaminoethylamino-6-methylpyrimidine (IV; R = Me, R' = H, R'' = [CH₂]₃·NEt₂) and the corresponding 4- γ -diethylaminopropylamino-derivative (IV; R = Me, R' = H, R'' = [CH₂]₃·NEt₂).

All the above compounds showed some antimalarial activity when tested against *P. gallinaceum* in chicks (see table of activities) and it therefore became necessary to investigate the

to prepare the analogous quinoline compound, 2-(5'-bromo-8'-quinolylamino)-4- β -diethylamino-ethylamino-6-methylpyrimidine (VIII; R = H, R' = Br) was unsuccessful. It was found that

the bromine atom in 5-bromo-8-aminoquinoline was somewhat labile, and when the bromo-compound was heated with 4-hydroxy-2-methylthio-6-methylpyrimidine in 2-ethoxy-ethanol at 140°, hydrobromic acid, resulting from its decomposition, brought about hydrolysis of the pyrimidine intermediate to 4-methyluracil.

This investigation has also been concerned with the preparation of 2-dialkylaminoalkylamino-4-(quinolylamino)-6-methylpyrimidines of types (XII) and (XIII) in which the quinolylamino-substituent and the dialkylaminoalkylamino-side chain have been interchanged. 4-Chloro-2- β -diethylaminoethylamino-6-methylpyrimidine (VI; $R = [CH_2]_2 \cdot NEt_2$) (Curd *et al.*, *J.*, 1946, 373) was condensed with 6-aminoquinoline by heating it at 140° to give 4-(6'-quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine (XII; $R = H$) and with 8-aminoquinoline to give 4-(8'-quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine (XIII; $R = H$). Reactions of this type were also effected by boiling in dilute hydrochloric acid. In this way 6-amino-8-methoxyquinoline gave 4-(8'-methoxy-6'-quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine (XII; $R = OMe$) and 5-bromo-8-aminoquinoline afforded 4-(5'-bromo-8'-quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine (XIII; $R = Br$).

These compounds, like those of the previous series, were without antimalarial activity against *P. gallinaceum* in chicks. The contrast between the inactivity of 4-(6'-quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine (XII; $R = H$) and the activity of the isomeric 2-(6'-quinolylamino)-4- β -diethylaminoethylamino-6-methylpyrimidine (IV; $R = R' = H$, $R'' = [CH_2]_2 \cdot NEt_2$), finds an analogy in the corresponding naphthylamino-derivatives. Thus 4-(6'-bromo- β -naphthylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine and related compounds show little or no activity (Part VI, *J.*, 1946, 370), whereas the isomeric 2-(6'-bromo- β -naphthylamino)-4- β -diethylaminoethylamino-6-methylpyrimidine is highly active (Curd *et al.*, *J.*, 1946, 366).

TABLE I.

Antimalarial Activities.

The antimalarial tests were carried out, as in previous investigations of this series, by our colleague Dr. D. G. Davey using *P. gallinaceum* in chicks (cf. Curd, Davey, and Rose, *Ann. Trop. Med. Parasit.*, 1945, 39, 139; Davey, *ibid.*, 1946, 40, 52). The results are expressed in the same way as in previous papers of this series.

(a) 2-(6'-Quinolylamino)- and 2-(6'-Quinaldylamino)-4-dialkylaminoalkylamino-6-methylpyrimidines.

Some of the compounds were also tested for prophylactic action against *P. gallinaceum* in chicks by the method described by Davey (*Ann. Trop. Med. Parasit.*, 1946, 40, 453); 5719, 5720, 5721, and 5398 at 160 mg./kg., 5188 at 240 mg./kg., and 5187 at 80 mg./kg., but all proved to be inactive.

The following points may be noted in connection with the preparation of the requisite quinoline intermediates. 5- and 8-Nitroquinolines, prepared from quinoline in 85% total yield by a method using fuming nitric acid and 20% oleum in place of the 40% oleum used by Meigen (*J. pr. Chem.*, 1908, 77, 472) and 65% oleum by Fieser and Hershberg (*J. Amer. Chem. Soc.*, 1940, 62, 1643), were reduced to the corresponding aminoquinolines with iron dust in dilute acetic acid (Dikshoorn, *Rec. Trav. chim.*, 1929, 48, 153). 6-Nitro-8-methoxyquinoline was prepared by a modified Skraup reaction (cf. E.P. 394,416) using arsenic acid as oxidising agent. When sodium *m*-nitrobenzenesulphonate was used as oxidising agent the only product obtained was a yellow crystalline substance, presumed to be the 4-nitro-2-methoxyanil of β -4'-nitro-2'-methoxyanilinopropaldehyde (Xa), or the cyclic analogue 4-(4'-nitro-2'-methoxyanilino)-6-nitro-8-methoxy-1:2:3:4-tetrahydroquinoline (Xb), probable intermediates in the Skraup synthesis. Reduction of 6-nitro- to 6-amino-8-methoxyquinoline by means of stannous chloride (Fourneau *et al.*, *Ann. Inst. Pasteur*, 1930, 44, 748) was not very satisfactory, and so attempts were made to increase the yield by reduction with iron dust and dilute acetic acid, iron dust and hydrochloric acid, or Raney nickel and hydrogen at 80 atmospheres and at 30 atmospheres. The best yield (50%) was obtained using the last named conditions.

EXPERIMENTAL.

2-(6'-Quinolylamino)-4-hydroxy-6-methylpyrimidine (V; R = 6-quinolyl).—4-Hydroxy-2-methylthio-6-methylpyrimidine (33.2 g.) (Wheeler and Merriam, *Amer. Chem. J.*, 1903, 29, 478), 6-aminoquinoline (72 g.), and 2-ethoxyethanol (75 c.c.) were refluxed for 48 hours with stirring. Methylthiol was evolved. After cooling, the product was filtered off, washed well with hot alcohol, and dried (yield, 35 g.), m. p. 256—258°. The m. p. was unchanged by crystallisation from butanol from which the substance separated as colourless thick prisms (Found: C, 66.6; H, 4.7. $C_{14}H_{12}ON_4$ requires C, 66.7; H, 4.8%).

2-(6'-Quinaldylamino)-4-hydroxy-6-methylpyrimidine (V; R = 6-quinaldyl).—Prepared in an exactly similar manner using 6-aminoquinaldine in place of 6-aminoquinoline, the compound separated from 2-ethoxyethanol in clusters of small colourless needles, m. p. 284° (Found: C, 67.4; H, 5.3; N, 20.4. $C_{15}H_{14}ON_4$ requires C, 67.7; H, 5.3; N, 21.05%).

4-Chloro-2-(6'-quinolylamino)-6-methylpyrimidine (VI; R = 6-quinolyl).—The corresponding hydroxy-compound (28 g.) and phosphoryl chloride (95 c.c.) were refluxed for 4 hours. The excess of phosphoryl chloride was then removed under reduced pressure and the residue treated with a small amount of crushed ice. The solid product was filtered off, dissolved in hot water (150 c.c.) with hydrochloric acid (12.5 c.c.), and the resulting solution treated with decolorising carbon and filtered. The filtrate was cooled and hydrochloric acid (22.5 c.c.) added. The precipitated hydrochloride was filtered off, drained well, and dissolved in warm water (250 c.c.). Gradual addition of ammonia to the cooled solution precipitated the base, which was filtered off, dried in a vacuum, and crystallised from alcohol. It formed colourless prisms, m. p. 183—185° (Found: N, 20.5; Cl, 12.7. $C_{14}H_{11}N_4Cl$ requires N, 20.7; Cl, 13.1%).

4-Chloro-2-(6'-quinaldylamino)-6-methylpyrimidine (VI; R = 6-quinaldyl), prepared in an analogous manner from 2-(6'-quinaldylamino)-4-hydroxy-6-methylpyrimidine (33.25 g.) and phosphoryl chloride (85 c.c.), crystallised from 2-ethoxyethanol in colourless prisms, m. p. 235° (Found: N, 19.9; Cl, 12.5. $C_{15}H_{13}N_4Cl$ requires N, 19.85; Cl, 12.5%).

5- and 8-Nitroquinoline. —The method employed was essentially that of Fieser and Hershberg (*loc. cit.*). Quinoline sulphate, from quinoline (77.5 g.) and concentrated sulphuric acid (35 c.c.), dissolved in 20% oleum (210 g.), was nitrated with nitric acid (d 1.5; 105 g.) giving 5-nitroquinoline (42 g.) and 8-nitroquinoline (45 g.).

6-Nitro-8-methoxyquinoline. —A mixture of 2-amino-5-nitroanisole (100 g.), sulphuric acid (1000 g. of 70%), glycerol (200 g.), and arsenic acid (333 g. of 80%) was heated to boiling during $\frac{1}{2}$ hour and then refluxed for 4 hours with stirring. The temperature of the boiling mixture dropped from 138° to 133° during the course of the reaction. After cooling, the reaction mixture was drowned into water (3 l.), and the solution stirred with decolorising carbon and filtered. Addition of sodium hydroxide solution to the filtrate precipitated 6-nitro-8-methoxyquinoline which was filtered off, washed with water, and crystallised from alcohol, m. p. 149—150° (yield, 82.5 g.). By recrystallisation from acetone the m. p. was raised to 152—153°. Fourneau *et al.* (*loc. cit.*) give m. p. 149°. In an experiment using sodium *m*-nitrobenzenesulphonate as oxidising agent the only material isolated was a substance crystallising from alcohol in yellow needles, m. p. 126—127°. This was presumed to be (Xa) or (Xb) (Found: C, 54.5; H, 4.2; N, 15.0. $C_{17}H_{13}O_2N_4$ requires C, 54.5; H, 4.8; N, 15.0%).

6-Amino-8-methoxyquinoline. —6-Nitro-8-methoxyquinoline (12 g.) dissolved in alcohol (600 c.c.) was hydrogenated in presence of Raney nickel (8 c.c. of sludge) in the cold at 30 atmospheres. After removal of the catalyst and on slight concentration of the alcohol solution a yellow solid separated which crystallised from alcohol-chloroform in yellow needles, m. p. ca. 350° (Found: C, 68.7; H, 4.3; N, 16.5%). Evaporation of the alcohol solution to dryness gave a dark red gummy solid from which, after several crystallisations from ethyl acetate, there was obtained 6-amino-8-methoxyquinoline (yield, 4.6 g.) as yellow laminae, m. p. 167—169°. Fourneau *et al.* (*loc. cit.*) give m. p. 168°.

2-(8'-Quinolylamino)-4-hydroxy-6-methylpyrimidine (V; R = 8-quinolyl). —8-Aminoquinoline (34 g.), 4-hydroxy-2-methylthio-6-methylpyrimidine (34 g.), and 2-ethoxyethanol (40 c.c.) were heated together in an oil-bath at 135—145° for 70 hours. The mixture was then extracted several times with boiling alcohol leaving undissolved 2-(8'-quinolylamino)-4-hydroxy-6-methylpyrimidine (yield, 32.8 g.), m. p. 263—265°, unchanged after recrystallisation from 2-ethoxyethanol from which it separated in colourless prisms (Found: C, 66.5; H, 4.8. $C_{14}H_{12}ON_4$ requires C, 66.7; H, 4.8%).

2-(5'-Quinolylamino)-4-hydroxy-6-methylpyrimidine (V; R = 5-quinolyl).—Prepared in the same way from 5-aminoquinoline (10 g.) and 4-hydroxy-2-methylthio-6-methylpyrimidine (10 g.) in 2-ethoxyethanol (11.4 c.c.), this substance formed a fine white powder (yield, 8.1 g.), m. p. 286—290°, which could not be crystallised.

2-(6'-Methoxy-8'-quinolylamino)-4-hydroxy-6-methylpyrimidine (V; R = 6-methoxy-8-quinolyl), similarly obtained from 8-amino-6-methoxyquinoline (19 g.) and 4-hydroxy-2-methylthio-6-methylpyrimidine (15 g.) in 2-ethoxyethanol (25 c.c.), on crystallisation from 2-ethoxyethanol formed colourless needles (yield, 12.6 g.), m. p. 245—246° (Found: C, 64.2, 64.2; H, 4.5, 4.7. $C_{15}H_{14}O_4N_4$ requires C, 63.85; H, 5.0%).

2-(8'-Methoxy-6'-quinolylamino)-4-hydroxy-6-methylpyrimidine (V; R = 8-methoxy-6-quinolyl) was obtained in the same manner from 6-amino-8-methoxyquinoline (7.9 g.) and 4-hydroxy-2-methylthio-6-methylpyrimidine (6.8 g.) by reaction in 2-ethoxyethanol (9 c.c.). It formed a tan-coloured microcrystalline powder (yield, 5 g.), m. p. 231—235°, from alcohol (Found: C, 62.7; H, 4.7; N, 18.2. $C_{15}H_{14}O_4N_4$, 0.5 C_6H_5 ·OH requires C, 62.95; H, 5.6; N, 18.35%).

4-Chloro-2-(8'-quinolylamino)-6-methylpyrimidine (VI; R = 8-quinolyl).—2-(8'-Quinolylamino)-4-hydroxy-6-methylpyrimidine (5 g.) and freshly distilled phosphoryl chloride (25 c.c.) were heated by means of an oil-bath for 4 hours at 125°. Excess of phosphoryl chloride was removed under diminished pressure and the residue treated with ice and dissolved in hydrochloric acid. The acid solution was filtered, carefully neutralised with ammonia, and the product filtered off, washed with water, and dried in a vacuum. It was then extracted thrice with boiling alcohol (200 c.c.) and filtered from insoluble material (1.5 g.). Concentration of the alcohol solution gave the chloropyrimidine which after recrystallisation from alcohol formed colourless prisms (yield, 3.4 g.), m. p. 146—148° (Found: C, 62.2; H, 4.3. $C_{14}H_{11}N_4Cl$ requires C, 62.1; H, 4.1%).

4-Chloro-2-(5'-quinolylamino)-6-methylpyrimidine (VI; R = 5-quinolyl).—The corresponding hydroxypyrimidine (11.5 g.) and freshly distilled phosphoryl chloride (45 c.c.) were heated at 120° in an oil-bath for 4 hours. After removal of the excess of phosphoryl chloride under reduced pressure at 100° the residue was treated with ice and dissolved in hydrochloric acid. After filtration, the solution was rendered alkaline with ammonia and the precipitated product filtered off, washed with water and dried in a vacuum. It crystallised from alcohol as colourless prisms (yield, 9.6 g.), m. p. 198—200° (Found: C, 62.5; H, 4.2. $C_{14}H_{11}N_4Cl$ requires C, 62.1; H, 4.1%).

4-Chloro-2-(6'-methoxy-8'-quinolylamino)-6-methylpyrimidine (VI; R = 6-methoxy-8-quinolyl), similarly obtained from 2-(6'-methoxy-8'-quinolylamino)-4-hydroxy-6-methylpyrimidine (9.7 g.) and phosphoryl chloride (39 c.c.), formed pale yellow prisms from alcohol (yield, 8.7 g.), m. p. 139—141° (Found: C, 59.7; H, 4.2. $C_{15}H_{13}ON_4Cl$ requires C, 59.9; H, 4.3%).

4-Chloro-2-(8'-methoxy-6'-quinolylamino)-6-methylpyrimidine (VI; R = 8-methoxy-6-quinolyl), prepared in the same way from the appropriate hydroxypyrimidine (5.2 g.) and phosphoryl chloride (21 c.c.), crystallised from benzene as pale yellow prismatic needles (yield, 5 g.), m. p. 213—215° (Found: C, 59.6; H, 4.1; N, 18.7. $C_{15}H_{13}ON_4Cl$ requires C, 59.9; H, 4.3; N, 18.6%).

Preparation of 2-Quinolylamino-4-dialkylaminoalkylamino-6-methylpyrimidines.—The 4-chloro-2-quinolylamino-6-methylpyrimidine (0.25 g.-mol.) and dialkylaminoalkylamine (0.25 × 1.15—2 g.-mol.) were heated at 125—135° (oil-bath) for 8 hours with stirring. After cooling, the resulting melt was dissolved in warm dilute hydrochloric acid, and the cooled solution basified with sodium hydroxide and extracted with chloroform. The chloroform extract was washed with water and shaken out several times with 5% acetic acid. The combined acid extracts were made alkaline with sodium hydroxide and the liberated base was taken into chloroform. After drying (K_2CO_3) and evaporation of the chloroform an oily base remained. This usually solidified on standing, or on trituration with warm light petroleum (b. p. 60—80°) and was then crystallised from light petroleum (b. p. 100—120°). Where the base could not be crystallised, it was converted into the dihydrochloride by dissolving it in 2N-hydrochloric acid and evaporation under reduced pressure at as low temperature as possible. The residue was dried and freed from adhering acid by repeated evaporation to dryness with alcohol-benzene and then purified by crystallisation. Table II details and gives a description of the compounds prepared.

5-Bromo-8-aminoquinoline.—8-Aminoquinoline was converted into its acetyl derivative and brominated in acetic acid. Contrary to the report of Claus and Setzer (*J. pr. Chem.*, 1896, 53, 404) it was found that the hydrobromide of 5-bromo-8-acetamidoquinoline was dissociated in water. The acetyl derivative was hydrolysed to 5-bromo-8-aminoquinoline, the hydrochloride of which was likewise dissociated in water. After two crystallisations from alcohol, 5-bromo-8-aminoquinoline formed fine yellow needles, m. p. 109—110° (Found: C, 48.4; H, 3.5. Calc. for $C_9H_7N_2Br$: C, 48.4; H, 3.15%). Claus and Setzer (*loc. cit.*) give m. p. 104°.

Attempted Condensation of 5-Bromo-8-aminoquinoline and 4-Hydroxy-2-methylthio-6-methylpyrimidine.—The pyrimidine (9.6 g.), 5-bromo-8-aminoquinoline (15 g.), and 2-ethoxyethanol (11 c.c.) were heated in an oil-bath at 135—145° for 72 hours. From the dark red mixture the only products isolated were: (a) 4-methyluracil (5 g.), m. p. 312° (efferv.), identified by conversion into 5-bromo-4-methyluracil, m. p. 230° (Behrend, *Annalen*, 1885, 229, 8), and (b) a water-soluble dark red gum (13 g.) which gave a positive test for ionised bromine. Ionised bromine was detected after 5-bromo-8-aminoquinoline had been heated with 2-ethoxyethanol at 140° for 8 hours, but the bromine in the acetyl derivative showed no such lability when heated with β -diethylaminoethylamine at this temperature.

4-(8'-Quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine (XIII; R = H).—4-Chloro-2- β -diethylaminoethylamino-6-methylpyrimidine (7.2 g.) (Curd *et al.*, *J.*, 1946, 373) and 8-aminoquinoline (5.4 g. 1.25 mol.) were heated in an oil-bath for 8 hours at 140°. The mixture was dissolved in dilute hydrochloric acid, the solution basified with sodium hydroxide, and extracted with chloroform. The chloroform extract was washed with water and then extracted several times with 5% acetic acid. The total acid extract was made alkaline with sodium hydroxide and the precipitated oil extracted with chloroform. The extract, after being washed and dried, was evaporated to dryness, giving the base as a red oil (7 g.) which could not be crystallised. This was dissolved in dilute hydrochloric acid and the solution evaporated to dryness under reduced pressure followed by repeated evaporation with alcohol—

(a) Colourless laminae.

(b) Purified by preliminary vacuum distillation before crystallisation.

(c) Crystallised first from dilute alcohol.

(d) Colourless prisms.

(e) Crystallised from alcohol-ether; yellow needles.

(f) Crystallised from ether-alcohol.

(g) Crystallised from alcohol; colourless fine needles.

(h) Crystallised from alcohol-ether; slightly hygroscopic fine yellow needles, m. p. 202° (efferv.) solidifying and remelting at 260–262°. After drying for 2 hours in a vacuum at 100° it was deeper yellow in colour and had only one m. p. 260° (Found: N, 17.0; Cl, 14.2. C₂₁H₂₆ON₆·2HCl·2.5H₂O requires N, 16.9; Cl, 14.3%).

benzene. The remaining *dihydrochloride* crystallised from alcohol as colourless needles, m. p. 249–251° (Found: C, 54.0, 54.2; H, 6.9, 6.9; N, 19.5, 19.4. $C_{20}H_{22}N_4 \cdot 2HCl \cdot H_2O$ requires C, 54.4; H, 6.8; N, 19.1%).

4-(6'-*Quinolylamino*)-2- β -diethylaminoethylamino-6-methylpyrimidine (XII; R = H), obtained in a similar manner from 4-chloro-2- β -diethylaminoethylamino-6-methylpyrimidine and 6-aminoquinoline, crystallised from benzene-cyclohexane in pale tan-coloured prisms, m. p. 160° (Found: C, 68.8, 68.7; H, 7.3, 7.5; N, 23.8. $C_{20}H_{28}N_6$ requires C, 68.6; H, 7.4; N, 24.0%). The corresponding *trihydrochloride* crystallised from alcohol, forming yellow needles, m. p. 258–261° (Found: C, 47.2; H, 6.8; N, 16.6. $C_{20}H_{28}N_6 \cdot 3HCl \cdot 2.5H_2O$ requires C, 47.6; H, 6.7; N, 16.65%).

4-(8'-*Methoxy-6'-quinolylamino*)-2- β -diethylaminoethylamino-6-methylpyrimidine (XII; R = OMe).—4-Chloro-2- β -diethylaminoethylamino-6-methylpyrimidine (2.8 g., 1 mol.), 6-amino-8-methoxyquinoline (2 g., 1 mol.), concentrated hydrochloric acid (1.27 c.c., 1.1 mol.), and water (12.7 c.c.) were refluxed for 2 hours. The clear solution, when cold, was made alkaline with sodium hydroxide and worked up as described above for this type of compound, giving 4-(8'-methoxy-6'-quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine (yield, 3.7 g.) which formed pale yellow needles from aqueous methanol, m. p. 201–203° (Found: C, 66.3; H, 7.2; N, 22.2. $C_{21}H_{28}ON_6$ requires C, 66.3; H, 7.3; N, 22.1%). The *trihydrochloride*, prepared in the usual manner, crystallised from alcohol in slightly yellow hygroscopic needles, m. p. 222–224° (Found: C, 47.4; H, 6.7. $C_{21}H_{28}ON_6 \cdot 3HCl \cdot 2.5H_2O$ requires C, 47.15; H, 6.7%).

4-(5'-*Bromo-8'-quinolylamino*)-2- β -diethylaminoethylamino-6-methylpyrimidine (XIII; R = Br).—4-Chloro-2- β -diethylaminoethylamino-6-methylpyrimidine (2.9 g.), 5-bromo-8-aminoquinoline (2.67 g.), 10N-hydrochloric acid (1.32 c.c.), and water (13.2 c.c.) were boiled. Initially the mixed solids melted, and as the oil dissolved a solid began to separate. The mixture was refluxed for 2 hours and then left overnight. The 4-(5'-bromo-8'-quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine *dihydrochloride* which separated was collected, dried, and crystallised from alcohol-ethyl acetate forming colourless needles (yield, 4.6 g.), m. p. 268–270° (Found: C, 47.6; H, 5.3; N, 16.5; Cl, 13.0. $C_{20}H_{25}N_4Br \cdot 2HCl$ requires C, 47.8; H, 5.4; N, 16.6; Cl, 14.1%). The free base was obtained by working up the hydrochloric acid mother liquor in the usual manner and also by treatment of the *dihydrochloride* with sodium hydroxide. It crystallised from light petroleum (b. p. 80–100°) as pale yellow rhombs, m. p. 133–134° (Found: C, 55.6; H, 5.7. $C_{20}H_{25}N_4Br$ requires C, 55.9; H, 5.8%).

This research was carried out under a wartime collaborative agreement between the Medical Research Council and Imperial Chemical Industries Ltd. The authors desire to express their thanks to Professor J. W. Cook, F.R.S., and Dr. T. S. Stevens for their interest in the work. One of us (W. G.) gratefully acknowledges the receipt of a grant from the Medical Research Council.

322. Reactions of Benzthiazole Derivatives. Part V. Observations on the Formation of 2-Acetonylbenzthiazole.*

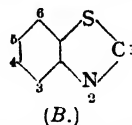

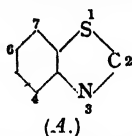

By M. A. THOROLD ROGERS and W. A. SEXTON.

2:2'-Diaminodiphenyl disulphide condenses with ethyl acetoacetate to give 3-keto-2-acetyl-2:3-dihydrobenzthiazine (IV) and 2-acetonylbenzthiazole (V) (with its derived 2-methylbenzthiazole) in approximately equimolecular proportion. Zinc and acetic acid convert (IV) into (V) and sodium hydroxide hydrolyses it to 3-keto-2:3-dihydrobenzthiazine (VI). A similar series is derived from ethyl benzoylacetate. Mechanisms are suggested.

THE formation of 2-acetonylbenzimidazole by condensation of *o*-phenylenediamine with ethyl acetoacetate or by reduction of acetoacet-*o*-nitroanilide has been demonstrated by one of us (Sexton, *J.*, 1942, 303) and its ability to couple with diazonium salts prompted us to investigate the analogous benzthiazole derivative (V).

2:2'-Dinitrodiphenyl disulphide was reduced by iron in alcohol to the diamine, this method giving, in contrast to those hitherto recorded, satisfactory yields of pure material with little trouble. Condensation with ethyl acetoacetate in chlorobenzene gave three products, 2-acetonylbenzthiazole (V) (26.7%), 2-methylbenzthiazole (VII) (21.6%), and 3-keto-2-acetyl-

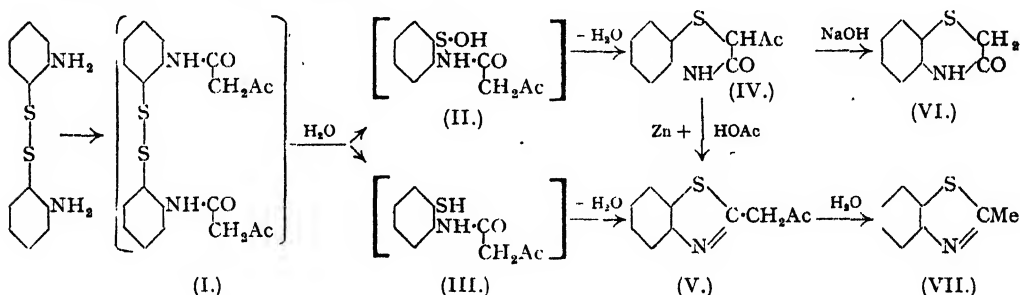

* The numbering of the benzthiazole system (A) here follows what is now the usual practice. In

earlier papers of this series (*J.*, 1939, 470, 473; 1942, 304; 1944, 11) the Richter numbering (B) was used.—EDITOR.

2 : 3-dihydrobenzthiazine (IV) (43%), together with water. The structure of the new compounds was established as follows.

The substance (IV), which crystallised from the chlorobenzene on cooling, and which *a priori* might be expected to be the bis-*N*-acetoacetyl derivative (I) of diaminodiphenyl disulphide, was shown to have a molecular weight of half that required for this structure. Since the possibility of dissociation of (IV) during the molecular-weight determination could not be excluded, and since analysis fails to differentiate between the thiazine and the disulphide structures, (IV) and (I), respectively, a chemical method was sought and found in the action of *N*-sodium hydroxide; for on dissolving in this reagent and being warmed, the whole material was rapidly converted into 3-keto-2 : 3-dihydrobenzthiazine (VI) and acetic acid, the latter being determined by titration. This is easily explained on the basis of the thiazine formula (IV) as hydrolysis, whereas the disulphide structure could give only half the amount of each of these (unless atmospheric oxygen was absorbed, and this was excluded by showing that the reaction is not affected by the absence of air, or by the presence of reducing agents); for the hydrolytic fission of disulphides leads to the formation of equimolecular quantities of thiols and sulphenic acids (see Gilman, "Organic Chemistry", 1942, 2nd Ed., Vol. II, p. 863) and only the sulphenic acid moiety is able to give 3-keto-2 : 3-dihydrobenzthiazine and acetic acid. Other properties of the substance (carbonyl activity, coupling of freshly prepared alkaline solutions with diazonium salts) are as readily understood on the basis of the formula (IV) as on the basis of the disulphide structure (I).

The structure of the other new product of the condensation, (V), presented little difficulty. It was soluble in both acids and alkalis, and the alkaline solution coupled with diazonium solutions; it showed carbonyl activity (2 : 4-dinitrophenylhydrazone) and gave an isonitroso-derivative; and its alkaline solution decomposed rapidly on heating to give 2-methylbenzthiazole. Finally, it was made in good yield from (IV) by reduction with zinc dust and acetic acid, which might be expected if (IV) is considered as a cyclic derivative of acetoacetanilide; the thiol (III) is a probable intermediate.

It is not difficult to postulate a reasonable mechanism for the formation of the three products of the acetoacetic ester condensation. It may be supposed that the bisacetoacetyl derivative (I) of the diamine is the first product, and that this is hydrolysed by traces of water, which may be present initially in the reagents, or may be formed by a Schiff's base type of side reaction. Such a neutral hydrolysis of the disulphide link is not usually considered to take place, but Schöberl and Eck (*Annalen*, 1936, 522, 97) have shown that it is probable that the reaction $-S-S- \rightleftharpoons -SH + -S\cdot OH$ is reversible, with equilibrium much on the side of the disulphide; provided that irreversibility is ensured, in their case by loss of hydrogen sulphide, the hydrolysis can go to completion. We picture the thiol (III) as being removed as soon as it is formed by ring closure to (V), while the sulphenic acid (II) is likewise converted into (IV). The water which is formed in each of these processes is available for further hydrolysis of the disulphide link, and the reaction becomes autocatalytic. Some of the thiazole (V) is hydrolysed during the reaction or during the subsequent steam distillation to methylbenzthiazole, so the combined yields of this and of (V) approach the theoretical of 50%, as does that of (IV).

Similar results were obtained in a brief investigation of the analogous series from ethyl benzoylacetate; 3-keto-2-benzoyl-2 : 3-dihydrobenzthiazine and 2-phenacylbenzthiazole were made in this way.

EXPERIMENTAL.

2 : 2'-Diaminodiphenyl Disulphide.—2 : 2'-Dinitrodiphenyl disulphide (100 g.; the sulphide made as described in *Org. Synth.*, Coll. Vol. I, p. 215, is satisfactory, provided that all inorganic sulphur be

removed by thorough washing with water) was added to a mixture of boiling alcohol (95%; 2 l.) and iron filings (200 g.), to which had been added concentrated hydrochloric acid (10 c.c.) 30 mins. previously. The mixture was heated under reflux for 16 hours in a water-bath in an apparatus fitted with efficient mechanical stirring, and was then filtered hot through a kieselguhr bed and concentrated to 600 c.c. On cooling, the diamine (60 g.; 76%) separated as yellow plates, m. p. 90–92°. One recrystallisation from alcohol (charcoal) gave material of better colour, m. p. 93–93.5°.

3-Keto-2-acetyl-2:3-dihydrobenzthiazine (IV).—The foregoing diamine (12.4 g.), dissolved in warm chlorobenzene (50 c.c.), was added during $\frac{1}{2}$ hr. to a boiling solution of ethyl acetoacetate (14.5 c.c.) in chlorobenzene (75 c.c.). The clear yellow liquid was distilled until wet chlorobenzene (80 c.c.) had been collected. To the residue was added further chlorobenzene (50 c.c.), and the same amount was distilled over. The process was repeated, no more water then appearing in the distillate. The residue was kept overnight, and the pale yellow prisms were collected and washed with light petroleum (b. p. 40–80°) (8.9 g., 43%); recrystallisation (charcoal) from alcohol or toluene gave large, colourless prisms, m. p. 164–164.5° (Found: C, 57.9; H, 4.35; N, 6.75; S, 16.1; M, Rast, 189. $C_{10}H_9O_2NS$ requires C, 57.95; H, 4.35; N, 6.75; S, 15.5%; M, 207). 2:4-Dinitrophenylhydrazones, mustard-yellow micro-needles from toluene, m. p. 242–243° (decomp.) (Found: C, 49.9; H, 3.8. $C_{18}H_{13}O_6N_5S$ requires C, 49.6; H, 3.4%).

2-Acetonylbenzthiazole (V).—(a) *From the ethyl acetoacetate condensation.* The filtrates from the foregoing experiment were subjected to steam distillation; after the chlorobenzene had distilled, the subsequent cloudy distillate had a smell like that of pyridine; about 600 c.c. of this were collected. The yellow oil remaining from the steam-distillation solidified on standing. After one crystallisation from alcohol it gave yellow plates (1.55 g.), m. p. 113–115°. Recrystallisation from alcohol gave colourless plates, m. p. 122° (Found: N, 7.55. $C_{10}H_9ONS$ requires N, 7.35%). The distillate was acidified (hydrochloric acid), whereupon the oily material passed into solution, leaving a little solid which was removed by filtration and identified as 2-acetonylbenzthiazole (0.2 g.; total yield 26.7%). The filtrate was basified to Clayton-yellow with sodium hydroxide, and extracted with ether, and the ether removed by distillation, leaving 2-methylbenzthiazole (1.8 g.; 21.6%), identified as its picrate, m. p. 153–155° (lit. m. p. 152–153°).

(b) *From 3-keto-2-acetyl-2:3-dihydrobenzthiazine (IV).* To the thiazine (5.2 g.) in boiling acetic acid (150 c.c.) was added zinc dust (8 g.) during 10 mins. After refluxing for a further $\frac{1}{2}$ hour, the solution was filtered and cooled, and water was added, precipitating 2-acetonylbenzthiazole (II) as colourless plates (4.2 g., 87.5%), m. p. 122°.

It decolourised bromine in carbon tetrachloride solution; its solutions in cold 2N-sodium hydroxide gave yellow azo-compounds with diazonium solutions; on boiling the alkaline solution, an oil, with a pyridine-like smell, separated after a few minutes, and was extracted with ether, dried over sodium hydroxide, and the ether removed. Addition of alcoholic picric acid to an alcoholic solution of the residue gave the picrate of 2-methylbenzthiazole, m. p. 153–155°. 2-Acetonylbenzthiazole was soluble in hot 2N-hydrochloric acid; on cooling, the hydrochloride separated as colourless needles, m. p. 200° (from 2N-hydrochloric acid or from alcohol). Treatment of a suspension of the hydrochloride in dilute hydrochloric acid with sodium nitrite solution until a permanent starch-iodine reaction was obtained gave pale yellow isonitroso-2-acetonylbenzthiazole, long yellow needles, m. p. 152–152.5° (from alcohol) (Found: C, 54.7; H, 3.6. $C_{10}H_8O_2N_2S$ requires C, 54.55; H, 3.6%).

Action of Alkali on 3-Keto-2-acetyl-2:3-dihydrobenzthiazine (IV).—The thiazine (2.08 g.) was dissolved in boiling N-sodium hydroxide (20 c.c.). After about 3 mins. there separated long needles of 3-keto-2:3-dihydrobenzthiazine (VI); after a further $\frac{1}{2}$ hour at 100°, the suspension was cooled and N-hydrochloric acid (30 c.c.) was added; the solution was filtered through a weighed IG3 sintered-glass Gooch funnel. The ketodihydrothiazine (VI) was washed with water, dried at 100°, and weighed; 1.66 g. (100%); m. p. 179° (not depressed by mixture with an authentic specimen) (Found: N, 8.4; S, 19.4. Calc. for C_8H_7ONS : N, 8.5; S, 19.4%). The yield was not lowered by conducting the reaction in an atmosphere of nitrogen or by the presence of sodium sulphide in the alkaline solution.

A further portion of the thiazine (2.08 g.) was treated with 0.975N-sodium hydroxide (20 c.c.) in the same way; the cooled alkaline suspension was filtered, and the residue washed well with water. Titration of the filtrate, using phenolphthalein, with hydrochloric acid (10 c.c. of 0.929N) shows, by difference, a weak acid content of 1.02 mols. per mol. of thiazine. Similar results were obtained when the hydrolysis was conducted in an atmosphere of nitrogen.

(IV) (2.0 g.) was recovered unchanged (1.5 g.) when its solution in alcohol (20 c.c.) was heated under reflux with 2N-hydrochloric acid (5 c.c.) for 6 hours.

3-Keto-2-benzoyl-2:3-dihydrobenzthiazine.—This was made from ethyl benzoylacetate (42.4 g.) and diaminodiphenyl disulphide (24.8 g.) in chlorobenzene (250 c.c.) as described for (IV); it formed large lemon-yellow prisms, m. p. 188° (Found: C, 66.55; H, 4.0; N, 5.05; M, Rast, 242. $C_{15}H_{11}O_2NS$ requires C, 66.9; H, 4.1; N, 5.2%; M, 269). It formed yellow solutions in hot N-sodium hydroxide which faded on boiling with quantitative formation of the thiazine (VI); acidification of the filtrate gave benzoic acid (m. p. and mixed m. p.). 2-Phenacylbenzthiazole, made by zinc dust reduction of the foregoing compound in acetic acid, formed needles from benzene, m. p. 150° (Found: N, 5.6. $C_{13}H_{11}ONS$ requires N, 5.55%).

323. The Polysaccharides of Carragheen. Part II. The *Gigartina stellata* Polysaccharide.

By ERIC T. DEWAR and E. G. V. PERCIVAL.

The water-soluble polysaccharide of *Gigartina stellata* is shown to resemble the *Chondrus crispus* polysaccharides. Crystalline 2:6-dimethyl β -D-galactose has been isolated by the hydrolysis of the methylated polysaccharide.

ALTHOUGH some authorities ("British Pharmaceutical Codex", London, 1934, p. 320; "Thorpe's Dictionary of Applied Chemistry", Longmans, 4th. Edn. 1937, p. 199) appear to reserve the term carragheen for the red alga *Chondrus crispus*, and it was used in this sense in Part I (J., 1943, 51), others, for example Tseng (*Science*, 1945, 101, 2633) and Newton (*Endeavour*, 1945, IV, 14, 69) also include *Gigartina stellata*, Batt. in this description on account of the close morphological resemblances between the two algae. It is not surprising therefore that the polysaccharides extracted by hot water from these two red seaweeds prove, as the present investigation shows, to be of the same type.

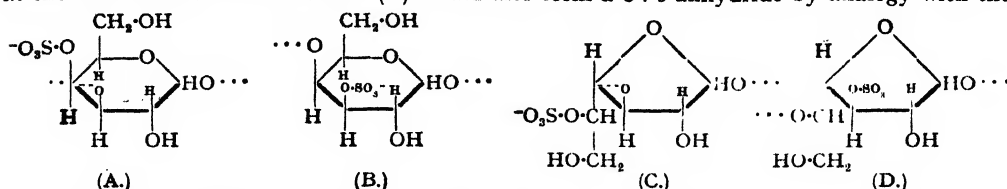

The polysaccharide obtained by the extraction of *Gigartina stellata* with hot water mainly as the calcium salt, but containing in addition magnesium, sodium, and potassium, gave D-galactose (40%) on hydrolysis, and had $[\alpha]_D^{25} + 51^\circ$ in water (SO_4 , 23.9%); the hot extract from *Chondrus crispus* had $[\alpha]_D^{25} + 63^\circ$ (SO_4 , 23.8; galactose 36.9%) (J., 1943, 51). In its stability to sodium hydroxide (N) at 100° the polysaccharide also resembled the *Chondrus* extracts, three days being necessary to remove 62% of the sulphate residues. The free acid polysaccharide was isolated ($[\alpha]_D^{25} + 43^\circ$; SO_4 , 25.9%; neutralisation equivalent, 371) and potentiometric titration showed it to be a typically strong acid. Acetylation was accomplished by a modification of the method of Pacsu and Mullen (*J. Amer. Chem. Soc.*, 1941, 63, 1487), deacetylation and methylation of the acetate (CH_3CO , 19.1%) giving a partially methylated polysaccharide (OMe, 16.2%) from which after repeated methylation with sodium hydroxide and methyl sulphate a product, $[\alpha]_D^{25} + 43^\circ$ (OMe, 18.6; Ca, 3.8; Mg, 0.9; SO_4 , 24.7%), was obtained, the retention of the ethereal sulphate emphasising the stability of that grouping to alkali.

Hydrolysis of the methylated polysaccharide gave a crystalline dimethyl galactose which was identified as 2:6-dimethyl galactose as follows. Oxidation gave a crystalline dimethyl galactonic acid which on distillation yielded a lactone, proved to be a γ -lactone because of its slow hydrolysis in water. A free hydroxyl group was therefore present on C_4 , and this fact was confirmed by the inversion of the sign of rotation of the free sugar on methylgalactofuranoside formation. The amide prepared from the lactone gave a negative Weerman test, proving substitution by methoxyl on C_2 , a fact confirmed on osazone formation since 6-methyl galactosazone (Oldham and Bell, *J. Amer. Chem. Soc.*, 1938, 60, 324) was obtained. Proof of the substitution of the primary alcohol residue by methoxyl was afforded by the fact that no iodine entered the molecule when the ditosyl dimethyl methylgalactoside was treated with sodium iodide in acetone (Oldham and Rutherford, *ibid.*, 1932, 54, 366). The isolation of a crystalline dimethyl monoacetone β -methylgalactopyranoside also proved the presence of free hydroxyl groups on C_3 and C_4 .

The only fact at variance with the proposed assignment of structure was that, although the specific rotations were almost identical, the melting point of 131° for 2:6-dimethyl galactose recorded by Oldham and Bell (*loc. cit.*) was much higher than the value ($119\text{--}120^\circ$) we obtained for our crystalline dimethyl galactose. The facts were re-examined by Dr. D. J. Bell (J., 1945, 692) who repeated and extended the earlier work, and mixed melting point determinations of our dimethyl galactonic acid phenylhydrazide with the corresponding derivative prepared from 2:6-dimethyl galactose, the structure of which had been proved unequivocally both by the synthetic route employed and by periodate oxidation, showed no depression. Furthermore satisfactory agreement was obtained in respect of the melting points of the dimethyl β -methylgalactoside and the corresponding 3:4-monoacetone derivative. It may be recalled that evidence was presented (Part I, *loc. cit.*) that the syrupy dimethyl galactose produced on hydrolysing the methylated *Chondrus crispus* polysaccharides was also 2:6-dimethyl galactose. In these polysaccharide sulphates, therefore, the exposed hydroxyl groups on the galactose residues are on C_2 and C_4 . If we assume that the sulphate groups are directly attached to the galactose residues four possible formulæ must be considered (see opposite page).

It has been shown recently (Percival and Duff, *Nature*, 1946, 158, 29) that barium 3-methyl 1:2-monoacetone glucufuranose 6-sulphate is readily transformed into the corresponding 5:6-anhydride by sodium methoxide. It is highly probable therefore that the sulphate groups

in (B), (C), and (D) would be readily eliminated by alkali, with formation of ethylene oxide rings in the first instance. In addition (B) would also form a 3 : 6-anhydride by analogy with the

methylglucufuranoside 3-sulphates (J., 1945, 119). The most likely arrangement is therefore (A) in which the galactopyranose residues are linked through the 1 and 3 positions as in agar, and it may be that this type of linkage is typical of the galactans of the red seaweeds. The above arguments, based on the resistance to hydrolysis with alkali of the sulphate groups, apply only if these residues are directly attached to the galactose units. It is conceivable, however, that the sulphate groups are attached to those building units (X) of the molecule which have not, as yet, been identified, with these units (X) interposing between the sulphate groups and the triply linked galactose residues. This point could be decided by removing the sulphate groups and following this by methylation, but attempts to remove the sulphate residues have been unsuccessful so far and it seems that a final decision must await the identification of (X).

The substance, or mixture of substances, (X) is clearly not a simple hexose since the methoxyl content of the methylated polysaccharide is only slightly higher than would be required for the dimethyl galactose residues found, and it will be surprising if it contains more than one free hydroxyl group. That (X) might be an anhydro- or a deoxy-sugar has not been lost sight of, but the decomposition it undergoes under acid hydrolytic conditions has prevented progress so far. The hydrolysis of the methylated polysaccharide with methanolic hydrogen chloride was unexpectedly difficult, and only derivatives of methylated galactose could be identified among the products of hydrolysis. In the case of the *Chondrus crispus* polysaccharide, Young and Rice (*J. Biol. Chem.*, 1946, **164**, 35) have isolated diacetone 2-ketogluconic acid in small yield on hydrolysis and treatment with acetone and copper sulphate, but we have not yet succeeded in isolating this material from either the *Chondrus* or the *Gigartina* polysaccharides.

EXPERIMENTAL.

Preparation of the Polysaccharide.—The air-dried seaweed, kindly supplied by Dr. A. P. Orr of the Marine Station, Millport, was washed in muslin bags in 500 g. lots with running water for 10 days. Repeated extraction with water on the steam-bath followed until the extracts were no longer appreciably viscous. The combined extracts were filtered hot and concentrated at 50°/15 mm. to small volume, and the brown viscous solution was added slowly, with mechanical stirring, to ethanol. The white fibrous material was dehydrated with fresh ethanol, washed with ether, and dried in a vacuum desiccator. For all quantitative work the substance was purified by dialysis against running water for six days, filtered, concentrated, reprecipitated, and dried over phosphoric oxide at 50°/15 mm. to constant weight. The product was neutral, non-reducing and had $[\alpha]_D^{25} + 51^\circ$ (c, 0.5 in water) [Found: Ash (as sulphate), 17.6; Ca, 3.6; Mg, 1.0; Na, 0.2; K, 0.1; SO_4 , 23.9%].

Isolation of the Acid Polysaccharide.—The polysaccharide (hereafter designated H.E.) (0.75 g.) in water (50 c.c.) was treated with hydrochloric acid to bring the concentration to N, and the solution in a cellophane bag was dialysed against hydrochloric acid (N) until free from calcium (9 days). Dialysis was continued against distilled water until free from chloride (5 days), and the solution was then diluted to 250 c.c. in a standard flask. By titration against sodium hydroxide (0.05N) to phenolphthalein, the solution was found to be 7.49×10^{-3} N; by weighing the sodium salt obtained on evaporation the equivalent of the sodium salt was calculated as 393 and that of the free acid as 371. The solution of the acid was non-reducing, but became reducing on heating at 100° for 10 minutes; $[\alpha]_D^{25} + 43^\circ$ (c, 0.14 in water) (Found: SO_4 , 25.9%).

Potentiometric Titration.—The table shows a comparison between the titration of the above acid solution (a) against sodium hydroxide (8.22×10^{-3} N) and hydrochloric acid (5.67×10^{-3} N), (b) against sodium hydroxide (5.13×10^{-3} N) using a quinhydrone electrode.

Hydrolyses of H.E.—(1) H.E. (4.98 g.) was hydrolysed at 100° with oxalic acid (210 c.c.; 0.5N) to constant rotation (26 hours, $[\alpha]_D^{25} + 25^\circ$). The solution was decolorised with charcoal, neutralised with calcium carbonate, filtered, and evaporated at 35°/15 mm. to a syrup admixed with calcium sulphate. Extraction with small quantities of water, filtration, and evaporation gave a syrup (4.52 g.). Galactose was determined quantitatively by dissolving the syrup in water (45 c.c.), adding ethanol (45 c.c.), acetic acid (0.5 c.c.), and phenylmethylhydrazine (3.75 c.c.), and keeping at 0° for 4 days. The crystalline galactose phenylmethylhydrazone was filtered off, washed with water, ethanol, and ether, and dried for 3 days in a vacuum over phosphoric oxide, m. p. 186—187° (3.055 g.). Under identical conditions *d*-galactose (3.219 g.) gave galactose phenylmethylhydrazone, m. p. 186° (4.978 g.), *i.e.*, galactose from H.E., 39.6%.

(2) H.E. (11.1 g.) gave galactose phenylmethylhydrazone (6.83 g.), *i.e.*, galactose from H.E., 39.9%.

(3) H.E. (10.23 g.) was heated at 100° with a mixture of oxalic acid (0.1N) and potassium oxalate (400 c.c.; 0.1N) for 26 hours in a nitrogen atmosphere after Young and Rice (*loc. cit.*) and the procedure described by those authors for the isolation of diacetone 2-ketogluconic acid from Irish moss carried out. No identifiable products apart from galactose were obtained.

The filtrates from (1) and (2) were treated with benzaldehyde according to Lüttke (*Biochem. Z.*, 1929, 419) to yield a glass, $[\alpha]_D \pm 0^\circ$ in water, which reduced Fehling's and Barfoed's solution, gave Schiff's test, the Seliwanoff, Bredereck, and selenium dioxide ketose reactions, and the iodoform reaction in the cold; tests for pentoses, methylpentoses, and uronic acids were negative. Salts of organic acids were present, but attempts to isolate esters by treating the free acids with diazomethane followed by methylation were not successful.

Hydrolysis of H.E. with *N*-Sodium Hydroxide at 100°.—H.E. (1.521 g.) was heated with *N*-sodium hydroxide (200 c.c.) at 100° in the presence of barium chloride (1.533 g.). At definite intervals samples (25 c.c.) were withdrawn, water (25 c.c.) and dilute acetic acid (10 c.c.) added, and the solution centrifuged. The residual combined sulphate in 50 c.c. of the solution was then determined by hydrolysis with hydrochloric acid and weighing the barium sulphate produced.

Time, hrs.	4	10	32	56	72
Residual sulphate (BaSO ₄ , mg.)	70.2	65.6	47.4	38.0	34.4
Hydrolysis, %	23	28	48	58	62

Acetylation of H.E.—To H.E. (15.9 g.) dissolved in water (200 c.c.), pyridine (700 c.c.) was added, and the pyridine-water azeotrope distilled off at 50°/15 mm. (Pacsu and Mullen, *loc. cit.*) to a volume of about 250 c.c. To the brown jelly so obtained pyridine (50 c.c.) and acetic anhydride (200 c.c.) were added, slowly, with shaking and cooling. After 12 days at room temperature the acetate was separated at the centrifuge and washed with pyridine, ethanol, and ether. The white powder (18 g.) so produced had $[\alpha]_D^{25} + 46^\circ$ (*c.* 0.8 in water) (Found: CH₃CO, 19.1%).

Deacetylation and Methylation.—The above acetate in water (300 c.c.) was treated with methyl sulphate (120 c.c.) and sodium hydroxide (300 c.c.; 30%) in one-twelfth portions every ½ hour, the temperature being kept below 20°. The solution was then heated to 80° for 30 minutes, cooled, neutralised with acetic acid, and dialysed against running water until sulphate-free (10 days). The dialysed solution was evaporated at 45°/15 mm. to a glass (OMe, 16.2%). This glass was taken up in water (100 c.c.), worked up with pyridine as described above, and reacylated (CH₃CO, 5.9%). Simultaneous deacetylation and methylation as before increased the methoxyl content to 17.2%. This was followed by a third acetylation (CH₃CO, 4.4%) and methylation (OMe, 17.6%), and a fourth acetylation (CH₃CO, 3.5%) and methylation (OMe, 18.2%) (14 g.).

Attempts to increase the methoxyl content of this specimen by three direct methylations with methyl sulphate and sodium hydroxide in the usual way were unsuccessful, as was the application of the thallium method (Hirst *et al.*, *J.*, 1939, 1884).

The methylated polysaccharide was obtained by precipitation from aqueous solution (after dialysis) by ethanol, as a white fibrous solid, $[\alpha]_D^{25} + 43^\circ$ (*c.* 1.6 in water) [Found: Ash (as sulphate), 18.2; Ca, 3.75; Mg, 0.94; Na, 0.31; SO₄, 24.7; OMe, 18.6%].

Hydrolysis of the Methylated Polysaccharide.—The above product (5.13 g.; OMe, 18.6%) was hydrolysed at 100° with oxalic acid (200 c.c., *N*/2) until the rotation was constant ($[\alpha]_D^{25} + 37^\circ$). The solution was neutralised with calcium carbonate and worked up in the usual way to a brown syrup (4.0 g., OMe, 26.3%).

Glycopyranoside Formation.—This syrup was boiled with methanolic hydrogen chloride (160 c.c.; 6%) until non-reducing (8 hours), neutralised with silver carbonate, evaporated, and extracted with ether to give a syrup (2.34 g., OMe, 36.0%, $n_D^{25} 1.4865$) which was fractionated to give (1) 0.09 g., b. p. 100°/0.1 mm., $n_D^{25} 1.4295$; (2) 1.9 g., b. p. 145—155°/0.07 mm., $n_D^{25} 1.4737$, $[\alpha]_D^{25} + 70^\circ$ (*c.* 1.4 in water) (Found: OMe, 40.4. Calc. for C₆H₁₂O₆: OMe, 41.9%). Fraction (1) was identified as methyl laevulate isolated as the dinitrophenylhydrazone, m. p. 136° not depressed on admixture with an authentic specimen.

Preparation of Tetramethyl *d*-Galactopyranose Anilide from (2).—Fraction (2) (0.57 g.) was methylated with methyl sulphate and sodium hydroxide followed by two treatments with Purdie's reagents to give a mobile syrup (0.47 g.), distilled, 90—110°/0.02 mm., to yield a colourless liquid (0.4 g.; $n_D^{25} 1.4495$) which was hydrolysed with sulphuric acid (15 c.c., *N*) at 100° for 6 hours. From the reducing syrup (0.35 g.) isolated in the usual way, treatment with aniline in alcohol gave an anilide (0.23 g., m. p. 193—194°, not depressed by authentic tetramethyl galactopyranose anilide; $[\alpha]_D^{25} - 80^\circ$ (*c.* 0.6 in acetone).

Isolation of Crystalline Dimethyl Galactose.—Fraction (2) (0.81 g.) was hydrolysed with sulphuric acid (30 c.c.; *N*) for 5 hours, $[\alpha]_D^{25} + 82^\circ$. Neutralisation with barium carbonate, filtration, and evaporation gave a crystalline product (0.65 g.), m. p. 119—120° after three recrystallisations from dry ethyl acetate, $[\alpha]_D^{25} + 48^\circ$ (10 mins.), + 87° (240 mins., constant; *c.* 0.67 in water) (Found: C, 46.5; H, 7.5; OMe, 29.1. Calc. for C₆H₁₂O₆: C, 46.2; H, 7.7; OMe, 29.8%). Normally crystallising as needles, this

dimethyl galactose was obtained in the form of large plates from ethyl acetate–light petroleum (b. p. 40–60°).

Isolation of 6-Methyl Galactosazone.—The free sugar (0.34 g.) in water (5 c.c.) gave several crops (0.26 g.) of an osazone which on recrystallisation had m. p. 201–203° not depressed by authentic 6-methyl galactosazone (Found: OMe, 7.1. Calc. for $C_{10}H_{24}O_4N_4$: OMe, 8.3%).

Galactofuranoside Formation.—The sugar in methanolic hydrogen chloride (1%; c, 1.675) showed the following rotational changes (time in hours): $[\alpha]_D^{25} + 42^\circ$ (0.75); 23° (18); 12.5° (25); – 9.5° (42); – 15.5° (48); – 29° (66); – 39° (92); – 43° (114; constant).

Evidence for Substitution on C₆.—Fraction (2) was treated with an excess of toluene-*p*-sulphonyl chloride in pyridine to yield a syrupy product, $[\alpha]_D^{25} + 32^\circ$ (c, 2.3, in chloroform) (Found: OMe, 15.5. $C_{10}H_{20}O_5S_2$ requires OMe, 17.6%).

Treatment with sodium iodide in acetone according to Oldham and Rutherford (*loc. cit.*) gave a product devoid of iodine. Oxidation of the crystalline dimethyl galactose with sodium periodate gave no formaldehyde.

Derivatives of 2:6-Dimethyl Galactose.—2:6-Dimethyl galactonic acid. The dimethyl galactose (1.59 g.) in water (25 c.c.) was treated with bromine (1.75 c.c.) at room temperature until non-reducing (6 days). After aeration, neutralisation with silver carbonate, and treatment with hydrogen sulphide, etc., a viscous syrup (1.66 g.), $[\alpha]_D^{25} + 26^\circ$ (c, 1.6 in water), was obtained (Found: C, 42.5; H, 7.1; OMe, 24.8. $C_8H_{14}O_7$ requires C, 42.9; H, 7.2; OMe, 27.7%).

2:6-Dimethyl γ -galactonolactone. The above crystalline acid (0.96 g.) distilled at 180°/0.02 mm. to give a syrup (0.9 g.), $n_D^{20} 1.4760$, $[\alpha]_D^{25} - 49^\circ$ (initial); – 24° (28 days; c, 1.09 in water) (Found: OMe, 28.6; equiv., 205. Calc. for $C_8H_{14}O_6$: OMe, 30.1%; equiv., 206). Titration with sodium hydroxide was characteristic of a γ -lactone.

2:6-Dimethyl galactonamide. The above lactone (0.34 g.) was treated with methanolic ammonia (5 c.c.) at 0° for 2 days; removal of solvent gave a crystalline amide (0.365 g.) which after three recrystallisations from ethanol gave small needles, m. p. 154–155°, $[\alpha]_D^{25} + 46^\circ$ (c, 0.85, in water) (Found: C, 43.5; H, 7.3; N, 6.0; OMe, 26.7. $C_{10}H_{21}O_5N$ requires C, 43.1; H, 7.7; N, 6.3; OMe, 27.8%). This amide (0.1 g.) gave a negative Weerman reaction.

2:6-Dimethyl galactonic acid phenylhydrazide. The lactone (0.2 g.) was allowed to react with phenylhydrazine (1 mol.) in boiling ether for 15 minutes. On removing the solvent and heating at 85–90° for 2 hours, a crystalline product was obtained which was recrystallised (0.25 g.) from ethanol–ether, m. p. 140° alone and admixed with an authentic specimen of 2:6-dimethyl galactonic acid phenylhydrazide supplied by Dr. D. J. Bell (Found: C, 53.1; H, 7.2; N, 8.9; OMe, 19.0. Calc. for $C_{14}H_{23}O_5N_2$: C, 53.5; H, 7.1; N, 8.9; OMe, 19.8%).

2:6-Dimethyl β -methyl- α -galactoside. The dimethyl galactose (0.5 g.) was acetylated at room temperature with pyridine and acetic anhydride in the usual way to give a crystalline acetate which was treated with hydrogen bromide in acetic acid followed by silver carbonate and methanol to give a non-reducing syrup (0.66 g.), $[\alpha]_D^{25} + 19^\circ$ (c, 6.6 in chloroform). This was deacetylated with sodium hydroxide (0.1N) and the product distilled at 145–150°/0.05 mm. to give a syrup (0.38 g.), $n_D^{20} 1.4763$, which crystallised on standing. After two recrystallisations from ether–light petroleum (b. p. 40–60°), hygroscopic needles, m. p. 72°, were obtained, $[\alpha]_D^{25} - 22^\circ$ (c, 0.9 in chloroform) (*cf.* Bell, *loc. cit.*) (Found: OMe, 41.0. Calc. for $C_9H_{17}O_6$: OMe, 41.9%).

2:6-Dimethyl 3:4-monoacetone β -methylgalactoside. The mother liquors from the above recrystallisations were evaporated to a syrup which crystallised slowly (0.2 g.) and was dissolved in dry acetone (50 c.c.) and shaken for 4 days with anhydrous copper sulphate (2 g.). After the usual treatment, distillation at 100°/0.1 mm. gave a crystalline product, m. p. 55° (*cf.* Bell, *loc. cit.*) (Found: OMe, 34.5. Calc. for $C_{12}H_{22}O_6$: OMe, 35.5%).

2:6-Dimethyl galactose anilide. The dimethyl galactose (0.31 g.) in ethanol (7 c.c.) was heated with aniline (1 mol.) at 80° for 3.5 hours to give a crystalline anilide (0.42 g.). Three recrystallisations from ethanol gave needles, m. p. 121–122°, $[\alpha]_D^{25} + 15^\circ$ (c, 0.7 in ethanol) (Found: N, 5.2; OMe, 22.2. $C_{14}H_{21}O_5N$ requires N, 4.9; OMe, 21.9%). A satisfactory elementary analysis for carbon could not be obtained from this material (*see also* Bell, *loc. cit.*).

Hydrolysis of Methylated H.E. followed by Furanoside Formation.—Methylated H.E. (5.23 g.; OMe, 18.6%) was hydrolysed with oxalic acid (0.5N) as before to give a syrup (3.54 g.) which was treated with methanolic hydrogen chloride (100 c.c.; 2%) at room temperature. After 8 days the solution was non-reducing ($[\alpha]_D^{25} - 30^\circ$ (c, 0.7)). Neutralisation with silver carbonate, etc., gave a syrup (2.75 g.) which was distilled in the presence of barium carbonate, giving: (1) 0.05 g., b. p. 100°/15 mm., $n_D^{20} 1.4302$; (2) 1.98 g., b. p. 120–145°/0.04 mm., $[\alpha]_D^{25} - 35^\circ$ (c, 3.8; in water), $n_D^{20} 1.4672$ (OMe, 39.0%); (3) 0.3 g., b. p. 145–165°/0.02 mm., $n_D^{20} 1.4710$; (4) 0.13 g., b. p. 165–205°/0.02 mm., $n_D^{20} 1.4813$, $[\alpha]_D^{25} - 8^\circ$ (c, 1.1 in water) (OMe, 33.9%). Fraction (2) was a mixture of 2:6-dimethyl methylgalactofuranosides and gave on hydrolysis (1.66 g.) crystalline 2:6-dimethyl galactose (1.2 g.), m. p. 110° without recrystallisation. Fraction (4) was thought to be an impure monomethyl methylgalactoside, but attempts to secure evidence of this by osazone formation were not successful.

Hydrolysis of Methylated H.E. with Methanolic Hydrogen Chloride.—Methylated H.E. (4.65 g.; OMe, 20.2%) was heated with methanolic hydrogen chloride (200 c.c.; 1.2%) for 24 hours in the presence of barium chloride (5.1 g.). After neutralisation with barium carbonate a non-reducing glass (4.1 g.) was isolated which still contained sulphur (OMe, 33.5%); this was boiled for 16 hours with methanolic hydrogen chloride (100 c.c.; 2%) in the presence of barium chloride. After neutralisation and suitable treatment an ether-soluble fraction (A) (1.15 g.) and a glass (B) (2.6 g.) were isolated. (B) was further hydrolysed for 24 hours with methanolic hydrogen chloride (100 c.c.; 2.7%) and barium chloride from which an ether-soluble fraction (C) (0.23 g.) and an ethanol-soluble fraction (D) (2.1 g.; OMe, 32.0%) were obtained. (A) and (C) were combined and distilled at 135–155°/0.05 mm. to give mainly 2:6-dimethyl methylgalactosides (1.11 g.), $n_D^{20} 1.4748$ (OMe, 38.1%), which gave crystalline 2:6-dimethyl galactose in good yield on hydrolysis.

Fraction (D) (1.75 g.) was dissolved in methano and methylated five times with silver oxide and

methyl iodide. Distillation gave: (1) 0.79 g., b. p. 90—95°/0.02 mm., n_D^{17} 1.4481 (OMe, 57.6%); (2) 0.54 g., b. p. 95—100°/0.02 mm., n_D^{17} 1.4478 (OMe, 56.9%); (3) 0.12 g., b. p. 100—125°/0.02 mm., n_D^{17} 1.4483 (OMe, 55.3%).

Fraction (1) (0.43 g.) was hydrolysed with sulphuric acid (N) and the reducing syrup (0.3 g.) treated with aniline in ethanol to give tetramethyl *d*-galactopyranose anilide (0.14 g.), m. p. 195°, $[\alpha]_D^{16}$ — 78° (c, 0.7 in acetone). The other component of the mixture could not be identified.

Fractions (1), (2), and (3) (0.9 g.) were combined, and, after hydrolysis and treatment with aniline, tetramethyl *d*-galactopyranose anilide (0.3 g.), m. p. 196—197°, $[\alpha]_D^{18}$ — 81° (c, 0.7 in acetone), was obtained. No other products could be identified.

A further hydrolysis with methanolic hydrogen chloride (4%, in nitrogen) resulted in the isolation after a chromatographic separation on aluminium oxide of 2:6-dimethyl galactose, m. p. 112° (30%). No other identifiable products could be isolated, and a search for methylated derivatives of 2-ketogluconic acid after complete methylation was abortive.

Thanks are expressed to Dr. A. P. Orr, Marine Biological Station, Millport, for the gift of material, to Dr. D. J. Bell for specimens, and to Imperial Chemical Industries Ltd. and the Earl of Moray Endowment for grants.

KING'S BUILDINGS, UNIVERSITY OF EDINBURGH.

[Received, February 4th, 1947.]

324. The Reaction of $\alpha\beta$ -Ethyne Ketones with Active Methyl and Methylene Compounds.

By A. W. JOHNSON.

The reaction of acyl- or aroyl-acetylenes (2 mols.) and pyridines containing a 4-methyl or methylene group yields violet adducts which are represented by structures such as (III). An active "zwitterion" formed from 2 mols. of the ethynyl ketone is postulated as the intermediate in these and similar reactions. With 1:3:3-trimethylindolenine methiodide, the acyl- or aroyl-acetylenes give, after the addition of alkali, adducts formed from equimolecular quantities of the reactants, but the corresponding reaction with 2-methylbenzthiazole ethiodide resembles those with the pyridines in that 2 mols. of the ketone react with each mol. of base. The addition of ethynyl ketones to nitrogen heterocyclic compounds containing active methylene groups, e.g., 1-phenyl-3-methyl-5-pyrazolone, and active methine groups, e.g., 2:4-diphenylpyrrole and 2-methylindole, is also described.

In the course of other work on the reactions of the $\alpha\beta$ -ethynyl ketones, $R\cdot CO\cdot C\equiv CH$, it was observed that when phenyl ethynyl ketone (Bowden, Heilbron, Jones, and Weedon, *J.*, 1946, 39) was dissolved in either methylated spirits or industrial absolute alcohol, a deep violet colour rapidly developed on warming, or more slowly at room temperature. This colour was not obtained with methyl alcohol or denaturant-free alcohol. A sample of alcohol denaturant was therefore obtained and fractionated, and the colour shown to be associated with the presence of pyridine bases. Attention was then turned to the reaction of individual specially purified pyridine and quinoline homologues (0.5 c.c.) with phenyl ethynyl ketone (0.05 g.) in methyl alcohol (2 c.c.), and the following colours were observed:

Base.	Purification.	Colour.
Pyridine	Fractionation	Pale yellow
α -Picoline	Regeneration from $HgCl_2$ adduct, m. p. 153—154°	Dark reddish-brown
β -Picoline	Regeneration from oxalate, ¹ m. p. 108—109°	Pale yellow
γ -Picoline	Regeneration from oxalate, ² m. p. 139—140°	Intense reddish-violet; crystals separated on standing
4-Ethylpyridine	Fractionation ³ (synthetic)	Intense reddish-violet; crystals separated on standing
2:4-Lutidine	Regeneration from $HgCl_2$ adduct, ^{1,4} m. p. 117—119°	Intense reddish-violet; no separation of solid
2:6-Lutidine	Regeneration from $HgCl_2$ adduct, ¹ m. p. 187—189°	Pale pink
Quinaldine	Fractionation	Pale yellow
Lepidine	Fractionation (synthetic)	Orange-red

¹ Lidstone, *J.*, 1940, 241.

² Kolloff and Hunter, *J. Amer. Chem. Soc.*, 1941, 63, 490.

³ Wibaut and Arens, *Rec. Trav. chim.*, 1941, 60, 119.

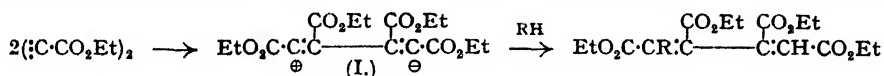

⁴ Bratton and Bailey, *J. Amer. Chem. Soc.*, 1937, 59, 177.

It was therefore apparent that the coloration observed in alcoholic solutions of phenyl ethynyl ketone was due to the presence of pyridine homologues containing active (*i.e.*, α - or γ -)

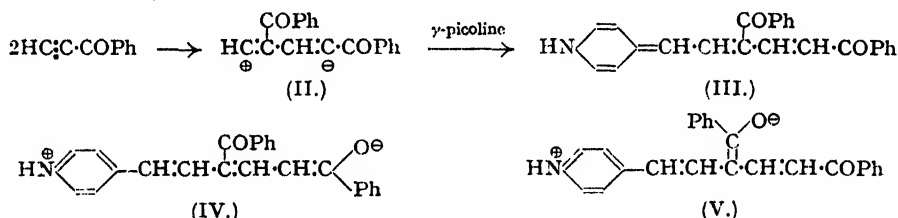

methyl or methylene groups and that violet colorations were to be particularly associated with the γ -substituted pyridines. The colour produced from the reaction of γ -picoline with phenyl ethynyl ketone proved to be sufficiently sensitive to detect 2 p.p.m. of the base in methyl alcohol. Attempts were made to apply the colour reaction to the quantitative determination of α -picoline in pyridine (γ -picoline may be readily separated from pyridine by fractionation), but the reaction proved to be less sensitive in the case of the α -isomer, and other methods for the estimation of α -picoline were found to be preferable.

Purification and analyses of the violet adduct from γ -picoline and phenyl ethynyl ketone indicated a molecular formula, $C_{24}H_{19}O_2N$ (i.e., $2C_9H_6O, C_6H_7N$), and this was supported by the almost quantitative yield of the adduct obtained on mixing 2 mols. of phenyl ethynyl ketone with 1 mol. of γ -picoline in a small volume of methyl alcohol. The same adduct was obtained when other alcoholic solvents, e.g., 2-ethoxyethanol, were used as solvents for the reaction, but in non-polar solvents such as ether or benzene mixtures of products were formed.

It is probable that the reaction of ethynyl ketones with γ -picoline and similar compounds closely resembles those described by Diels and his co-workers (*Annalen*, 1932, 498, 16; 1933, 505, 103; 1934, 510, 87; 513, 129; 1935, 516, 45; 519, 140; 1936, 525, 73; 1937, 530, 68; 1939, 543, 79; 1944, 556, 38; *J. pr. Chem.*, 1940, 156, 195; *Ber.*, 1942, 75, 1452) in which ethyl acetylenedicarboxylate was caused to react with a variety of heterocyclic bases. It was postulated that the zwitterion (I) was an intermediate which reacted with the base as shown:

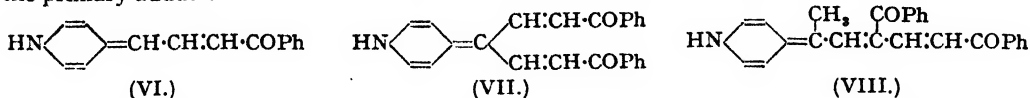

In the case of phenyl ethynyl ketone the active intermediate would be (II) by analogy, giving (III) on addition to γ -picoline:

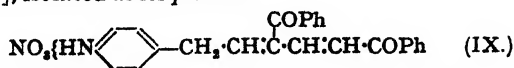

The intense violet colour of the adduct is probably due to the resonance between (III) and structures such as (IV) and (V).

A further example of phenyl ethynyl ketone reacting in the zwitterion form was encountered in the reaction with ammonium acetate in acetic acid solution, 5-benzoyl-2-phenylpyridine being obtained (cf. Bowden and Jones, *J.*, 1946, 953) together with *s*-tribenzoylbenzene.

Another possible mechanism for the reaction is that the compound (VI) is the intermediate in the reaction, in which case the final adduct could be (III) or (VII). Of the two mechanisms, the former is preferred, for it will be shown later that 2:3:3-trimethylindolenine methiodide reacts with only 1 equiv. of ethynyl ketones to give adducts of the type (VI) after the addition of potassium acetate, and in no case could a second equiv. of ethynyl ketone be induced to add to the primary adduct.

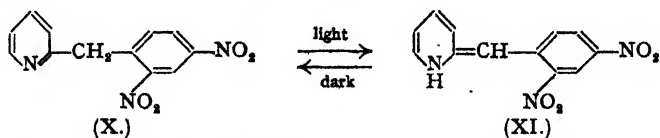

Nevertheless, structure (VII) has been eliminated on chemical grounds, for it was shown that the reaction of 4-ethylpyridine (Wibaut and Arens, *loc. cit.*) with phenyl ethynyl ketone in methanolic solution readily gave the violet adduct (VIII). The accepted structure (III) for the adduct of γ -picoline and phenyl ethynyl ketone was further supported by oxidative degradation. Oxidation with 50% nitric acid gave benzoic acid (2 mols.) and isonicotinic acid (1 mol.) [i.e., from the nitric acid salt (IX)], isolated as its *picrate*.

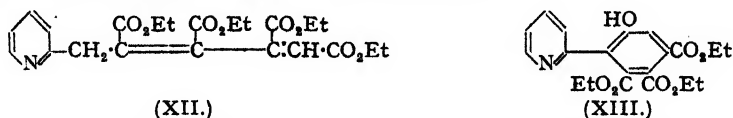

Analogues of (III) have been prepared by reaction of γ -picoline with methyl ethynyl ketone, *m*-methoxyphenyl ethynyl ketone, and *o*-chlorophenyl ethynyl ketone, severally. With phenyl

1-hexynyl ketone and γ -picoline in methanolic solution a deep blue solution was obtained but the adduct was an oil. Stable pyridine methide compounds containing no nitrogen substituents are uncommon, but Tschitchibabin, Kuindshi and Benewolenskaya (*Ber.*, 1925, 58, 1580) have shown that the yellow compound (X) is converted into the purple isomer (XI) on irradiation. The reverse change occurs in the absence of light.

Diels and Pistor (*Annalen*, 1937, 530, 87) have shown that α -picoline reacts with ethyl acetylenedicarboxylate in ethereal solution to give some of a dark red adduct formulated as (XII), which was converted into (XIII) on refluxing with methyl alcohol. No mention was made of the possibility of (XII) being in the quinonoid form.

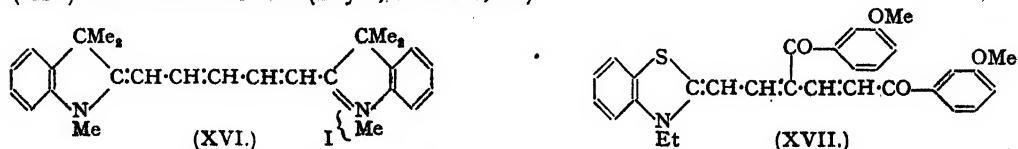

The reaction of $\alpha\beta$ -ethynyl ketones with quaternary salts containing active methyl groups has also been investigated. Phenyl ethynyl ketone with 2:3:3-trimethylindolenine methiodide, after the addition of potassium acetate to remove the elements of hydrogen iodide, gave a red crystalline compound, m. p. 158–159°, which contained no iodine, had the constitution $C_{21}H_{21}ON$, and was formulated as (XIV; R = Ph).

This formulation was supported by the almost quantitative yield of (XIV) obtained on mixing equimolecular quantities of the reactants in methyl alcohol and by the oxidation of the adduct with 50% nitric acid, whereupon 4:6-dinitro-1:3:3-trimethyloxindole (XV) (Beilstein, "Handbuch der Organischen Chemie", 21, 294; Brunner, *Monatsh.*, 1896, 17, 266) was obtained in good yield. Analogues of (XIV; R = Me and *m*-MeO·C₆H₄) have been prepared from trimethylindolenine methiodide with methyl ethynyl ketone and *m*-methoxyphenyl ethynyl ketone, respectively.

A second mol. of phenyl ethynyl ketone could not be added to (XIV) to form an adduct analogous to (III) (*e.g.*, on heating an alcoholic solution in the presence of a small amount of sodium hydroxide or piperidine or on heating in acetic anhydride) and (XIV) was always formed from the condensation of 2:3:3-trimethylindolenine methiodide and phenyl ethynyl ketone, however the ratio of the reactants was varied. The corresponding condensation of the diethylacetal of propionic aldehyde with 2:3:3-trimethylindolenine methiodide gives rise to the indocarbocyanine dyestuff, Astrophloxine FF (XVI), and the intermediate corresponding to (XIV) has not been isolated (Bayer, G.P. 410,487).

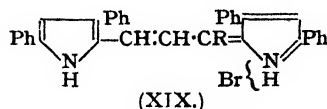

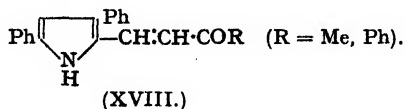

Attempts to condense (XIV; R = Me, Ph) with a second mol. of 2:3:3-trimethylindolenine methiodide have not been successful.

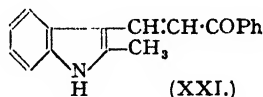

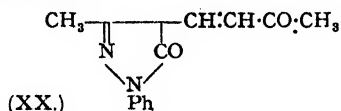

The reaction of 2-methylbenzthiazole ethiodide with *m*-methoxyphenyl ethynyl ketone in the presence of potassium acetate gave a moderate yield of the red adduct (XVII), in which 2 mols. of the ketone had reacted with each mol. of the base, but highly coloured products were not obtained from similar reactions with the ethiodides of 2-methylbenzoxazole or 2-methylbenziminazole. With quinadine and lepidine ethiodides, dark blue adducts were obtained from the

reaction with phenyl ethynyl ketone in methyl-alcoholic solution in the presence of potassium acetate, but the structure of the products has not yet been fully elucidated and will be described in a later paper.

$\alpha\beta$ -Ethyne ketones have also been added to active methylene and methine groups of certain nitrogen heterocyclic compounds. No basic catalyst is required to effect the addition which takes place merely on refluxing the reactants together in methyl-alcoholic solution. With 2 : 4-diphenylpyrrole (Rogers, *J.*, 1943, 590) adducts of the type (XVIII) are readily obtained, the structure of which has been proved by condensation with a further mol. of 2 : 4-diphenylpyrrole in the presence of acids to give the highly coloured salts (XIX) (Cook and Majer, *J.*, 1944, 482).

The reaction of 1-phenyl-3-methyl-5-pyrazolone and methyl ethynyl ketone gave (XX), identical with the product obtained by Gaspar (B.P. 515,998) by the condensation of the pyrazolone with sodio-formylacetone. The addition of phenyl ethynyl ketone to 2-methylindole gave an adduct formulated as (XXI) by analogy with the additions of maleic anhydride (Diels, Alder, and Lübbert, *Annalen*, 1931, 490, 277) and *p*-benzoquinone (Möhlau and Redlich, *Ber.*, 1911, 44, 3605).

EXPERIMENTAL.

(M. p.s are uncorrected, and micro-analyses were carried out by Mr. E. S. Morton.)

4-(3' : 5'-Dibenzoylpenta-2' : 4'-dienylidene)-1 : 4-dihydropyridine (III).— γ -Picoline (2.8 g.; regenerated from the oxalate) in methyl alcohol (10 c.c.) was added dropwise with stirring to a solution of phenyl ethynyl ketone (8.0 g.; Bowden, Heilbron, Jones, and Weedon, *loc. cit.*) in methyl alcohol (20 c.c.), the temperature being kept below 30°. The solution became red and then red-violet and the solid adduct was deposited almost immediately. After standing for 3 hours, the solid (10.1 g.) was separated and washed with cold methyl alcohol (20 c.c.). Rapid crystallisation from 2-ethoxyethanol gave 4-(3' : 5'-dibenzoylpenta-2' : 4'-dienylidene)-1 : 4-dihydropyridine as red-violet needles, m. p. 202–203°. Prolonged boiling of 2-ethoxyethanol solutions caused decomposition, and small quantities of the adduct may be conveniently crystallised from methyl alcohol (Found: C, 81.3; H, 5.4; N, 3.85, 4.05. $\text{C}_{24}\text{H}_{19}\text{O}_2\text{N}$ requires C, 81.6; H, 5.4; N, 4.0%). In order to obtain satisfactory carbon analyses in this series, it was necessary to mix copper oxide with the sample for combustion. Light absorption: maximum 5250 Å., ϵ max. 6920. The adduct formed an orange solution in concentrated sulphuric acid and the red-violet methyl-alcoholic solution of the adduct was turned pink by the addition of dilute acids. The solution was unchanged in colour on addition of 2N-sodium hydroxide or 2N-ammonium hydroxide but turned yellow on addition of 10N-sodium hydroxide solution.

4-(3' : 5'-Dibenzoyl-1'-methylpenta-2' : 4'-dienylidene)-1 : 4-dihydropyridine (VIII).—4-Ethylpyridine (0.82 g.; Wibaut and Arens, *Rec. Trav. chim.*, 1941, 60, 119) in methyl alcohol (2 c.c.) was added to phenyl ethynyl ketone (2 g.) in methyl alcohol (8 c.c.). The solution rapidly became red-violet and heat was evolved. After standing overnight, the crude solid, m. p. 217–219° (1.6 g.), was separated and crystallised from methyl alcohol (500 c.c.) to yield 4-(3' : 5'-dibenzoyl-1'-methylpenta-2' : 4'-dienylidene)-1 : 4-dihydropyridine, m. p. 232–233° (Found: C, 81.6; H, 5.7; N, 4.1. $\text{C}_{25}\text{H}_{21}\text{O}_2\text{N}$ requires C, 81.8; H, 5.7; N, 3.8%).

4-(3' : 5'-Di-*m*-methoxybenzoylpenta-2' : 4'-dienylidene)-1 : 4-dihydropyridine. — γ -Picoline (0.3 g.) in methyl alcohol (1 c.c.) was added to a solution of *m*-methoxyphenyl ethynyl ketone (1.0 g.; Johnson and Melhuish, this vol., p. 346) in methyl alcohol (5 c.c.). The mixture rapidly acquired a red-violet coloration with evolution of heat. After standing overnight, the solid (1.1 g.) was separated, washed with methyl alcohol, and crystallised from 2-ethoxyethanol, 4-(3' : 5'-di-*m*-methoxybenzoylpenta-2' : 4'-dienylidene)-1 : 4-dihydropyridine being obtained as red-violet needles, m. p. 195–196° [Found: C, 75.1; H, 5.75; OCH_3 , 14.7. $\text{C}_{24}\text{H}_{19}\text{O}_4\text{N}$ requires C, 75.5; H, 5.6; OCH_3 , 15.0%).

4-(3' : 5'-Di-*o*-chlorobenzoylpenta-2' : 4'-dienylidene)-1 : 4-dihydropyridine. — γ -Picoline (0.3 g.) and *o*-chlorophenyl ethynyl ketone (1.0 g.; see below for preparation) under the conditions of the previous experiment afforded 4-(3' : 5'-di-*o*-chlorobenzoylpenta-2' : 4'-dienylidene)-1 : 4-dihydropyridine (1.0 g.), which crystallised from 2-ethoxyethanol (5 c.c.) as violet needles, m. p. 140–141° (Found: Cl, 16.9. $\text{C}_{24}\text{H}_{17}\text{O}_2\text{NCl}_2$ requires Cl, 16.8%).

4-(3' : 5'-Diacylpenta-2' : 4'-dienylidene)-1 : 4-dihydropyridine. — γ -Picoline (0.7 g.) in methyl alcohol (1.0 c.c.) was added to a solution of methyl ethynyl ketone (1.0 g.; Bowden, Heilbron, Jones, and Weedon, *loc. cit.*) in methyl alcohol (2 c.c.) with external cooling. A vigorous reaction occurred and the solution became reddish-brown. 4-(3' : 5'-Diacylpenta-2' : 4'-dienylidene)-1 : 4-dihydropyridine rapidly

separated and after standing overnight it was collected (1.4 g.) and crystallised from methyl alcohol, forming reddish-brown needles, m. p. 202—203° (Found: C, 73.0; H, 6.75; N, 5.7. $C_{14}H_{11}O_2N$ requires C, 73.35; H, 6.55; N, 6.1%).

o-Chlorophenylethyne carbinol.—Purified acetylene was rapidly passed into liquid ammonia (1000 c.c.) with stirring and cooling, and sodium (23 g.) added in small pieces at such a rate that the blue colour never persisted for more than few moments. A solution of *o*-chlorobenzaldehyde (140 g.; redistilled) in ether (150 c.c.) was added dropwise during 1½ hours, and the mixture was stirred and cooled for a further 3 hours with continued introduction of acetylene. The ammonia was allowed to evaporate overnight and ether and dilute hydrochloric acid (ice) were added to the residue. Isolation of the product in the usual manner gave *o*-chlorophenylethyne carbinol as a pale yellow liquid (73 g.), b. p. 147—148°/26 mm.; n_D^{20} 1.5669 (Found: C, 64.55; H, 4.05. C_8H_7OCl requires C, 64.85; H, 4.2%). In one experiment, *o*-chlorobenzyl alcohol, b. p. 120—125°/18 mm., m. p. 71—72°, formed by a simultaneous Cannizzaro reaction, was isolated from the lower-boiling fractions of the distillation, and it is therefore important not to add the aldehyde too quickly to the sodium acetylide solution.

o-Chlorophenyl Ethynyl Ketone.—To a stirred solution of *o*-chlorophenylethyne carbinol (68 g.) in acetone (80 c.c.), a solution of chromium trioxide (38 g.) in water (120 c.c.) was slowly added in an atmosphere of nitrogen, the temperature of the solution being kept below 15°. After a further hour's stirring, the mixture was poured into water (1000 c.c.) and extracted with ether (3 × 200 c.c.). Evaporation of the ethereal solution gave a yellow solid which recrystallised from petroleum (b. p. 60—80°) to give *o*-chlorophenyl ethynyl ketone (41 g.) as pale yellow needles, m. p. 67—68° (Found: C, 65.45; H, 3.3. C_8H_5OCl requires C, 65.65; H, 3.05%). The ketone readily formed a red insoluble copper derivative and a white insoluble silver derivative.

Phenyl 1-Hexynyl Ketone.—A solution of chromium trioxide (9 g.) in water (28 c.c.) and concentrated sulphuric acid (7.5 c.c.) was added dropwise during 1 hour with stirring to 1-phenyl-2-hexyn-1-ol (18.2 g.; Campbell, Campbell, and McGuire, *Chem. Abs.*, 1941, 35, 5872) in acetone (30 c.c.), the reaction temperature being kept below 15°. The mixture was further stirred for 1 hour at room temperature and then poured into water (300 c.c.), and the product isolated by means of ether. Distillation of the residue after removal of the solvent gave *phenyl 1-hexynyl ketone* as a pale yellow liquid (12.6 g.), b. p. 104°/1 mm.; n_D^{20} 1.5451 (Found: C, 83.5; H, 7.2. $C_{13}H_{14}O$ requires C, 83.85; H, 7.5%).

Oxidation of 4-(3':5'-Dibenzoylpenta-2':4'-dienylidene)-1:4-dihydroxyridine.—The adduct (III) (1.0 g.) was treated with nitric acid (25 c.c.) and water (25 c.c.) and refluxed for 3 hours. Nitrous fumes were evolved and the final solution was clear yellow. After standing overnight, benzoic acid (0.4 g.), m. p. 120—121° after sublimation, was deposited and was separated. The filtrate was concentrated, and on cooling, a further amount of benzoic acid (0.1 g.) was obtained, which was again separated. The filtrate was diluted with water (5 c.c.) and again concentrated, and this process repeated in order to remove the excess of nitric acid. The residue was again diluted with water (5 c.c.) and the filtered solution extracted with ether (3 × 5 c.c.). The aqueous layer was treated with excess of picric acid solution and the first-formed low-melting precipitate removed. After standing overnight, isonicotinic acid picrate separated as stout yellow needles (0.25 g.), m. p. 214—215° after crystallisation from water (Found: C, 40.65; H, 2.45; N, 15.85. $C_{12}H_8O_6N_4$ requires C, 40.6; H, 2.3; N, 15.8%). The m. p. of this derivative was not depressed on admixture with an authentic specimen, prepared from the isonicotinic acid obtained by permanganate oxidation of γ -picoline (Koelsch, *J. Amer. Chem. Soc.*, 1943, 65, 2464). A mixture of isonicotinic acid picrate with nicotinic acid picrate, m. p. 210—211° (Found: C, 40.6; H, 2.7%), had m. p. 186—199°.

1:3:3-Trimethyl-2-(3'-benzoylallylidene)dihydroindole (XIV; R = Ph).—Phenyl ethynyl ketone (4.4 g.) in methyl alcohol (10 c.c.) was added to a solution of 2:3:3-trimethylindolenine methiodide (10 g.) in methyl alcohol (60 c.c.) and the mixture refluxed for 1 minute. A solution of potassium acetate (3.4 g.) in methyl alcohol (6 c.c.) was added to the yellow solution, which rapidly became red. After standing for 3 hours, the precipitated 1:3:3-trimethyl-2-(3'-benzoylallylidene)dihydroindole (9.0 g.; 89%) was separated, and crystallised from methyl alcohol in orange-red prisms, m. p. 158—159° (Found: C, 82.9; H, 7.2; N, 4.95. $C_{21}H_{21}ON$ requires C, 83.15; H, 6.9; N, 4.6%). Light absorption: maximum 4600 Å., ϵ max. 45,100.

1:3:3-Trimethyl-2-pent-2'-en-4'-onylidenedihydroindole (XIV; R = Me).—Methyl ethynyl ketone (0.46 g.) in methyl alcohol (2 c.c.) was added to a solution of 2:3:3-trimethylindolenine methiodide (2 g.) in methyl alcohol (15 c.c.), and the mixture warmed slightly. A solution of potassium acetate (0.34 g.) in methyl alcohol (2 c.c.) was added, and the solution immediately became dark yellow. After standing overnight, the adduct was precipitated by cautious addition of water. 1:3:3-Trimethyl-2-pent-2'-en-4'-onylidenedihydroindole crystallised from 50% aqueous methyl alcohol in long yellow needles, m. p. 130—131° (Found: C, 79.45; H, 7.7; N, 6.05. $C_{18}H_{18}ON$ requires C, 79.65; H, 7.9; N, 5.8%). Light absorption: maximum 4150 Å., ϵ max. 45,800.

1:3:3-Trimethyl-2-(3'-*m*-methoxybenzoylallylidene)dihydroindole (XIV; R = *m*-MeO·C₆H₄).—*m*-Methoxyphenyl ethynyl ketone (1.08 g.) in methyl alcohol (5 c.c.) was added to a solution of 2:3:3-trimethylindolenine methiodide (2 g.) in methyl alcohol (15 c.c.), and the mixture refluxed for 1 minute. A solution of potassium acetate (0.7 g.) in methyl alcohol (5 c.c.) was added, after which the solution acquired a deep red colour and the solid adduct was rapidly deposited. After standing for 3 hours, 1:3:3-trimethyl-2-(3'-*m*-methoxybenzoylallylidene)dihydroindole (2.0 g.) was separated, washed, and crystallised from methyl alcohol (300 c.c.), forming bright red plates, m. p. 182—183° (Found: C, 78.7; H, 6.5; N, 4.85. $C_{22}H_{22}O_2N$ requires C, 78.7; H, 6.5; N, 4.8%). Light absorption: maximum 4600 Å., ϵ max. 46,300.

Oxidation of 1:3:3-Trimethyl-2-(3'-benzoylallylidene)dihydroindole.—The adduct (XIV; R = Ph) (1 g.) was treated with nitric acid (d 1.42; 25 c.c.) and water (25 c.c.) and the mixture refluxed for 3 hours. Nitrous fumes were evolved and the black tar at first produced slowly dissolved and a yellow solution was formed. After cooling, the solution was made alkaline to brilliant-yellow, any solid separated, and the solution extracted with ether (3 × 50 c.c.). Removal of the ether gave a pale brown solid (0.37 g.) which was crystallised from methyl alcohol and then from a small volume of toluene to

gave 4:6-dinitro-1:3:3-trimethyloxindole as pale yellow plates, m. p. 146—147° (Brunner, *loc. cit.*, gives m. p. 148°), alone and mixed with an authentic specimen.

3-Ethyl-2-(3':5'-di-m-methoxybenzoylpenta-2':4'-dienylidene)benzthiazoline (XVII).—*m*-Methoxyphenyl ethynyl ketone (0.52 g.) in methyl alcohol (5 c.c.) was added to a solution of 2-methylbenzthiazole ethiodide (1 g.) in methyl alcohol (5 c.c.), and the mixture warmed slightly. A solution of potassium acetate (0.32 g.) in methyl alcohol (3 c.c.) was added, whereupon the solution became deep red and a solid adduct, m. p. 150—154°, was deposited after standing overnight. The adduct (0.2 g.) was repeatedly crystallised from 2-ethoxyethanol to yield 3-ethyl-2-(3':5'-di-m-methoxybenzoylpenta-2':4'-dienylidene)-benzthiazoline as small red needles, m. p. 171—172° (Found: C, 72.5; H, 5.25; N, 2.9; S, 6.05. $C_{20}H_{22}O_4NS$ requires C, 72.45; H, 5.4; N, 2.8; S, 6.4%).

3:5-Diphenyl-2-(2'-benzoylvinylyl)pyrrole (XVIII; R = Ph).—A solution of 2:4-diphenylpyrrole (1 g.) and phenyl ethynyl ketone (0.6 g.) in methyl alcohol (40 c.c.) was refluxed for one minute and allowed to stand overnight. 3:5-Diphenyl-2-(2'-benzoylvinylyl)pyrrole (1.4 g.) crystallised in orange-red prisms, which were recrystallised from methyl alcohol. The pure adduct, m. p. 212°, dissolved in concentrated sulphuric acid to a red solution (Found: C, 85.9; H, 5.45; N, 3.85. $C_{22}H_{18}ON$ requires C, 85.9; H, 5.45; N, 4.0%).

Bis-2-(3:5-diphenylpyrrole)- α -phenyltrimethincyanine Bromide (XIX; R = Ph).—The foregoing compound (1.75 g.) and 2:4-diphenylpyrrole (1.1 g.) in acetic acid (3 c.c.) were treated with a 50% solution of hydrobromic acid in acetic acid (0.8 c.c.). An immediate deep violet coloration was produced and the mixture was warmed on the steam-bath for 40 minutes. After cooling, the adduct was separated, washed with methyl alcohol, and crystallised from chloroform to give bis-2-(3:5-diphenylpyrrole)- α -phenyltrimethincyanine bromide as violet prisms with a golden lustre, m. p. 245—246° (Cook and Majer, *loc. cit.*, give m. p. 245°).

3:5-Diphenyl-2-(but-1'-en-3'-onyl)pyrrole (XVIII; R = Me).—Prepared similarly to the phenyl analogue from 2:4-diphenylpyrrole (1 g.) and methyl ethynyl ketone (0.3 g.) in methyl alcohol (40 c.c.), and crystallised from methyl alcohol, 3:5-diphenyl-2-(but-1'-en-3'-onyl)pyrrole (1.1 g.) formed orange prisms, m. p. 207°, which dissolved in concentrated sulphuric acid to a deep orange solution (Found: C, 83.3; H, 5.85; N, 5.1. $C_{20}H_{18}ON$ requires C, 83.6; H, 5.9; N, 4.9%).

Bis-2-(3:5-diphenylpyrrole)- α -methyltrimethincyanine Bromide (XIX; R = Me).—The pyrrole (XVIII; R = Me) (0.3 g.) and 2:4-diphenylpyrrole (0.2 g.) in ethyl acetate (2 c.c.) were treated with a 50% solution of hydrobromic acid in acetic acid (0.3 c.c.), and the mixture heated on the steam-bath for one hour. The green dye was separated, and crystallised from ethyl acetate-ether, forming green plates, m. p. 224° (Cook and Majer, *loc. cit.*, give m. p. 225°).

1-Phenyl-3-methyl-4-(but-1'-en-3'-onyl)-5-pyrazolone (XX).—1-Phenyl-3-methyl-5-pyrazolone (1 g.) and methyl ethynyl ketone (0.4 g.) in methyl alcohol (10 c.c.) were refluxed for one minute, and the red solution kept at room temperature for 2 days. 1-Phenyl-3-methyl-4-(but-1'-en-3'-onyl)-5-pyrazolone was separated and crystallised from methyl alcohol, forming yellow hair-like crystals, m. p. 181° (Gaspar, *loc. cit.*, gives m. p. 177°) (Found: C, 69.7; H, 5.3. Calc. for $C_{14}H_{14}O_2N_2$: C, 69.4; H, 5.8%).

2-Methyl-3-(2'-benzoylvinylyl)indole (XXI).—2-Methylindole (1 g.) and phenyl ethynyl ketone (1 g.) were dissolved in methyl alcohol (5 c.c.) and allowed to stand overnight. 2-Methyl-3-(2'-benzoylvinylyl)-indole was separated, and crystallised from methyl alcohol in orange prisms, m. p. 183—184° (Found: C, 82.5; H, 5.6; N, 5.5. $C_{18}H_{14}ON$ requires C, 82.8; H, 5.75; N, 5.35%).

3-Benzoyl-6-phenylpyridine and s-Tribenzoylbenzene.—Phenyl ethynyl ketone (1 g.) in acetic acid (1 c.c.) was treated with a cold saturated solution of ammonium acetate (0.8 g.) in acetic acid, and the mixture kept at room temperature for 3 days. The precipitated solid was thoroughly extracted with 2*N*-hydrochloric acid (3 \times 10 c.c.), and the acid extract basified to Clayton-yellow, whereupon crude 5-benzoyl-2-phenylpyridine was obtained. Repeated crystallisation from alcohol with carbon clarification gave the base as almost colourless plates (0.2 g.), m. p. 86—87° (Bowden and Jones, *J.*, 1946, 953, give m. p. 84—85°). The residue from the acid extract was crystallised from alcohol, and s-tribenzoylbenzene was obtained as colourless needles (0.3 g.), m. p. 119° (Claisen, *Annalen*, 1894, 281, 307, gives m. p. 118—119°).

The author is indebted to Mr. J. D. Rose for his interest in this work.

[Received, February 8th, 1947.]

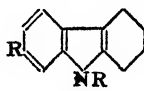

325. *The Friedel-Crafts Reaction with 1-Acyl-2:3-dimethylindoles.*

By W. J. GAUDION, W. H. HOOK, and S. G. P. PLANT.

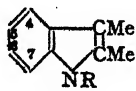

Substances derived from 1-acetyl- and 1-benzoyl-2:3-dimethylindole by the Friedel-Crafts reaction have been hydrolysed to a compound which has been proved to be 6-acetyl-2:3-dimethylindole. 2:3-Dimethyl-6-ethylindole has been obtained from it by reduction and subsequent dehydrogenation, as well as from 2-acetamido-1:4-diethylbenzene by the action of potassium *tert*-butoxide. The results are analogous to those previously observed in the carbazole group. Certain reactions of 1:6-diacetyl-2:3-dimethylindole have been studied.

EARLIER work has shown that while disubstitution at the 3- and 6-positions readily takes place when acid chlorides and anhydrides act under the conditions of a Friedel-Crafts reaction on carbazole and its 9-alkyl derivatives, similar treatment of the 9-acylcarbazoles leads to monosubstitution at the 2-position (see, *e.g.*, Plant, Rogers, and Williams, *J.*, 1935, 741;

Mitchell and Plant, *J.*, 1936, 1295). Plant and Rogers (*J.*, 1936, 40) found that 9-acetyl- and 9-benzoyl-tetrahydrocarbazole gave their 7-acetyl and 7-benzoyl derivatives (I; R = Ac or Bz) under similar conditions, and it seemed probable that the 6-position would be that normally

(I.)

(II.)

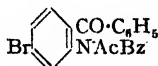

(III.)

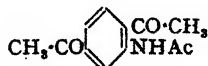

taken by the substituent in Friedel-Crafts reactions with simple indoles such as the 1-acyl-2:3-dimethylindoles (II; R = Acyl). In order to investigate this, 1-acetyl-2:3-dimethylindole was treated with acetyl bromide (or chloride) and aluminium chloride, and a diacetyl-2:3-dimethylindole, m. p. 116°, was obtained. A small quantity of a triacetyl-2:3-dimethylindole was formed at the same time, and this was also prepared by a further application of the Friedel-Crafts reaction to the diacetyl compound, m. p. 116°. 1-Benzoyl-2:3-dimethylindole was converted under similar conditions into an acetyl derivative, which, on hydrolysis, gave an acetyl-2:3-dimethylindole, m. p. 154°, identical with that obtained by the hydrolysis of the diacetyl compound. That the substance, m. p. 154°, was not 5-acetyl-2:3-dimethylindole was proved by reducing it by the Clemmensen method. The resulting 2:3-dimethylethylindoline, which formed a characteristic phenylcarbamyl derivative, gave, on dehydrogenation, a 2:3-dimethylethylindole, m. p. 74°, different from 2:3-dimethyl-5-ethylindole synthesised from *p*-ethylphenylhydrazine and methyl ethyl ketone. Further investigations into the structure of these products had to be discontinued early in 1940 for the duration of the war. In the meantime Borsche and Groth (*Annalen*, 1941, 549, 238) have treated 1-acetyl-2:3-dimethylindole with acetyl chloride and aluminium chloride and obtained a compound, m. p. 115–116°, which they called 1:6-diacetyl-2:3-dimethylindole. It was hydrolysed to a substance, m. p. 153°, stated to be 6-acetyl-2:3-dimethylindole. No experimental evidence was adduced for the structures, which were assigned on the basis of the work of Plant and others referred to above.

The validity of these assumptions has now been established by the synthesis of 2:3-dimethyl-6-ethylindole from 2-acetamido-1:4-diethylbenzene (III), m. p. 154°, by heating it with potassium *tert*-butoxide under conditions similar to those used by Marion and Ashford (*Canadian J. Res.*, 1945, 23B, 26; see also Tyson, *J. Amer. Chem. Soc.*, 1941, 63, 2024) for the preparation of 2:3-dimethylindole from *o*-acetamidoethylbenzene. The product proved to be identical with the substance, m. p. 74°, obtained by the reactions already mentioned. Voswinkel (*Ber.*, 1889, 22, 315) claims to have prepared 2-acetamido-1:4-diethylbenzene from the corresponding amine, obtained from 2-nitro-1:4-diethylbenzene, but the m. p. is given as 99° and the substance was not analysed. The conditions described in the experimental section for the nitration of *p*-diethylbenzene were found to be more satisfactory than those mentioned by Voswinkel, which led to a considerable quantity of a dinitro-compound, as was evident from the fact that a bisacetamido-1:4-diethylbenzene could be prepared from the basic material obtained by reduction of the product.

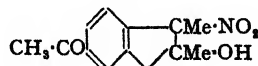

Koelsch (*J. Amer. Chem. Soc.*, 1944, 66, 1983) has found that 6-bromo-1-acetyl-2:3-dimethylindole can be oxidised to 5-bromo-2-benzoyl-*N*-acetylbenzanilide (IV) by chromic acid in acetic acid solution. When 1:6-diacetyl-2:3-dimethylindole was treated in this way,

(IV.)

(V.)

(VI.)

2:5-diacetylacetanilide (V) was isolated, evidently after removal of one of the *N*-acetyl groups from the analogous primary oxidation product. It was also found that *o*-acetamidoacetophenone could be similarly obtained from 1-acetyl-2:3-dimethylindole. Nitration of 1:6-diacetyl-2:3-dimethylindole has given a nitro-derivative together with 3-nitro-2-hydroxy-1:6-diacetyl-2:3-dimethylindoline (VI). The latter, which was colourless, soluble in alkali, and melted with evolution of oxides of nitrogen, had the behaviour characteristic of this type of compound, the formation of which is a well-established feature of the 1-acyl-2:3-dialkylindoles (see, *e.g.*, *J.*, 1933, 955; 1940, 283).

3-Acetylcarbazole can be readily prepared by heating 9-acetylcarbazole with aluminium chloride in nitrobenzene (Plant, Rogers, and Williams, *loc. cit.*). Attempts to obtain 5-acetyl-2:3-dimethylindole similarly from the 1-acetyl compound have given an unsatisfactory

product, from which a little 6-acetyl-2:3-dimethylindole was the only pure material isolated. This behaviour is reminiscent of that observed with 9-acetyltetrahydrocarbazole (Plant and Rogers, *loc. cit.*).

EXPERIMENTAL.

1:6-Diacetyl-2:3-dimethylindole.—Aluminium chloride (25 g.) was added to 1-acetyl-2:3-dimethylindole (9.4 g.) and acetyl bromide (17 g.) in carbon disulphide (120 c.c.), the whole refluxed for 2½ hours, the solvent distilled off, and the residue added to ice-dilute hydrochloric acid. When the product was crystallised from alcohol, 1:6-diacetyl-2:3-dimethylindole (8.5 g.) was obtained in colourless prisms, m. p. 116° (Found: C, 73.2; H, 6.5. Calc. for $C_{14}H_{12}O_2N$: C, 73.4; H, 6.5%). The same substance resulted from the use of a restricted amount (6.4 g.) of acetyl chloride instead of acetyl bromide. When the material obtained by concentrating the alcoholic mother liquors was recrystallised from light petroleum, a triacetyl-2:3-dimethylindole separated in colourless needles, m. p. 117° (Found: C, 76.8; H, 6.3. $C_{14}H_{10}O_3N$ requires C, 76.8; H, 6.3%).

The same triacetyl compound (mixed m. p.) was obtained in good yield when a mixture of 1:6-diacetyl-2:3-dimethylindole (1.15 g.), acetyl chloride (0.5 g.), aluminium chloride (2.5 g.), and carbon disulphide (15 c.c.) was refluxed for 2 hours, and the product crystallised from alcohol.

1-Benzoyl-6-acetyl-2:3-dimethylindole.—When 1-benzoyl-2:3-dimethylindole (5 g.) was treated with acetyl chloride (2.4 g.) and aluminium chloride (8 g.) in carbon disulphide (50 c.c.) as described for the corresponding acetyl compound, and the product crystallised from alcohol, 1-benzoyl-6-acetyl-2:3-dimethylindole was obtained in colourless needles (4 g.), m. p. 117° (Found: C, 78.0; H, 5.9. $C_{15}H_{12}O_2N$ requires C, 78.3; H, 5.8%). After its solution in aqueous-alcoholic potassium hydroxide had been refluxed for 2 hours, the addition of water precipitated 6-acetyl-2:3-dimethylindole. This separated from aqueous alcohol in yellow prisms, m. p. 154° (Found: N, 7.3. Calc. for $C_{13}H_{10}ON$: N, 7.5%), identical (mixed m. p.) with the substance similarly obtained from 1:6-diacetyl-2:3-dimethylindole.

2:3-Dimethyl-6-ethylindole.—After *p*-ethylphenylhydrazine (2.89 g.) and methyl ethyl ketone (1.54 g.) had been warmed for a few minutes on the steam-bath, the resulting hydrazone was taken up in ether, the solution dried (K_2CO_3), and evaporated. The residue was heated with powdered zinc chloride (2 g.) at 180° for 5 minutes, and the product extracted with boiling light petroleum. 2:3-Dimethyl-6-ethylindole separated from the extract in colourless plates, m. p. 62° (Found: C, 82.9; H, 8.9. $C_{12}H_{15}N$ requires C, 83.2; H, 8.7%).

2:3-Dimethyl-6-ethylindole.—(a) 6-Acetyl-2:3-dimethylindole (4.7 g.) and concentrated hydrochloric acid (30 c.c.) were added to amalgamated granulated zinc (50 g.), the mixture shaken, and left overnight. After the addition of more hydrochloric acid (100 c.c. of 28%), the whole was refluxed for 12 hours, made alkaline with concentrated aqueous sodium hydroxide, and steam distilled. When the distillate was extracted with ether, and the extract dried and fractionated, 2:3-dimethyl-6-ethylindole (2.2 g.) was obtained as a colourless oil, b. p. 133°/13 mm. (Found: C, 82.7; H, 10.4. $C_{12}H_{15}N$ requires C, 82.3; H, 9.7%). The base (1 g.) was heated with palladised charcoal (0.25 g.) for 4 hours at 260° in an atmosphere of hydrogen, the product dissolved in acetone, the solution filtered and poured into dilute hydrochloric acid. The precipitated solid was crystallised from aqueous alcohol, from which 2:3-dimethyl-6-ethylindole separated in colourless plates, m. p. 74°, which soon turned brown when left in air (Found: C, 82.7; H, 8.6%).

(b) *p*-Diethylbenzene (20 g.) was gradually added to a well stirred mixture of glacial acetic acid (40 c.c.) and nitric acid (43 c.c., *d* 1.5) at 10–15°, the whole diluted with water, and the product extracted with chloroform. After the extract had been washed with aqueous sodium carbonate, dried, and the solvent removed, 2-nitro-1:4-diethylbenzene (17.4 g.) was obtained, on distillation, as a yellow oil, b. p. 137–140°/12 mm. with some decomposition. The oil (16.5 g.) was heated on the steam-bath for an hour with iron filings (65 g.) and aqueous acetic acid (70 c.c. of 5%), the mixture made alkaline with aqueous sodium carbonate, and the base removed in steam. When extracted from the distillate with ether, dried, and distilled, 2-amino-1:4-diethylbenzene (12.5 g.) was obtained as a colourless oil, b. p. 122°/13 mm. The amine was suspended in three times its volume of water, treated with a slight excess of acetic anhydride, the mixture boiled, and sufficient glacial acetic acid added to effect solution. On cooling, 2-acetamido-1:4-diethylbenzene separated in good yield in colourless needles, m. p. 154° (Found: C, 75.3; H, 8.8; N, 7.5. $C_{14}H_{17}ON$ requires C, 75.4; H, 8.9; N, 7.3%). The acetyl compound (3 g.) was added to a solution of potassium (0.91 g.) in *tert*-butyl alcohol (19 g.), the excess of the alcohol distilled off, and the residue heated at 350–360° for 20 minutes in an atmosphere of nitrogen. When cold, the mixture was treated with water, and the 2:3-dimethyl-6-ethylindole removed in steam. It then separated from aqueous alcohol in colourless plates, m. p. 74°, identical (mixed m. p.) with the substance described above.

After *p*-diethylbenzene (10 g.) had been nitrated by adding it to nitric acid (20 c.c., *d* 1.5) at 0° as described by Voswinkel (*loc. cit.*), and the crude product, without distillation, reduced as described above, the 2-amino-1:4-diethylbenzene was removed in steam and the residual hot aqueous solution filtered. The solid was washed several times with hot water and the united filtrates saturated with salt and extracted with benzene. The extract was dried, acetic anhydride (10 c.c.) added, and the whole refluxed for a few minutes. When cold, the bulky precipitate was collected and recrystallised from cyclohexanone, from which a bisacetamido-1:4-diethylbenzene (2.2 g.) was obtained in pale yellow prisms, m. p. 253–256° (Found: C, 67.6; H, 7.9; N, 11.4. $C_{14}H_{19}O_2N_2$ requires C, 67.7; H, 8.1; N, 11.3%).

1-Phenylcarbonyl-2:3-dimethyl-6-ethylindole.—After a mixture of the indoline with a little less than one molecular proportion of phenyl isocyanate had been heated on the steam-bath for a few minutes, the solid was crystallised from alcohol, and 1-phenylcarbonyl-2:3-dimethyl-6-ethylindole obtained in colourless needles, m. p. 218° (Found: C, 77.1; H, 7.5; N, 9.5. $C_{18}H_{17}ON_2$ requires C, 77.5; H, 7.5; N, 9.5%).

2:5-Diacetylacetanilide.—Chromic anhydride (2.7 g.) in a little water was added to a solution of 1:6-diacetyl-2:3-dimethylindole (3.8 g.) in glacial acetic acid (80 c.c.), the whole left for 2 hours at

room temperature, and then heated for 5 minutes at 70°. After the addition of water (300 c.c.), the filtered solution was extracted with benzene, and the extract shaken with aqueous sodium carbonate, dried (MgSO₄), and evaporated under reduced pressure. When the residue was crystallised from alcohol, 2:6-diacylacetanilide (1.45 g.) was obtained in yellow needles, m. p. 103° (Found: C, 65.9; H, 5.2; N, 6.4. C₁₁H₁₀O₃N requires C, 65.8; H, 5.9; N, 6.4%).

After 1-acetyl-2:3-dimethylindole (3.7 g.) had been similarly oxidised and the product twice crystallised from water, o-acetamidoacetophenone was obtained in pale yellow needles (1.25 g.), m. p. 75° (Found: C, 67.7; H, 6.1; N, 8.3. Calc. for C₁₀H₁₁O₃N: C, 67.8; H, 6.2; N, 7.9%).

Nitration of 1:6-Diacetyl-2:3-dimethylindole.—Nitric acid (0.3 c.c., d 1.5) was added dropwise to a solution of 1:6-diacetyl-2:3-dimethylindole (1 g.) in glacial acetic acid (3 c.c.) at 80°. On cooling, a nitro-derivative (0.2 g.) slowly separated, and, after recrystallisation from acetic acid, it was obtained in practically colourless needles, m. p. 185° (Found: C, 60.9; H, 5.0; N, 10.6. C₁₄H₁₄O₄N₂ requires C, 61.3; H, 5.1; N, 10.2%). When the mother liquor was concentrated under reduced pressure, a small amount of 3-nitro-2-hydroxy-1:6-diacetyl-2:3-dimethylindoline separated. On recrystallisation from acetic acid it was isolated in colourless prisms, m. p. 125° (decomp.) (Found: N, 9.8. C₁₄H₁₄O₄N₂ requires N, 9.6%).

Action of Aluminium Chloride on 1-Acetyl-2:3-dimethylindole.—After a solution of the acetyl compound (2 g.) and aluminium chloride (2 g.) in nitrobenzene (20 c.c.) had been heated at 115° for 20 minutes, water was added, and the nitrobenzene removed in steam. When the residual sticky solid was dried, distilled under reduced pressure, and twice recrystallised from alcohol, a small amount of 6-acetyl-2:3-dimethylindole was obtained in yellow prisms, m. p. 151–153°, and identified by mixed m. p.

326. *The Stereochemistry of Organic Derivatives of Phosphorus. Part II. The Synthesis of 2:2-Disubstituted 1:2:3:4-Tetrahydroisophospholinium Salts and the Optical Resolution of 2-Phenyl-2-p-hydroxyphenyl-1:2:3:4-tetrahydroisophospholinium Bromide.*

By FREDERICK G. HOLLIMAN and FREDERICK G. MANN.

Numerous attempts to synthesise the tetrahydroisophospholine ring system by the use of o-2-bromoethylbenzyl bromide (cf. Holliman and Mann, *J.*, 1942, 737; 1943, 547, 550) and by other methods having failed, a general synthesis for 2:2-diaryl-1:2:3:4-tetrahydroisophospholinium salts has been developed and applied to the preparation of 2-phenyl-2-p-bromophenyl- and 2-phenyl-2-p-hydroxyphenyl-1:2:3:4-tetrahydroisophospholinium bromides. Whilst the former salt resisted all attempts at resolution into optically active forms, the dextrorotatory form of the latter, having $[M]_D + 32.9^\circ$, was isolated on one occasion: the corresponding levorotatory form could not be obtained nor could the successful resolution be repeated, these failures being attributed to the formation of partial racemates. This represents the first recorded example of an asymmetric quaternary phosphonium salt showing optical activity.

THE ready resolution of 2-phenyl-2-p-chlorophenacyl-1:2:3:4-tetrahydroisarsinolinium bromide (I) and the high optical stability of the isomers obtained (Holliman and Mann, *J.*, 1943, 550), in contrast to the fleeting rotation displayed by other optically active arsonium salts (Burrows and Turner, *J.*, 1921, 19, 426; Kamai, *Ber.*, 1933, 66, 1779; *J. Gen. Chem. Russia*, 1934, 4, 184), was attributed to the great chemical stability of the above heterocyclic ring system and the consequent inability for racemisation to proceed by a dissociation equilibrium:

It was pointed out that such an equilibrium was almost certainly responsible for the many previous unsuccessful attempts to resolve quaternary arsonium salts, particularly since these salts always contained at least one alkyl group which would lend itself very readily to the above dissociation.

It would seem that similar arguments could be put forward to explain the lack of success attending some of the many attempts to resolve quaternary phosphonium salts [e.g., Pope and Gibson (*J.*, 1912, 101, 735) failed to resolve phenyl-p-tolylbenzylmethylphosphonium iodide, Wedekind (*Ber.*, 1912, 45, 2933) failed with phenyl-p-tolylmethylethylphosphonium iodide, and Meisenheimer *et al.* (*Annalen*, 1926, 449, 213) had no success with phenylbenzylmethylethylphosphonium iodide] but in the majority of cases, investigators have been handicapped by the inherent difficulties involved in the crystallisation of phosphonium salts with optically active anions (Michaelis, *Annalen*, 1901, 315, 43; Pope and Gibson, *loc. cit.*; Wedekind, *loc. cit.*; Radcliffe and Brindley, *J. Soc. Chem. Ind.*, 1923, 42, 64; Kamai, *J. Gen.*

Chem. Russia, 1932, 2, 526; Davies and Mann, *J.*, 1944, 276). On the other hand, evidence has been produced that phosphonium salts do not undergo dissociation in solution as postulated above (Wedekind, *loc. cit.*, but cf. Davies and Lewis, *J.*, 1934, 1600) and it may be that when crystalline salts have been obtained, they have been in the form of partial racemates: if such a form is less soluble than either of the two diastereoisomerides, resolution is obviously impossible.

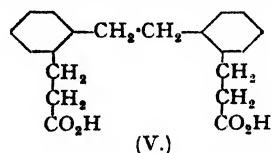

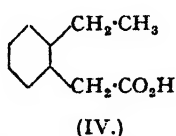

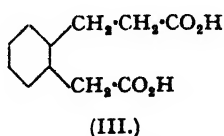

As a sequel to the successful resolution of the asymmetric arsonium salt (I) it seemed highly probable that, could the analogous phosphorus compound, 2-phenyl-2-*p*-chlorophenacyl-1:2:3:4-tetrahydroisophospholinium bromide (II), be prepared it would be possible to

resolve it into optically active forms: crystallisation difficulties would be overcome since derivatives of (II) would probably be isomorphous with corresponding derivatives of (I), and in addition a dissociation equilibrium would be unlikely to operate.

The application of similar methods for the synthesis of (II) to those employed for the arsenic analogue (I) gave only poor yields in the first stage (*i.e.*, the Michaelis reaction between *o*-2-bromoethylbenzyl bromide, phenyldichlorophosphine and sodium in an ethereal medium with ethyl acetate as a catalyst to give 2-phenyl-1:2:3:4-tetrahydroisophospholine) as has already been reported (Holliman and Mann, *J.*, 1943, 548) and subsequent attempts to improve the yields by varying the solvent, the proportions of the reactants, and the catalyst all met with no success. The reasons for this failure are not difficult to formulate. The Michaelis reaction is known to proceed much more slowly in the case of phosphorus halides than with those of arsenic: for example, bromobenzene, phosphorus trichloride, and sodium in ether require 48 hours' refluxing to obtain a small yield of triphenylphosphine (Michaelis and Gleichman, *Ber.*, 1882, 15, 801) whilst the analogous reaction with arsenic trichloride proceeds vigorously and is complete in a short time to give high yields of triphenylarsine (Michaelis and Reese, *ibid.*, p. 2876). On the other hand, the rate of quaternary phosphonium salt formation by the interaction of tertiary phosphines with alkyl halides is many times more rapid than the similar formation of quaternary arsonium salts: the reaction between phenyldiethylphosphine and ethyl iodide in acetone is more than 90% complete after 60 hours, whilst the corresponding reaction with the arsenic analogue is only 20% complete in the same time (Davies and Lewis, *loc. cit.*). Hence, as fast as the phenylisophospholine is formed, phosphonium salt formation takes place with the unreacted *o*-2-bromoethylbenzyl bromide. In another investigation, it was apparent that *p*-tolylidichloroarsine took part in the Michaelis reaction with greater ease than did phenyldichloroarsine. Consequently, the reaction of *p*-tolylidichlorophosphine with *o*-2-bromoethylbenzyl bromide and sodium was investigated in the hope that the rate of phosphine formation would be markedly increased relative to the rate of subsequent phosphonium salt formation, and that a possibly small but workable yield of 2-*p*-tolyl-1:2:3:4-tetrahydroisophospholine would result. This, however, proved not to be the case, only a small amount of distillate being obtained. The latter did in fact appear to be the required tertiary phosphine since it reacted in benzene solution with *p*-chlorophenacyl bromide to give the crystalline 2-*p*-tolyl-2-*p*-chlorophenacyl-1:2:3:4-tetrahydroisophospholinium bromide (as II), but the yield was too small to justify prolonged experimental work to accumulate sufficient of the phosphonium salt for resolution purposes.

Attention was now directed to a fuller investigation of the conditions under which *o*-2-bromoethylbenzyl bromide would react with magnesium with a view to the use of the di-Grignard reagent from the dibromide for the synthesis of tetrahydroisophosphinolines. Employing the entrainment method, *i.e.*, admixture of the dibromide with ethyl bromide, it was found that reaction with magnesium would take place. Treatment of the reagent so produced

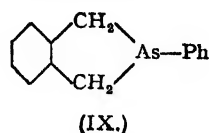

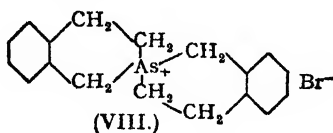

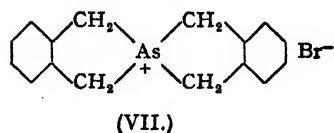

with carbon dioxide was used as a diagnostic method for the presence of the required Grignard reagent, it being anticipated that β -*o*-carboxymethylphenylpropionic acid (III) would be

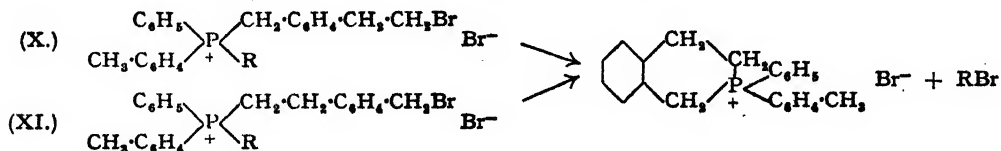

obtained. However, the alkali-soluble fraction of the reaction product was a mixture from which were isolated *o*-ethylphenylacetic acid (IV) and a compound, $C_{20}H_{22}O_4$, which was probably either (V) or an isomer thereof. The isolation of these two acids would indicate that the di-Grignard reagent had, in fact, been produced; it then underwent coupling reactions and subsequent reaction with carbon dioxide to give acids of the type (V), or only partly reacted with carbon dioxide to give (IV). Obviously, it is only the yield of (III) and (IV) which is the measure of the degree to which this type of reaction could be employed in the synthesis of tetrahydroisophosphinolines, and the low yield actually obtained caused this method to be abandoned in favour of other syntheses, which, at the time, showed greater promise of success.

The impracticability of synthesising the phenylisophosphinoline necessary for the preparation of the phosphorus analogue of our arsonium salt led us to consider possible routes for the synthesis of a somewhat different type of phosphinolinium salt. The stability of this type of heterocyclic system has already been discussed and it has been pointed out (Davies and Mann, *loc. cit.*) that a quaternary phosphonium salt with four *aryl* groups attached to the phosphorus atom would not be susceptible to a dissociation equilibrium of the type postulated above. A 2:2-diaryl-1:2:3:4-tetrahydroisophospholinium salt of type (VI) would combine both these features and would probably be resolvable provided difficulties of crystallisation could be overcome: it was of course realised that such a pronounced change in constitution from that of our arsonolinium salt would no longer offer the possibility of isomorphism, and the absence of the *p*-chlorophenacyl group, to which we have ascribed the high rotation characteristic of that salt and similar salts with sulphur, selenium, or tellurium as the hetero-atom (Holliman and Mann, *J.*, 1945, 37), might lead to a very pronounced decrease in any optical activity which might be observed.

The pyrolysis of quaternary arsonium salts carrying a methyl group leads to the elimination of that group as methyl halide and the formation of a tertiary arsine. With quaternary arsonium salts of a suitable type this reaction may be employed for the synthesis of heterocyclic systems. For example, Lyon and Mann (*J.*, 1945, 30) have used this reaction for the preparation of *As*-spiro-bisisoarsindolinium bromide (VII), Holliman and Mann (*J.*, 1945, 45) have analogously prepared the spirocyclic arsonium salt (VIII), and Lyon, Mann, and Cookson (this vol., p. 662) have synthesised the simpler heterocyclic system of 2-phenylisoarsindoline (IX).

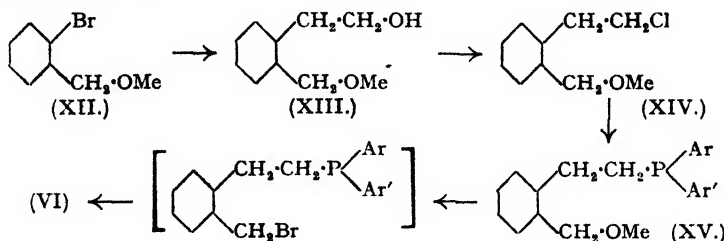

The application of this method to the synthesis of 2:2-diaryl-1:2:3:4-tetrahydroisophospholinium salts was therefore investigated. Meisenheimer *et al.* (*loc. cit.*) have shown that the ease with which radicals are split from quaternary phosphonium chlorides is in the order $Et > CH_3Ph > Me > Pr > isoamyl > Ph$. Accordingly, phenyl-*p*-tolylethylphosphine was brought into reaction with an equimolecular proportion of *o*-2-bromoethylbenzyl bromide to give a crystalline, homogeneous quaternary phosphonium salt which was almost certainly phenyl-*p*-tolyl-*o*-(2-bromoethyl)benzylethylphosphonium bromide (X, $R = Et$) and not the isomeric

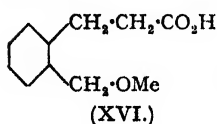

salt (XI, $R = Et$). However, when this salt was heated under varying conditions, although extensive decomposition took place, none of the desired cyclised product could be isolated and examination of the volatile products evolved during the decomposition failed to show any ethyl bromide. Similar experiments involving the use of the corresponding methyl compounds (X or XI; $R = Me$) also proved fruitless.

It was felt that the readiness with which tertiary phosphines form quaternary salts with alkyl halides could be advantageously employed for closing the tetrahydroisophosphinoline

ring, and ultimately the following general synthesis of 2:2-diaryl-tetrahydroisophospholinium salts was successfully developed.

The compounds (XII) and (XIII) are, of course, analogous to intermediates in the synthesis of *o*-2-bromoethylbenzyl bromide and were prepared by similar methods: *o*-bromobenzyl bromide when treated with a methyl-alcoholic solution of sodium methoxide gave *o*-bromobenzyl methyl ether (XII) which was in turn converted into the Grignard reagent by the entrainment method and then treated with ethylene oxide to give *o*-2-hydroxyethylbenzyl methyl ether (XIII). Replacement of the hydroxyl group of the alcohol (XIII) was first attempted using phosphorus tribromide, but fission of the ether grouping also occurred and *o*-2-bromoethylbenzyl bromide together with isochroman were the main products of the reaction; by the use of the theoretical quantity of thionyl chloride in the presence of one molecular proportion of pyridine good yields of *o*-2-chloroethylbenzyl methyl ether (XIV) were obtained. Conversion of the chloro-compound into the Grignard reagent followed by treatment with a diarylchlorophosphine then gave the

tertiary phosphine (XV). At first, difficulty was experienced in the formation of the Grignard reagent from (XIV), and again the carbon dioxide method was employed so that the yields of β -*o*-methoxymethylphenyl-propionic acid (XVI) isolated gave an indication of the yields of the Grignard reagent under various conditions. By far the best reproducible yields were obtained by running a mixture of the chloro-compound with

$\frac{1}{2}$ mol. of ethyl bromide in ethereal solution on to ordinary magnesium turnings, although the chloro-compound alone would react with activated magnesium.

When the tertiary phosphine (XV) was heated in a mixture of constant-boiling hydrobromic acid and glacial acetic acid, the three stages, *i.e.*, cleavage of the ether grouping, esterification, and ring closure, necessary to complete the synthesis were accomplished in one operation, giving good yields of the isophospholinium salt (VI): a stream of hydrogen bromide mixed with hydrogen was passed through the solution in order that the hydrogen bromide concentration should be maintained and that the methyl bromide produced in the ether cleavage should be removed as fast as it was formed, thus being prevented from reacting with the tertiary phosphine.

The above synthesis was first employed to prepare 2-phenyl-2-*p*-bromophenyl-1:2:3:4-tetrahydroisophospholinium bromide (VI; Ar = Ph, Ar' = *p*-C₆H₄Br) as a crystalline solid which with an aqueous solution of sodium picrate gave the phospholinium picrate. The intermediate phenyl-*p*-bromophenyl-2-(*o*-methoxymethylphenyl)ethylphosphine (XV; Ar = Ph, Ar' = *p*-C₆H₄Br) was obtained as a colourless, viscous, high-boiling liquid which readily reacted with methyl iodide in ethereal solution to give the crystalline methiodide.

For resolution, the bromide was converted by the usual method into the *d*-bromocamphorsulphonate, the *d*-hydrogen tartrate and the *l*-*N*-1-phenylethylphthalamate,* but all these salts were non-crystalline glasses or syrups: the *d*-camphorsulphonate was obtained crystalline but repeated recrystallisation from alcoholic ether failed to produce any evidence that a mixture of diastereoisomerides was present.

The introduction of a hydroxyl group into one of the two aryl groups was considered to be a likely means of increasing the probability that crystalline phosphonium salts with optically active anions would be obtained: should these derivatives not prove suitable, benzylation of the hydroxyl group or some similar procedure might again increase the crystallisability. Accordingly, employing phenyl-*p*-anisylchlorophosphine in place of the phenyl-*p*-bromophenyl-chlorophosphine previously used, we were able to prepare phenyl-*p*-anisyl-2-(*o*-methoxymethylphenyl)ethylphosphine (XV; Ar = Ph, Ar' = *p*-C₆H₄OMe), again characterised by the formation of the methiodide. The demethylation-ring closure procedure also resulted in the demethylation

* For the preparation of the phthamic acid and its conversion into the silver salt, see Mann and Watson, this vol., p. 510.

of the *p*-anisyl group and the crystalline 2-phenyl-2-*p*-hydroxyphenyl-1:2:3:4-tetrahydroisophosphinolinium bromide (VI; Ar = Ph, Ar' = *p*-C₆H₄·OH) was thus readily obtained in high yield. That this product did in fact contain a free hydroxyl group was shown by its conversion into the *acetyl* derivative.

The effect of the introduction of the hydroxyl group was soon apparent, as the *d*-bromocamphorsulphonate prepared from the bromide was readily obtained in the crystalline state. Again, however, repeated recrystallisation from a variety of solvents failed to produce any indication that resolution was proceeding.

Similarly, the *d*-camphorsulphonate, originally obtained as a glass, readily crystallised from an acetone solution, and then had m. p. 153—158° and $[M]_D + 102^\circ$ in alcoholic solution. Slow recrystallisation from ethyl acetate—ethyl alcohol gave a first crop having m. p. 171—172.5° and $[M]_D + 110^\circ$, whilst a second and a third crop had respectively, m. p. 153—157° and 142—151°, $[M]_D + 104^\circ$ and $+ 98.4^\circ$. That the first crop was virtually the optically pure *d*-phosphonium *d*-camphorsulphonate was evident since three more recrystallisations of this crop raised the m. p. to a constant value of 174—175° and the $[M]_D$ to $+ 113.5^\circ$.

An alcoholic solution of the optically pure camphorsulphonate, treated at 0° with an alcoholic solution of calcium bromide, furnished the *d*-phosphinolinium bromide, m. p. 268—270°, with $[M]_D + 32.9^\circ$ in aqueous alcoholic solution: it is noteworthy that the *dl*-phosphinolinium bromide had m. p. 287—287.5° and that the optically active salt was considerably more soluble than the racemic compound. A curious solvent effect was observed in methyl alcohol, solutions of the bromide in this solvent having very low activity: this was not due to racemisation, for the bromide recovered from such solutions had the normal activity when again dissolved in aqueous ethyl alcohol. The optical stability and purity of the active bromide is shown by the fact that recrystallisation from boiling ethyl alcohol failed to affect the rotatory power.

The following values for the rotatory dispersion in the visible spectrum were obtained for a 1.029% solution of the *d*-bromide in aqueous-alcoholic solution. The calculated rotations are obtained from the equation $\alpha = k/(\lambda^2 - \lambda_0^2)$, where $k = 0.0885$ and $\lambda_0^2 = 0.0948$, $\lambda_0 = 3078 \text{ \AA}$.

Source of light.	Li.	Na.	Hg.	Hg.	Cu.	Zn.	Hg.
$\lambda, \text{ \AA}.$	6104	5893	5780	5461	5219	4810.5	4358
$\alpha, \text{ obs.}$	$+0.31^\circ$	0.36°	0.37°	0.435°	0.48°	0.64°	0.93°
$[M]_D$	$+30.05^\circ$	34.9°	35.9°	42.2°	46.5°	62.0°	90.1°
$\alpha, \text{ calc.}$	$+0.32^\circ$	0.35°	0.37°	0.435°	0.50°	0.65°	0.93°
$\alpha, \text{ obs.} - \alpha, \text{ calc.}$	-0.01°	$+0.01^\circ$	0.00°	0.00°	-0.02°	-0.01°	0.00°

The close agreement between the observed and the calculated values indicates that the bromide probably possesses simple dispersion, although readings for a much greater number of wave-lengths would have to be obtained to establish this beyond doubt.

In order to obtain the *l*-bromide, the phosphinolinium bromide was recovered from the second and third fractions of the *d*-camphorsulphonate and then converted into the *l*-camphorsulphonate. This salt, like its isomer, was initially obtained as a glass which was crystallised from an acetone solution and then had m. p. 152—157°. When recrystallisation of this salt from ethyl acetate—ethyl alcohol was attempted, the hot solution rapidly began to deposit crystalline material and a much greater proportion of alcohol than was used in the case of the *d*-camphorsulphonate had to be employed before solution was again obtained. In this case, on cooling, practically the whole of the salt was recovered with m. p. 170—172° and $[M]_D - 102^\circ$: further recrystallisation failed to change either the m. p. or the rotatory power. The salt was much less soluble than had been anticipated for the *l*-phosphinolinium *l*-camphorsulphonate and conversion into the phosphinolinium bromide gave only an optically inactive product, m. p. 286—288°: it therefore became apparent that the *l*-camphorsulphonate was now crystallising as a partial racemate. Numerous attempts to re-obtain the low-melting form were of no avail: the less soluble, high-melting form was always obtained in the presence of nuclei, whilst, if steps were taken to ensure that nuclei were excluded, solutions remained supersaturated indefinitely. Similarly, further preparations of the *d*-camphorsulphonate always gave a product, m. p. 170—172°, which, by treatment with calcium bromide, furnished the optically inactive bromide. Attempts to extend the resolution were therefore abandoned.

It is noteworthy that the above 2-phenyl-2-*p*-hydroxyphenyl-1:2:3:4-tetrahydroisophosphinolinium bromide is the first quaternary phosphonium salt to be resolved into optically active forms. The only other types of organic phosphorus derivatives (*i.e.*, derivatives containing C—P links) to be obtained in optically active forms are the tertiary phosphine oxides, such as phenylbenzylmethylphosphine oxide, resolved by Meisenheimer *et al.* (*Ber.*, 1911, 44,

356; *Annalen*, 1926, **440**, 224), and the tertiary phosphine sulphide, phenyl-*p*-carboxymethoxyphenyl-*n*-butylphosphine sulphide, resolved by Davies and Mann (*loc. cit.*).

EXPERIMENTAL.

(All rotations were taken by use of a 4-dm. tube. M. p.s are uncorrected.)

2-*p*-Tolyl-2-*p*-chlorophenacyl-1:2:3:4-tetrahydroisophospholinium Bromide (as II).—*o*-2-Bromoethylbenzyl bromide (29 g.) and *p*-tolylidichlorophosphine (19.3 g., 1 mol.) in absolute ether (350 c.c.) were treated with sodium wire (18 g., 8 atoms), and the mixture refluxed on the water-bath in a stream of dry nitrogen for 4 hours. After this time no apparent change had taken place and ethyl acetate (2.5 c.c.) was added to catalyse the reaction. After a further 4 hours' refluxing, ethyl acetate (2.5 c.c.) was again added and the refluxing continued for 11 hours, by which time the sodium wire had broken up and a heavy white precipitate had collected. The mixture was filtered and the ether removed by distillation in an apparatus similar to that described for 2-phenyl-1:2:3:4-tetrahydroisarsinoline (Holliman and Mann, *loc. cit.*). The residual oil was distilled under reduced pressure: after a preliminary, low-boiling fraction, a small amount of distillate was collected at 150–180°/0.1 mm. The latter possessed a pronounced phosphine-like odour and reacted with methyl iodide to give an oily product. When dissolved in benzene and treated with *p*-chlorophenacyl bromide, no precipitation took place, but evaporation to dryness, dissolution in alcohol, and subsequent addition of ether caused the precipitation of a white solid which was purified by precipitation with ether from an alcoholic solution. The phosphonium bromide then had m. p. 227–230° (Found: C, 60.65; H, 5.1; Cl, 7.7; Br, 17.5. $C_{24}H_{23}OClBrP$ requires C, 60.8; H, 4.8; Cl, 7.5; Br, 16.9%. The Cl and Br were calculated from a total halogen estimation on the assumption that they were present in equi-atomic proportions).

From the low-boiling distillate, unchanged *p*-tolylidichlorophosphine, b. p. 70–80°/0.25 mm., was isolated, together with a fraction at 30°/0.5 mm. The latter boiled at 162° at atmospheric pressure and proved to be *o*-ethyltoluene (Found: C, 89.6; H, 9.6. Calc. for C_9H_{12} : C, 90.0; H, 10.0%).

Reaction of *o*-2-Bromoethylbenzyl Bromide with Magnesium.—Preliminary experiments showed that the dibromide would not react with magnesium under the usual conditions of the Grignard reaction. The dibromide (13.9 g.) and ethyl bromide (5.45 g., 1 mol.) were dissolved in dry ether (60 c.c.), and a portion (5 c.c.) of this solution was added to magnesium turnings (3.6 g., 3 atoms) under ether (20 c.c.). After the addition of a crystal of iodine reaction soon set in and the rest of the bromide solution was added so that the ether was kept gently boiling without external chilling. When the whole of the solution had been added, the mixture was refluxed for 6 hours in an atmosphere of nitrogen, after which time only a small amount of magnesium remained. The cooled mixture was poured, in small portions, on powdered solid carbon dioxide (100 g.) covered with dry ether (100 c.c.). After being set aside overnight the product was hydrolysed with dilute sulphuric acid, the ethereal layer separated, and washed with water. The ethereal solution was shaken with 5% sodium hydroxide solution, and the alkaline extract then boiled to remove ether. Acidification of the cooled solution caused precipitation of an oil which crystallised after 2 hours' keeping at 0°. The solid was collected, washed with water, and dried (5.4 g.). Extraction of this solid with boiling petrol (b. p. 80–100°) gave an insoluble residue (1.4 g.), m. p. 168–185°, which after repeated crystallisation from ethyl acetate gave a white, micro-crystalline solid, m. p. 198–200.5° (Found: C, 72.5; H, 6.8. $C_{20}H_{22}O_4$ requires C, 73.5; H, 6.8%). Evaporation of the petrol filtrate left an oil (3.9 g.) which readily crystallised, and when recrystallised twice from water afforded colourless crystals, m. p. 84–85°, raised by another recrystallisation from petrol (b. p. 60–80°) to 85–86°. This compound was evidently *o*-ethylphenylacetic acid (Found: C, 73.0; H, 6.9. Calc. for $C_{10}H_{12}O_2$: C, 73.1; H, 7.4%). Mayer and English (*Annalen*, 1918, **417**, 72) give m. p. 83.5°.

Reaction of *o*-2-Bromoethylbenzyl Bromide with Diarylalkylphosphines.—Phenyl-*p*-tolylethylphosphine (Wedekind, *Ber.*, 1912, **45**, 2935) in ethereal solution was treated with *o*-2-bromoethylbenzyl bromide (1 mol.) also in ethereal solution. The oily precipitate which gradually formed eventually crystallised and was filtered off and cautiously washed with alcohol. The phosphonium bromide (X; R = Et) melted at 146–148° with softening from 143° (Found: C, 56.3; H, 5.3; Br, 31.4. $C_{24}H_{27}Br_2P$ requires C, 56.9; H, 5.3; Br, 31.6%). The thermal decomposition of this salt gave only non-crystalline products from which no crystalline derivative could be prepared.

By a similar method, the phosphonium salt (X; R = Me) was prepared from phenyl-*p*-tolyl-methylphosphine (Radcliffe and Brindley, *loc. cit.*) and the dibromide. It was recrystallised from alcohol-ether and then melted at 185–186° (Found: C, 55.9; H, 5.2; Br, 31.9. $C_{22}H_{25}Br_2P$ requires C, 56.1; H, 5.1; Br, 32.5%). Again thermal decomposition under different conditions always gave glassy products which could neither be crystallised nor converted into crystalline derivatives.

***o*-Bromobenzyl Methyl Ether** (XII).—*o*-Bromobenzyl bromide (200 g.) was cautiously added to a thoroughly chilled solution of sodium (20 g., 1.08 atoms) in methyl alcohol (600 c.c.). The mixture was refluxed on the water-bath for a short time, and the methyl alcohol then distilled off, a current of air being drawn through the mixture to avoid serious bumping. Sodium bromide was dissolved from the residue by the addition of water (500 c.c.), and the insoluble oil extracted with ether. The aqueous layer was again extracted, the combined extracts washed with water, and dried (CaCl₂). After removal of the solvent the residue was fractionated under reduced pressure: yield 145 g. (90%), b. p. 106–107°/16 mm. (Found: C, 47.9; H, 5.5; Br, 40.5. C_8H_9OBr requires C, 47.75; H, 4.5; Br, 39.8%).

***o*-2-Hydroxyethylbenzyl Methyl Ether** (XIII).—The Grignard reagent from *o*-bromobenzyl methyl ether was prepared by running a solution of the bromo-compound (145 g.) and ethyl bromide (26 g., 0.33 mol.) in dry ether (300 c.c.) on to magnesium (35 g., 2.02 atoms) under ether (100 c.c.), the rate of addition being adjusted so that gentle refluxing was maintained whilst the mixture was vigorously stirred. [The magnesium used in this preparation was activated by heating with iodine as described by Holliman and Mann (*loc. cit.*)] When the addition was complete, the mixture was refluxed on the water-bath for 2 hours, then chilled in an ice-salt freezing mixture, and a solution of ethylene oxide (100 g., 3.15 mols.) in ether (600 c.c.) slowly added during 4 hours. The product was set aside overnight

at room temperature, and then chilled in ice-water and hydrolysed cautiously with dilute sulphuric acid (850 c.c., 1 vol. acid : 9 vols. water). The ethereal layer was separated, washed with water, and dried (Na_2SO_4). Removal of the solvent left an oil which was fractionated under reduced pressure yielding the ether (XIII), b. p. 152–154°/14 mm., as the main fraction: yield 64 g. (53%). The product was refracted several times but even so gave an unsatisfactory analysis (Found: C, 74.9; H, 8.2. $\text{C}_{10}\text{H}_{14}\text{O}_2$ requires C, 72.3; H, 8.4%). For characterisation a sample was therefore warmed with phenyl isocyanate to give 2-*o*-methoxymethylphenylethyl *N*-phenylcarbamate as an oil which crystallised on treatment with petrol (b. p. 60–80°). Two recrystallisations from petrol gave colourless crystals, m. p. 64–65° (Found: 72.4; H, 6.5; N, 4.95. $\text{C}_{17}\text{H}_{19}\text{O}_3\text{N}$ requires C, 71.6; H, 6.7; N, 4.9%). As in the synthesis of the corresponding ethyl ether (Holliman and Mann, *loc. cit.*), a forerun of 2-bromoethyl alcohol was also obtained.

***o*-2-Chloroethylbenzyl Methyl Ether (XIV).**—A solution of *o*-2-hydroxyethylbenzyl methyl ether (182 g.) and dry pyridine (87 g., 1 mol.) in chloroform (220 c.c.) was vigorously stirred and chilled in ice-water whilst thionyl chloride (131 g., 1 mol.) was slowly added during 2 hours. The mixture was then transferred to the water-bath and refluxed with vigorous stirring for 2.5 hours; during the initial stages of this process the mixture became cloudy, an oil separated, and sulphur dioxide was evolved, but after 1.5 hours a clear solution had again been produced. After chilling, the chloroform solution was repeatedly washed with water, then with a 1% solution of sodium hydroxide, and finally with water before drying over calcium chloride. The solvent was removed by distillation at atmospheric pressure, and the residue then fractionated under reduced pressure, the fraction, b. p. 131°/14 mm., being collected (146 g., 72%). Upon refractionation the pure *o*-2-chloroethylbenzyl methyl ether was obtained, b. p. 131°/14 mm. (Found: C, 65.0; H, 7.5. $\text{C}_{10}\text{H}_{13}\text{OCl}$ requires C, 65.05; H, 7.0%).

Reaction of *o*-2-Chloroethylbenzyl Methyl Ether with Magnesium.—*o*-2-Chloroethylbenzyl methyl ether (9.2 g.) and ethyl bromide (2.72 g., 0.5 mol.) in dry ether (40 c.c.) were slowly added to magnesium turnings (1.8 g., 1.5 atoms). The reaction was started by gentle warming and then proceeded vigorously whilst the bromide solution was slowly added. After the addition was complete, the mixture was refluxed during 2 hours. The cooled solution was carefully poured on powdered solid carbon dioxide (80 g.) under ether (40 c.c.). The mixture was allowed to attain room temperature, treated with a further quantity of solid carbon dioxide (40 g.), and then set aside during 24 hours. Hydrolysis was performed at 0° with dilute sulphuric acid (100 c.c., 1 vol. acid : 9 vols. water), the ethereal layer separated, washed with water, and extracted with 5% sodium hydroxide solution (100 c.c.). The alkaline filtrate was evaporated to about half bulk, boiled with charcoal, and filtered. Acidification of the chilled filtrate gave a white precipitate which was collected on the filter, washed with water, and dried: yield 5.6 g. (58%) of the practically pure β -*o*-methoxymethylphenylpropionic acid, m. p. 76–78°. Recrystallisation from petrol gave colourless crystals, m. p. 77–78° (Found: C, 68.35; H, 6.95. $\text{C}_{11}\text{H}_{14}\text{O}_3$ requires C, 68.6; H, 7.2%).

Phenyl-*p*-bromophenyl-2-(*o*-methoxymethylphenyl)ethylphosphine (as XV).—The Grignard reagent was prepared from *o*-2-chloroethylbenzyl methyl ether (9.2 g.), ethyl bromide (2.72 g., 0.5 mol.) in ether (40 c.c.), and magnesium turnings (1.8 g., 1.5 atoms) as described above. With a stream of dry nitrogen passing through the apparatus, the mixture was refluxed for 2.5 hours and then chilled in ice-water, whilst, with vigorous stirring, a solution of phenyl-*p*-bromophenylchlorophosphine (16.5 g., 1.1 mols.) (Davies and Mann, *J.*, 1944, 279) in dry ether (60 c.c.) was slowly added during 20 minutes. After refluxing for 3 hours the mixture was set aside overnight with a stream of nitrogen passing through the apparatus to minimise atmospheric oxidation. The mixture was chilled and vigorously stirred whilst being hydrolysed by addition of a solution of ammonium chloride (25 g.) in water (100 c.c.). The nitrogen was now replaced by carbon dioxide and, using a suitable apparatus, the contents of the reaction flask were forced over by gas pressure, through a sintered-glass funnel into a separating funnel from which the air had been displaced by the passage of carbon dioxide. The aqueous layer was run off, and the ethereal layer washed with water and then dried (Na_2SO_4) in an inert atmosphere. The solution, filtered from the drying agent in carbon dioxide, was distilled from the water-bath in a stream of nitrogen. When all the ether had been removed, the residue was fractionated under reduced pressure, the fractions, b. p. 130–160°/0.1–0.2 mm. and 200–230°/0.1–0.2 mm., being collected. The former was a colourless oil, presumably phenyl-*p*-bromophenylethylphosphine (3.1 g., representing 42.5% of the theoretical based on the ethyl bromide used). The high-boiling fraction was a viscous, green, highly refractive oil which upon redistillation gave the pure phenyl-*p*-bromophenyl-2-(*o*-methoxymethylphenyl)ethylphosphine as a viscous, almost colourless oil, b. p. 214–216°/0.1 mm. (Found: C, 63.1; H, 5.5; Br, 18.65. $\text{C}_{22}\text{H}_{22}\text{OBrP}$ requires C, 63.9; H, 5.4; Br, 19.3%; yield, 12 g., 59%).

Methiodide. An ethereal solution of the tertiary phosphine, treated with methyl iodide, rapidly deposited a colourless, sticky semi-solid. The solvent was decanted off, and the gum dissolved in alcohol, ether then being added until a slight cloudiness was produced. On standing for some days, a colourless crystalline precipitate collected; this was filtered off and recrystallised from alcohol, two recrystallisations sufficing to give the pure methiodide as colourless crystals, m. p. 167–168° (Found: C, 49.6; H, 4.8; Br, 14.2; I, 22.5. $\text{C}_{22}\text{H}_{22}\text{OBrIP}$ requires C, 49.7; H, 4.5; Br, 14.4; I, 22.9%). The Br and I were calculated from a total halogen estimation, it being assumed they were present in equi-atomic proportion).

2-Phenyl-2-*p*-bromophenyl-1 : 2 : 3 : 4-tetrahydroisosphospholinium Bromide (as VI).—A stream of anhydrous hydrogen bromide was generated by passing a mixture of bromine vapour with excess of hydrogen through a heated combustion tube and completely freed from free bromine by passage over metallic copper. This gas stream was passed through a solution of phenyl-*p*-bromophenyl-2-(*o*-methoxymethylphenyl)ethylphosphine (6.7 g.) in glacial acetic acid (275 c.c.) and constant-boiling hydrobromic acid (275 c.c.) maintained at 120° in an oil-bath. After 2 hours the acetic acid and hydrobromic acid were distilled off in a vacuum, leaving a brown viscous mass. The latter was dissolved in alcohol (25 c.c.) and again evaporated to dryness under reduced pressure, finally being dried in a vacuum over concentrated sulphuric acid and sodium hydroxide. The gum failed to crystallise and was therefore dissolved in alcohol (100 c.c.), boiled with charcoal, and filtered. The filtrate was concentrated

(40 c.c.), and chilling in ice-water then gave a crystalline precipitate which was collected, washed with alcohol, and dried: m. p. 125—130°. Recrystallisation from ethyl alcoholic ethyl acetate gave colourless crystals of the pure *bromide*, m. p. 137—149° to a viscous cloudy liquid which resolidified and melted at 218—221°, this behaviour persisting in spite of repeated recrystallisation (Found: C, 54.3; H, 4.3; Br, 35.4. $C_{21}H_{19}Br_2P$ requires C, 54.55; H, 4.1; Br, 34.6%). A sample was heated in an oil-bath to the lower m. p. and the heating continued until solidification set in: analysis then indicated that no significant change had taken place (Found: C, 53.6; H, 4.21; Br, 35.7%).

A hot aqueous solution of the phosphonium bromide, treated with an aqueous solution of sodium picrate, gave an emulsion from which a crystalline precipitate was readily obtained. Recrystallisation from alcohol gave the pure *picrate* as glistening, elongated, yellow plates, m. p. 186—187° (Found: C, 53.3; H, 3.4; N, 6.9. $C_{21}H_{19}O_7N_2BrP$ requires C, 53.1; H, 3.4; N, 6.9%).

Conversion of the phosphonium bromide into the *d*-bromocamphorsulphonate, the *d*-hydrogen tartrate, the *l*-*N*-1-phenylethylphthalamate and the *d*-camphorsulphonate was accomplished by the usual method employing the silver salt of the appropriate acid. Of these phosphonium salts only 2-phenyl-2-*p*-bromophenyl-1:2:3:4-tetrahydroisophospholinium *d*-camphorsulphonate was obtained crystalline, m. p. 206—212° (Found: C, 60.1; H, 5.8. $C_{23}H_{24}O_4BrSP$ requires C, 60.6; H, 5.6%). A 0.326% solution in ethyl alcohol had $\alpha_D^{25} = +0.21^\circ$, $[M]_D^{25} = +98.7^\circ$; the m. p. and rotation underwent no significant change upon recrystallisation of the salt from ethyl-alcoholic ether.

Phenyl-p-anisyl-2-(o-methoxymethylphenyl)ethylphosphine (as XV).—This phosphine was prepared in a precisely similar manner to that described for its *p*-bromophenyl analogue described above, phenyl-*p*-anisylchlorophosphine (13.9 g., 1.1 mols.), prepared according to the method of Davies and Mann (*J.*, 1944, 281), being used in place of the phenyl-*p*-bromophenylchlorophosphine. After the small preliminary fraction of phenyl-*p*-anisylethylphosphine, the required *phosphine* was collected at 215—225°/0.1 mm. Refractionation gave the pure phosphine, b. p. 208°/0.05 mm. (Found: C, 76.1; H, 7.2. $C_{22}H_{22}O_2P$ requires C, 75.75; H, 6.9%). yield, 11.8 g., 65%.

In ethereal solution, the phosphine rapidly combined with methyl iodide at room temperature, the *methiodide* being precipitated as a gummy mass. The supernatant ethereal solution was decanted off, and the residue recrystallised from alcohol to give the pure salt as colourless crystals, m. p. 120°—121° (Found: C, 57.1; H, 5.4; I, 25.9. $C_{22}H_{22}O_2IP$ requires C, 56.9; H, 5.6; I, 25.1%).

2-Phenyl-2-*p*-hydroxyphenyl-1:2:3:4-tetrahydroisophospholinium *Bromide* (as VI).—Demethylation, bromination, and ring closure of phenyl-*p*-anisyl-2-(o-methoxymethylphenyl)ethylphosphine was carried out in glacial acetic acid-hydrobromic acid mixture as described in the preparation of the 2-phenyl-2-*p*-bromophenyl analogue; in this case, however, the heating at 120° was for 5 hours. Removal of the glacial acetic and hydrobromic acids under reduced pressure left a crystalline solid which was treated with a small amount of alcohol, filtered off, and washed with ether: m. p. 285—286°. Recrystallisation from methyl alcohol gave colourless crystals, m. p. 287—287.5°, of the pure 2-phenyl-2-*p*-hydroxyphenyl-1:2:3:4-tetrahydroisophospholinium *bromide*, demethylation of the *p*-anisyl group also having taken place (Found: C, 63.4; H, 5.2; Br, 21.0. $C_{21}H_{20}OBrP$ requires C, 63.15; H, 5.1; Br, 20.0%). yield 75%.

A solution of the phosphonium bromide (0.5 g.) in pyridine (8 c.c.) was treated with acetic anhydride (2 c.c.) and the mixture refluxed for 1 hour. The hot solution was filtered from the slight amount of solid which had separated, and the filtrate on cooling gave a crystalline precipitate, which was collected and washed with pyridine followed by ether. The acetyl derivative was much more soluble in alcohol than the original phosphonium bromide, and recrystallisation was accomplished from alcoholic ethyl acetate; the colourless crystals obtained, m. p. 100—103°, were deliquescent when exposed to the air, after 48 hours the m. p. having fallen to ca. 50°. The twice recrystallised 2-phenyl-2-*p*-acetoxyphenyl-1:2:3:4-tetrahydroisophospholinium *bromide* was dried by heating at 80°/1 mm. for 3 hours before analysis (Found: C, 62.2; H, 5.6; Br, 17.2. $C_{23}H_{22}O_4BrP$ requires C, 62.6; H, 5.0; Br, 18.1%).

dl-2-Phenyl-2-*p*-hydroxyphenyl-1:2:3:4-tetrahydroisophospholinium *d*-Bromocamphorsulphonate.—A methyl-alcoholic solution of the bromide was mixed with a similar solution of silver *d*-bromocamphorsulphonate (1 mol.). After boiling for a few minutes, the solution was filtered from the precipitated silver bromide and evaporated to dryness in a vacuum at room temperature. The residual oil was gently warmed with benzene, scratching then readily inducing crystallisation: the m. p. of the unrecrystallised material was 137—147° with softening from 130°, and a 1.015% ethyl-alcoholic solution had $\alpha_D^{17} + 1.94^\circ$, $[M]_D^{17} + 300^\circ$. Two recrystallisations from ethyl alcohol-ethyl acetate raised the m. p. to 145—152° but no change in rotatory power was observed: for a 1.008% ethyl-alcoholic solution, $\alpha_D^{18} + 1.92^\circ$, $[M]_D^{18} + 300^\circ$ (Found: C, 58.7; H, 6.0; Br, 13.6. $C_{21}H_{20}O_4SBP$ requires C, 59.1; H, 5.5; Br, 12.7%).

The salt was next recrystallised repeatedly from isopropyl alcohol. After five such recrystallisations the m. p. was 116—125° in spite of intensive drying at 80°/0.1 mm. Since a 1.030% ethyl-alcoholic solution had $\alpha_D^{19} + 2.00^\circ$, $[M]_D^{19} + 305^\circ$, it was considered that resolution was not proceeding.

Repeated recrystallisation from acetone gave a sample which consistently melted at 135—140° with previous softening. After four recrystallisations the salt in 1.080% ethyl-alcoholic solution had $\alpha_D^{19} + 2.005^\circ$, $[M]_D^{19} + 313^\circ$. The phosphonium bromide was precipitated from an ethyl-alcoholic solution of this sample of the *d*-bromocamphorsulphonate by treatment with an alcoholic solution of sodium bromide at 0°. A methyl-alcoholic solution (0.362%), however, showed no optical activity.

The *d*-camphorsulphonate was prepared by a similar method from silver *d*-camphorsulphonate. The gum remaining after the removal of the solvents was thoroughly freed from methyl alcohol by evacuation at 0.1 mm. for a prolonged period and then dissolved in acetone. After boiling with charcoal the filtered solution was set aside at 0°. After several days practically the whole of the solute had separated as a microcrystalline powder insoluble in hot acetone. This salt was apparently the dl-phosphonium *d*-camphorsulphonate, m. p. 153—158° (Found: C, 67.0; H, 6.3; S, 5.8. $C_{21}H_{20}O_4SP$ requires C, 67.6; H, 6.4; S, 5.8%). 26 G. of the phosphonium bromide gave 27 g. (representing 75% of the theoretical) of this salt after the above process of isolation, and a 0.991% ethyl-alcoholic solution had $\alpha_D^{19} + 0.74^\circ$, $[M]_D^{19} + 102^\circ$. It was far too soluble in methyl, ethyl, or *n*-propyl alcohol for

recrystallisation, and the use of *sec.*-butyl alcohol failed to change either the m. p. or the rotatory power. The salt (25 g.) was boiled with ethyl acetate (150 c.c.), in which it was insoluble, and alcohol carefully added until complete solution was obtained (41.5 c.c. required): after boiling with charcoal and filtering, the solution was set aside for a few days, whereupon clusters of needles began to separate. Crystallisation was allowed to proceed at 2° for three days, and the salt was then collected and washed, first with ethyl acetate-ethyl alcohol (4:1) and then with ethyl acetate: 6.4 g. of colourless needles, m. p. 171–172.5°, were obtained, and a 0.985% solution in alcohol had $\alpha_D^{25} + 0.79^\circ$, $[M]_D^{25} + 110^\circ$. The mother-liquor upon dilution with ethyl acetate (50 c.c.) gave a second crop (5.3 g.), m. p. 153–157°, a 0.990% alcoholic solution having $\alpha_D^{25} + 0.75$, $[M]_D^{25} + 104^\circ$. Evaporation to dryness under reduced pressure gave a third fraction (12 g.), m. p. 142–151°, $\alpha_D^{25} + 0.71^\circ$, $[M]_D^{25} + 98.4^\circ$ for a 0.993% alcoholic solution.

Three more recrystallisations of the first crop from ethyl acetate-ethyl alcohol raised the m. p. of the salt to 174–175°, the optical constants then being $\alpha_D^{25} + 0.81^\circ$, $[M]_D^{25} + 113.5^\circ$ for a 0.983% alcoholic solution. Further treatment failed to alter these values and the salt was evidently the optically pure *d*-phosphonium *d*-camphorsulphonate (Found: C, 68.0; H, 6.46%).

d-2-Phenyl-2-*p*-hydroxyphenyl-1:2:3:4-tetrahydroisosphosphinolinium Bromide.—The *d*-phosphonium *d*-camphorsulphonate (2.2 g.) was dissolved in alcohol (20 c.c.), and the solution cooled to 0° whilst a similarly chilled solution of calcium bromide (5 g.) in alcohol (10 c.c.) was rapidly added. Stirring and scratching caused precipitation of the crystalline bromide, which was collected, and washed with two portions of 5 c.c. and three of 2.5 c.c. of alcohol. 1.5 G. (94%) of the pure bromide were obtained, m. p. 268–270° with softening from 263° (Found: C, 62.6; H, 5.0; Br, 20.7. $C_{21}H_{20}OBrP$ requires C, 63.15; H, 5.1; Br, 20.0%). A 1.029% solution in aqueous alcohol (2 vols. alcohol: 1 vol. water) had $\alpha_D^{25} + 0.34^\circ$, $[M]_D^{25} + 32.9^\circ$.

Recrystallisation from alcohol failed to affect the m. p. or to cause any significant change in the rotatory power: for a 1.010% solution in aqueous alcohol, $\alpha_D^{25} + 0.34^\circ$, $[M]_D^{25} + 33.7^\circ$ (values for other wave-lengths for a 1.029% solution of this recrystallised material are given in the table on p. 1638) (Found: C, 62.7; H, 4.9; Br, 20.15%).

With methyl alcohol as solvent a marked decrease in rotatory power was observed: a 1.032% solution had $\alpha_D^{25} + 0.05^\circ$, $[M]_D^{25} + 4.8^\circ$. The bromide was recovered from the solution by evaporation in a vacuum and a 0.941% solution of this material in aqueous alcohol had $\alpha_D^{25} + 0.31^\circ$, $[M]_D^{25} + 32.9^\circ$.

The Phosphonium l-Camphorsulphonate.—The phosphonium bromide was recovered from the second and the third fraction of the *d*-camphorsulphonate by precipitation with calcium bromide as described above, and was then converted into the *l*-camphorsulphonate by the usual method. The glass obtained by evaporation of the methyl-alcoholic solution was crystallised from acetone and then had m. p. 152–157°. When recrystallisation was attempted from ethyl acetate-ethyl alcohol, in the proportions used for the *d*-camphorsulphonate, the hot solution initially obtained began to deposit a crystalline precipitate and considerably more alcohol was required before solution could be re-obtained [14 g. of the salt in ethyl acetate (90 c.c.) required 47 c.c. of alcohol]. On cooling, a crystalline precipitate of *l*-camphorsulphonate rapidly separated: 11.8 g., m. p. 170–172°. This had $\alpha_D^{25} - 0.73^\circ$, $[M]_D^{25} - 102^\circ$ for a 0.950% solution in alcohol (Found: C, 68.1; H, 6.3. $C_{21}H_{20}O_2SP$ requires C, 67.6; H, 6.4%). Evaporation of the mother-liquors left a solid residue, m. p. 165–168°, $\alpha_D^{25} - 0.72^\circ$, $[M]_D^{25} - 101^\circ$ for a 0.945% alcoholic solution.

The phosphonium bromide was regenerated from a sample of the first crop; this had m. p. 286–288° and proved to be optically inactive in aqueous-alcoholic solution, in which solvent it was considerably less soluble than the *d*-phosphonium bromide described above.

Repeated attempts to recrystallise the *l*-camphorsulphonate from ethyl acetate-ethyl alcohol showed that it was much less soluble than the *d*-phosphonium *d*-camphorsulphonate, and a product, m. p. 170–172°, was always obtained. It was redissolved in methyl alcohol, the solution taken to dryness, and the glass crystallised from acetone in the hope that the low-melting form could be again obtained, but such methods led invariably to a product, m. p. 170–172°, evidently a partial racemate of the *dl*-phosphonium *l*-camphorsulphonate. In a similar way, further preparations of the *d*-camphorsulphonate led to a high-melting product from which the inactive bromide, m. p. 286–288°, was regenerated.

We are indebted to Mr. F. C. Baker for a considerable amount of assistance in the preparation of chlorophosphines.

UNIVERSITY CHEMICAL LABORATORY, CAMBRIDGE.

[Received, February 10th, 1947.]

327. Reduction by Dissolving Metals. Part V.

By ARTHUR J. BIRCH.

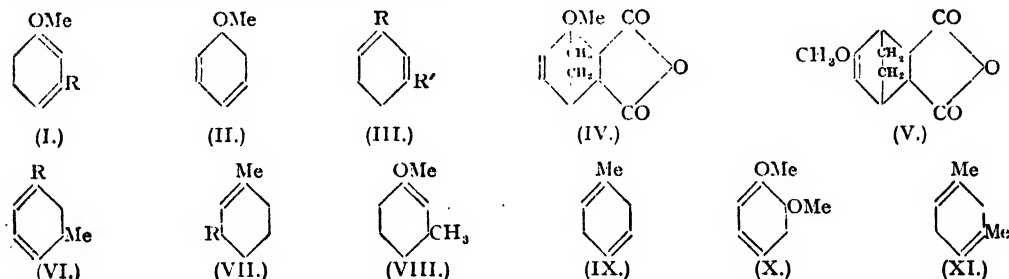

Potassium amide in liquid ammonia conjugates the double bonds of 2:5-dihydroanisoles with formation of 2:3-dihydroanisoles, which give adducts with maleic anhydride and are reduced by sodium in ammonia chiefly to alkylcyclohexenes, but by sodium and alcohol in ammonia chiefly to alkyltetrahydroanisoles. With alkyl-2:5-dihydrobenzenes, instead of the conjugated dienes, the products are chiefly the alkylbenzenes, and the conjugated compound 4:5-dihydro-*m*-xylene gives *m*-xylene under the same conditions. Also observed are the transformations: 2:4-dimethylhexa-1:5-diene \rightarrow 2:4-dimethylhexa-2:4-diene; oct-1-ene \rightarrow oct-2-ene; 4-phenylbut-1-ene \rightarrow 4-phenylbut-2-ene; 3-butoxy-2-methylpropene \rightarrow 1-butoxy-2-methylpropene; 3-methoxycyclohexene \rightarrow a mixture of cyclohexene and benzene; a number of hydrocarbons are unchanged.

The bond migrations are postulated as taking place through anions formed by loss of a proton from an allyl position. The theory is related to the effects of alkyl substitution on the ease of

the process, and applied to a consideration of some reduction phenomena with sodium in ammonia and with calcium hexammine.

IN Part III (*J.*, 1946, 593) it was found that the $\alpha\delta$ -dihydro-derivatives obtained by the reduction with sodium and alcohol in liquid ammonia of methoxyalkyl-, dimethylaminoalkyl-, and alkyl-benzenes were further reduced by sodium and ammonia or by calcium hexammine. Intermediate conjugation of the double bonds was postulated as taking place through a mesomeric anion formed by loss of a proton to the anionoid reagent (either sodium, or calcium hexammine, or the sodium or calcium amide formed in increasing amount as the reaction proceeds). Farmer, Koch, and Sutton (*J.*, 1943, 545) have postulated a similar intervention of mesomeric allylic radicals to explain the formation of conjugated peroxides from non-conjugated dienes in oxidation reactions.

Conjugated compounds have now been produced from the methoxyalkyl- $\alpha\delta$ -dihydrobenzenes by the action of the amides of sodium or potassium in liquid ammonia (the latter preferred because of its solubility); the deep red-brown colour of the solution confirms the formation of a mesomeric carbanion in the process. The products (*e.g.*, I) were identified as conjugated by the formation of crystalline maleic anhydride adducts, by their light absorption at λ_{\max} , *ca.* 2700 Å., and by their ready reduction with sodium and alcohol in ammonia. They must have a disposition of double bonds relative to the methoxyl group of type (I) rather than (II) or (III, R = OMe). Acid hydrolysis produced unsaturated ketones, rather than hydrocarbons, thus eliminating (II), and the maleic anhydride adducts did not behave as the enol ethers of ketones, and were therefore of type (IV) corresponding to (I) rather than of type (V) corresponding to (III, R = OMe). Also, the product from 2:5-dihydro-*p*-tolyl methyl ether must be 2:3-dihydro-*p*-tolyl methyl ether since it gave rise to the 2:4-dinitrophenylhydrazones of 4-methylcyclohex-3- rather than -2-enone.

The conjugated compound from 2:5-dihydro-*m*-tolyl methyl ether is formulated as (I, R = Me) since acid hydrolysis gave 3-methylcyclohex-2-enone, not the alternative 5-methylcyclohex-2-enone to be expected from (VI, R = OMe). Further confirmation came from its reduction products. Sodium and alcohol in ammonia gave a little 1-methylcyclohexene (VII, R = H) and preponderantly 1-methoxy-3-methylcyclohexene (VIII), acid hydrolysis of which produced 3-methylcyclohexanone, and permanganate oxidation α -methyladipic acid. Sodium in ammonia gave mainly (VII, R = H) and a little (VIII). The hydrocarbons similarly obtained from the dihydro-*o*- and -*p*-tolyl methyl ethers were identified by their infra-red absorption spectra as mixtures of methylcyclohexenes: *ortho*-, the 4-methyl- two parts, and the 1- and 3-methyl one part each; *para*-, one part each of the 1-, 3-, and 4-methyl. The 2:5-dihydro-derivatives from 3:5-dimethyl- and 2:6-dimethyl-anisole gave by the prolonged action of sodium in ammonia (doubtless with intermediate conjugation) small amounts of 1-methoxy-3:5- and -2:6-dimethylcyclohexene (hydrolysed by acid to 3:5-dimethyl- and 2:6-dimethyl-cyclohexanone) together with the same hydrocarbon, identified as 2:4-dimethylcyclohexene by comparison of its derivatives with those obtained from an authentic specimen. 1:2-Dimethoxy-3:6-dihydrobenzene gave anisole by the action of potassium amide in ammonia, probably by way of the intermediate (X).

The formation of conjugated derivatives of type (I) can be explained by assuming that a proton is removed from the CH₂ adjacent to the methoxyl group, and that the anion then adds a proton with the final result of pivoting the enol double bond about this group. This is particularly clearly shown by the formation of (I, R = Me) rather than (VI, R = OMe) from dihydro-*m*-tolyl methyl ether. Some dehydrogenation which accompanies the isomerisation may be explained by loss of a hydrogen anion from the intermediate salt (compare the hydrocarbons on p. 1644).

Addition of the alkyl dihydrobenzenes such as 2 : 5-dihydrotoluene (IX) or 2 : 5-dihydro-*m*-xylene (XI) to potassium or sodium amide in liquid ammonia gave a red colour, but the recovered product contained little, if any, of the conjugated diene, the chief constituent being the aromatic hydrocarbon together with a little of the alkyl tetrahydrobenzene and polymeric material. The product obtained by acting on 2 : 5-dihydrotoluene with sodium amide for a short time gave rise to a trace of a maleic anhydride adduct, probably derived from 1-methylcyclohexa-1 : 3-diene, since it was not identical with that obtained from 1-methylcyclohexa-1 : 5-diene. That cyclohexa-1 : 3-dienes themselves can be dehydrogenated by the reagent was shown by the production of *m*-xylene from 4 : 5-dihydro-*m*-xylene, the red colour of the intermediate ion being visible in this case also. These ions must be similar in type to those from the unconjugated dienes, and both can assume the stable aromatic configuration by the expulsion of a hydrogen anion. The dehydrogenation may be compared with the formation of naphthalene and lithium hydride by the action of phenyl lithium on 1 : 4-dihydronaphthalene (Gilman and Bradley, *J. Amer. Chem. Soc.*, 1938, 60, 2333). The source of the small amount of tetrahydrobenzene derivative in the aromatic product is not certain, but in view of the small reducing power of sodium hydride (Swamer and Hauser, *J. Amer. Chem. Soc.*, 1946, 68, 2647) it may have been present in the starting material.

The formation of a considerable proportion of tetrahydrobenzene derivative by the action of sodium in ammonia or of calcium hexamine on the unconjugated compound must have been due to reduction of the conjugated compound as it was produced; this also agrees with the fact that less polymeric material was formed. Even here, however, some aromatic material appeared (see 2 : 5-dihydrotoluene). It is noteworthy that the same ratio of 1- to 3-methylcyclohexene was obtained from toluene or 2 : 5-dihydrotoluene, irrespective of which reduction process was employed, and that reduction of 4 : 5-dihydro-*m*-xylene (III; R, R' = Me) gave 1 : 3-dimethylcyclohexene (VII, R = Me) already obtained from *m*-xylene and 2 : 5-dihydro-*m*-xylene (Part III, *loc. cit.*). The fact that alkylcyclohexenes are unaltered by the reagents makes it possible to draw conclusions about the reduction intermediates from the position of the double bond in these products.

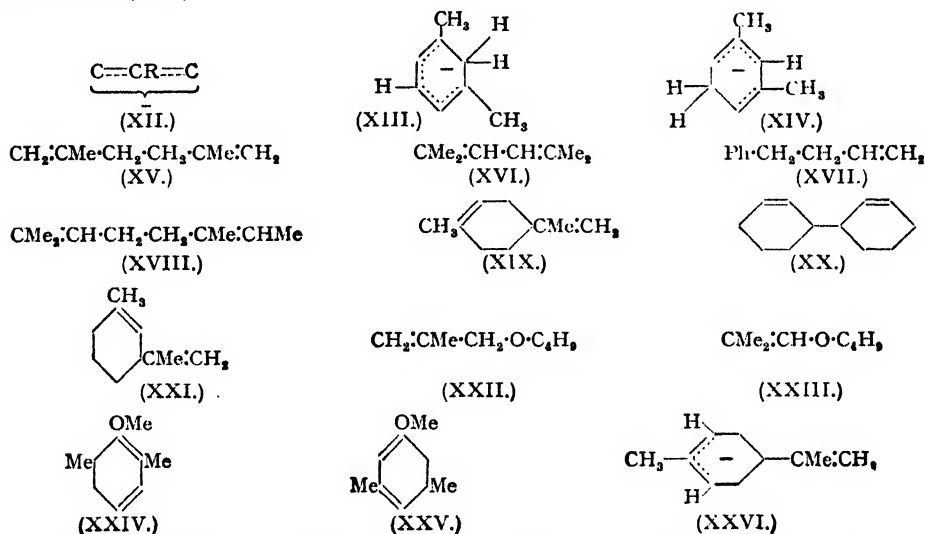

The reason for the observed difference in the rate of dehydrogenation of the dihydroanisole and dihydrobenzene derivatives may be due to the higher energy of the anions with the latter due to the inductive effect of the alkyl groups; this may be correlated with the fact that, although some conjugated material was detected in the case of dihydrotoluene, none was observed with the more highly alkylated dihydro-*m*-xylene. That methoxyl groups have a stabilising effect on anions except when the charge is forced to reside on the occupied or para-carbon atoms is clear from a number of results obtained in Part IV (this vol., p. 102) and from the fact that 2-methoxynaphthalene is reduced mainly in the occupied ring.

Hydrocarbon.	Reagent.	Product.
2 : 5-Dihydrotoluene	KNH ₂ , NH ₃	Toluene; methylcyclohexene (tr.)
2 : 5-Dihydro- <i>m</i> -xylene	KNH ₂ , NH ₃	<i>m</i> -Xylene
4 : 5-Dihydro- <i>m</i> -xylene	KNH ₂ , NH ₃	<i>m</i> -Xylene
Oct-1-ene	KNH ₂ , NH ₃	Oct-1-ene, 80%; oct-2-ene, 20%
2 : 5-Dimethylhexa-1 : 5-diene ...	KNH ₂ , NH ₃	2 : 5-Dimethylhexa-2 : 4-diene
4-Phenylbut-1-ene	KNH ₂ , NH ₃	4-Phenylbut-2-ene(?); polymer
3-Methyl-, 1 : 3-dimethyl-, 2 : 4-dimethyl-cyclohexene; <i>d</i> -limonene, <i>d</i> -sylvestrene, methylgeraniolene, 1 : 2 : 3 : 4 : 1' : 2' : 3' : 4'-octahydrodiphenyl	KNH ₂ , NH ₃ or Ca(NH ₂) ₂	Unchanged
2 : 5-Dihydrotoluene	Na, NH ₃	1-Methylcyclohexene, 50%; toluene, 40%; 3-methylcyclohexene, 10%

Toluene	Ca(NH ₂) ₂	1-Methylcyclohexene, 80%; 3-methylcyclohexene, 20%
4-Phenylbut-1-ene	Na, NH ₃	Phenylbutane

* Part III, *loc. cit.*; the constitution of the product is proved in the present paper.

The ability to conjugate depends on the ability to form the alkali-metal salts and therefore on the presence of a relatively acidic hydrogen atom, which, with the cyclohexadienes, is due to stabilisation of the anion resulting from proton removal by resonance of the charge with the ends of the two double bonds. The production of the conjugated compound on addition of a proton to this ion is, of course, due to the lower energy of the double bonds in conjugation. It has

already been pointed out (Part II, *J.*, 1945, 809) that the lower the degree of alkylation of the end carbon atoms of a mesomeric anion of type (XII) the more readily it is formed, *i.e.*, the more acidic the proton whose removal produces it. This is further confirmed by the work of Morton, Brown, Holden, Letsinger, and Margat (*J. Amer. Chem. Soc.*, 1945, **67**, 2224) on the direct metallation of alkylethylenes. These ideas may be applied to predict that the conjugation of 1:3-dimethyl-2:5-dihydrobenzene (XI), which might proceed through (XIII) or (XIV), should take place through the latter, since the negative charges would reside on less alkylated carbon atoms at the ends of the mesomeric system. This is confirmed by the production of 1:3-dimethylcyclohexene (VII, *R* = Me) by sodium in ammonia reduction, since this could hardly be derived from (XIII) through (VI, *R* = Me), and is given by (III; *R* = *R'* = Me) derivable from (XIV).

With compounds having double bonds insulated from one another by two saturated carbon atoms the conditions for migration are less favourable, since removal of a proton in the allyl position gives an anion in which the charge can resonate with only one double bond. The double bond in oct-1-ene was moved in part to the 2-position, and in this case the mesomeric anion has a low degree of alkylation, having at its ends CH_2 and CHR . This is also true of the initial stage of isomerisation of 2:5-dimethylhexa-1:5-diene (XV) to 2:5-dimethylhexa-2:4-diene (XVI) (the compound has also been reduced by means of calcium hexamine; Kazanskii and Glushnev, *Bull. Acad. Sci. U.R.S.S.*, 1938, 1065) and of the isomerisation of 4-phenylbut-1-ene (XVII) to 1-phenylbut-2-ene and a polymer, probably derived from 1-phenylbut-1-ene; (XVII) was also reduced to phenylbutane by the prolonged action of sodium in ammonia. The second unsaturated centre must have some influence, however, since isomerisation in these cases is much readier than with oct-1-ene. Substitution of the hexa-1:5-diene with saturated carbon atoms at the ends of the potential resonating ion, *e.g.*, in methylgeraniolene (XVIII), *d*-limonene (XIX), and 1:2:3:4:1':2':3':4'-octahydrodiphenyl (XX), prevented isomerisation with potassium amide in ammonia or reduction by calcium hexamine; more surprisingly, sylvestrene (XXI) was also unaffected. Several of these compounds should have relatively acidic hydrogen atoms present in methyl groups, but the anion formed by loss of a proton should merely regenerate the starting material. Production of the anion (XXVI) from *d*-limonene would result in re-formation of the starting material in the racemic form; in fact, the rotation was unaltered. This agrees with the observation that the double bond in alkylcyclohexenes was not moved.

3-Butoxy-2-methylpropene (XXII), the resonating anion from which would contain CH_2 and CHR , was isomerised to 1-butoxy-2-methylpropene (XXIII), but no 1-methoxycyclohexene was obtained from 3-methoxycyclohexene, loss of methyl alcohol producing a hydrocarbon analysing for cyclohexadiene. It gave no reaction with maleic anhydride, and its physical properties indicated a mixture of benzene and cyclohexene.*

* *Added in Proof.*—For a further discussion of the relationship between structure and acidity see Birch, Faraday Society Discussion, 1947, "Labile Molecules" (in the press).

Reduction of the conjugated *cyclohexadienes* can be explained by the initial addition of two electrons to the system. With the hydrocarbons the bivalent anions so formed then abstract two protons from the alcohol or ammonia; in the case of the methoxy-compounds this may occur, and is naturally favoured by the presence of more readily available protons from alcohol, or a methoxyl anion may be expelled with addition of another electron and finally two protons to give an alkylcyclohexene. This seems to be confirmed by the fact that 2-ethoxy-3:4-dihydronaphthalene gave with sodium in ammonia, with or without alcohol, tetrahydronaphthalene as the first recognisable product. It also explains the formation of the same dimethylcyclohexene from the dihydro-derivatives of 2:6- and 3:5-dimethylanisole by way of the conjugated (XXIV) and (XXV), which would give the same anion after expulsion of the methoxyl. It is noteworthy that dimethyl-2:5-dihydro-*m*-toluidine did not give rise to any hydrocarbon, the product containing the tetrahydroamine, and this may be correlated with the greater energy of formation of the dimethylamino- than of the methoxy-anion.

It is necessary to determine the positions of addition of nascent hydrogen to asymmetrical alkylcyclohexadienes before further conclusions can be drawn; evidence is already available that it may occur in both the $\alpha\beta$ - and the $\alpha\delta$ -positions.

EXPERIMENTAL.

Alkyl-2:3-dihydroanisoles.—The alkyl-2:5-dihydroanisoles were prepared from the alkylanisoles by reduction with sodium and alcohol in liquid ammonia as described in Part III (*loc. cit.*) under the preparation of the derived ketones. The compounds (10 g.) were conjugated by dissolving them in a solution of potassium amide (from the metal, 2 g.) in ammonia (100 c.c.) and stirring for 1½ hours. Water was then added very cautiously to the dark red solution, the oil taken up in ether, dried (K_2CO_3), and distilled. It is unlikely that conjugation is brought about by the caustic alkali formed during working up, since it could not be accomplished with boiling 15% alcoholic potassium ethoxide. The maleic anhydride adducts were prepared by addition to excess of the anhydride in benzene and 6 hours' standing. Material boiling up to 120°/10 mm. was then removed, the product extracted from polymeric material in the residue with ether and crystallised from benzene-light petroleum with the aid of a little fuller's earth.

The reduction of the conjugated compounds was carried by two methods. (A) A solution of the substance (5 g.) and sodium (4 g.) in ammonia (70 c.c.) was left for 30 minutes, excess of ammonium chloride added, then water (70 c.c.), and the oil separated with the aid of a centrifuge if necessary; owing to the volatility of the methylcyclohexenes in boiling ammonia only 2–2.5 g. of product were obtained. (B) The substance (10 g.) in ammonia (100 c.c.) and alcohol (10 g.) was gradually reduced by the addition of sodium (6 g.) over 3 hours with stirring, and the product worked up as above.

2:5-Dihydroanisole (b. p. 148–150°) gave 2:3-dihydroanisole (6.2 g.), b. p. 145°, n_D^{18} 1.4902, λ_{max} 2690 Å., ϵ_{max} 4560 (Found: C, 76.1; H, 9.2. $C_7H_{10}O$ requires C, 76.4; H, 9.1%). Cold 2:4-dinitrophenylhydrazine sulphate in alcohol indicated a 91% content of dihydro-compound, and the derivative formed, m. p. 140–146°, appeared to be a mixture of the cyclohex-3-enone derivative, m. p. 134°, and the Δ^2 -derivative, m. p. 167°. Brief refluxing with alcoholic sulphuric acid gave the latter. The maleic anhydride adduct had m. p. 91° (Found: C, 63.3; H, 5.8. $C_{11}H_{12}O_4$ requires C, 63.4; H, 5.8%). This was unaffected by Brady's reagent.

Reduced by method (B), 2:3-dihydroanisole gave 1-methoxycyclohexene, b. p. 140–145°, which readily gave rise to cyclohexanone 2:4-dinitrophenylhydrazone, m. p. 156–157°.

The mixture of 3:6- and 2:5-dihydro-*o*-tolyl methyl ether obtained by reduction of *o*-tolyl methyl ether (Parts I and III, *loc. cit.*) gave a compound (chiefly 2:3-dihydro-*o*-tolyl methyl ether?), b. p. 155–160° (Found: C, 77.3; H, 9.3. $C_9H_{12}O$ requires C, 77.4; H, 9.7%). Continuation of the reaction for 5½ hours gave a product, b. p. 165–167°, which appeared to be mainly *o*-tolyl methyl ether (Found: C, 79.1; H, 8.3. Calc. for $C_9H_{10}O$: C, 78.7; H, 8.2%). Reduction of the conjugated diene mixture by method (A) gave a fraction, b. p. 100–104°, shown by its infra-red absorption to contain a mixture of methylcyclohexenes: Δ^2 -two parts, Δ^1 - and Δ^2 -one part each.

2:5-Dihydro-*m*-tolyl methyl ether gave 5:6-dihydro-*m*-tolyl methyl ether, b. p. 165–167° (Found: C, 77.6; H, 9.7. $C_9H_{12}O$ requires C, 77.4; H, 9.7%). The maleic anhydride adduct crystallised from benzene-light petroleum in prisms, m. p. 77° (Found: C, 65.2; H, 6.3. $C_{13}H_{14}O_4$ requires C, 64.9; H, 6.3%). Treatment with 2:4-dinitrophenylhydrazine sulphate in hot alcohol gave the derivative of 3-methylcyclohex-2-enone, m. p. 174–175°. Reduction by method (A) gave chiefly a fraction, b. p. 106–110°, n_D^{18} 1.4500 (Found: C, 87.4; H, 12.5. Calc. for C_9H_{12} : C, 87.5; H, 12.5%). The nitropiperidine, m. p. 146–147°, and its infra-red absorption spectrum showed this hydrocarbon to be 1-methylcyclohexene. A small fraction, b. p. 155–162°, gave rise to the 2:4-dinitrophenylhydrazone of 3-methylcyclohexanone, m. p. 154°, and a few drops of material, b. p. 162–172°, appeared to contain *m*-tolyl methyl ether. Reduction by method (B) gave a trace of a fraction (i) b. p. 110–115°, and mainly 1-methoxy-3-methylcyclohexene (ii), b. p. 156–160°, n_D^{18} 1.4660. Hydrolysis of this by boiling with 10% sulphuric acid for an hour, conversion of the oil into a solid bisulphite compound, and regeneration gave 3-methylcyclohexanone, b. p. 165°; 2:4-dinitrophenylhydrazone m. p. 155°, semicarbazone m. p. 180°. Oxidation of (ii) with potassium permanganate in acetone gave an acid which did not crystallise, but readily formed the dianilide of α -methyladipic acid, m. p. 173° (Found: C, 73.7; H, 7.4. Calc. for $C_{13}H_{22}O_2N_2$: C, 73.5; H, 7.1%). Bouveault and Locquin (*Bull. Soc. chim.*, 1908, 3, 451) give m. p. 174–175°.

2:5-Dihydro-*p*-tolyl methyl ether (b. p. 168–170°) gave 2:3-dihydro-*p*-tolyl methyl ether, b. p. 165–167°, λ_{max} 2720, ϵ_{max} 4060 (Found: C, 77.6; H, 9.7. $C_9H_{12}O$ requires C, 77.4; H, 9.7%), giving

with cold Brady's reagent the 2:4-dinitrophenylhydrazone of 4-methylcyclohex-3-enone, m. p. 122°, converted by hot dilute alcoholic sulphuric acid into the derivative of 4-methylcyclohex-2-enone, m. p. 174°. The maleic anhydride adduct had m. p. 85–86° (Found: C, 64.8; H, 6.3. $C_{12}H_{14}O_4$ requires C, 64.9; H, 6.3%). Reduction by method (A) gave a hydrocarbon fraction, b. p. 103–105° (Found: C, 87.3; H, 12.7. Calc. for C_8H_{14} : C, 87.5; H, 12.5%). This was shown by its infra-red absorption to contain about one part each of 1-, 3-, and 4-methylcyclohexene. Reduction by method (B) gave chiefly a fraction (1-methoxy-4-methylcyclohexene), b. p. 157–162° (Found: C, 76.0; H, 10.6. $C_8H_{14}O$ requires C, 76.2; H, 11.1%), which on acid hydrolysis and bisulphite purification gave 4-methylcyclohexanone, b. p. 165–167°, semicarbazone m. p. 196°.

In order to investigate the ease of dehydrogenation in this case the conjugation reaction was continued for (i) 2½ hours and (ii) 5½ hours, giving as the products: (i), b. p. 165–167° (Found: C, 77.4; H, 9.8. Calc. for $C_8H_{14}O$: C, 77.4; H, 9.7%), λ_{max} 2720, ϵ_{max} 3640; and (ii), b. p. 165–170° (Found: C, 77.9; H, 9.3. Calc. for $C_8H_{14}O$: C, 77.4; H, 9.7%). The latter by estimation with Brady's reagent showed only about a 50% content of methylidihydroanisole. Dehydrogenation had thus taken place, although to a smaller extent than with the dihydro-*o*-tolyl methyl ether.

2:6-Dihydroveratrole (Part IV, *loc. cit.*) gave rise to anisole, b. p. 145–150°, unaffected by Brady's reagent and demethylated to phenol.

Reduction of 3:5- and 2:6-Dimethylanisole.—These compounds (10 g.) were reduced in ammonia (100 c.c.) with sodium (5 g.) and alcohol (5 g.), a further amount of sodium (5 g.) added, and the mixture left for 10 hours and worked up as usual.

3:5-Dimethylanisole gave (i), b. p. 125–130° (2.4 g.), and (ii), b. p. 185–195°. Fraction (i) gave a good yield of a nitropiperidine as colourless prisms from methyl alcohol, m. p. 146–147° (Found: C, 69.4; H, 10.6. $C_{13}H_{24}ON_2$ requires C, 69.6; H, 10.7%), undepressed by the derivative of 2:4-dimethylcyclohexene. Fraction (ii) seemed to be largely starting material, but reacted with Brady's reagent to give the 2:4-dinitrophenylhydrazone of 3:5-dimethylcyclohexanone, m. p. 155–157° (Found: C, 54.2; H, 6.0. $C_{14}H_{24}O_4N_4$ requires C, 54.7; H, 6.1%). Two stereoisomers are possible, and there is no evidence as to whether one or a mixture was present.

2:6-Dimethylanisole gave (i), b. p. 125–130° (1.1 g.), and (ii), b. p. 160–170° (0.5 g.), together with a higher fraction of starting material. Fraction (i) gave the nitropiperidine, m. p. 146–147°, of 2:4-dimethylcyclohexene. Fraction (ii) gave the 2:4-dinitrophenylhydrazone of 2:6-dimethylcyclohexanone, m. p. 149–150°, also possibly a mixture of stereoisomers (Found: C, 55.0; H, 5.9. $C_{14}H_{24}O_4N_4$ requires C, 54.7; H, 6.1%).

The 2:4-dimethylcyclohexene required for comparison was synthesised by reducing *m*-4-xyleneol with Raney nickel and hydrogen at 150°/100 atm., esterifying the resulting 2:4-dimethylcyclohexanol with palmitic acid, and distillation of the ester at 340–350°. It had b. p. 124–125° (Found: C, 87.1; H, 12.7. Calc. for C_8H_{14} : C, 87.3; H, 12.7%). In order to ensure that no movement of the double bond had taken place, the hydrocarbon was oxidised with potassium permanganate in acetone, and the resulting acid gave β -methyladipic dianilide, m. p. 198° (Found: C, 73.0; H, 7.2. Calc. for $C_{19}H_{22}O_2N_2$: C, 73.5; H, 7.1%). Markownikoff (*J. Russ. Phys. Chem. Soc.*, 1903, **35**, 226) gives m. p. 197–198°. Addition of nitrosyl chloride gave a solid which was refluxed with sodium acetate in acetic acid and hydrolysed with dilute mineral acid to a ketone, b. p. 93–96°/16 mm. (cf. Wallach, *Annalen*, 1913, **395**, 275; **397**, 198). This gave rise to a 2:4-dinitrophenylhydrazone as bright red needles (from ethyl acetate-alcohol), m. p. 183–184° (Found: C, 55.0; H, 5.4. $C_{14}H_{18}O_4N_4$ requires C, 55.3; H, 5.3%), which must be derived from 2:4-dimethylcyclohex-2-enone, since it is not identical with the derivatives from 2:6-dimethyl-, m. p. 153°, from 3:5-dimethyl-, m. p. 165°, or from 4:6-dimethylcyclohex-2-enone, m. p. 164–165°. The semicarbazone had m. p. 167–168° (Found: C, 59.5; H, 8.3. Calc. for $C_8H_{14}ON_3$: C, 59.7; H, 8.3%). This examination was necessary, since Wallach (*loc. cit.*) gives m. p. 130–131° for the nitropiperidine and m. p. 194–195° for the semicarbazone obtained as above.

Methylallyl butyl ether, obtained from sodium *n*-butoxide and methylallyl chloride, b. p. 135–137°, n_D^{20} 1.3942, gave 1-butoxy-2-methylpropene, b. p. 138–140°, n_D^{20} 1.4230 (Found: C, 75.0; H, 12.6. $C_8H_{16}O$ requires C, 75.0; H, 12.5%), which, unlike the starting material, gave the 2:4-dinitrophenylhydrazone of isobutaldehyde on boiling with Brady's reagent, m. p. 182° (Found: C, 47.6; H, 4.8. Calc. for $C_{10}H_{18}O_4N_4$: C, 47.4; H, 5.1%). Mathiessen and Hagedorn (*Mikrochem.*, 1941, **29**, 58) give m. p. 183.5–185°.

3-Methoxycyclohexene (Berlande, *Bull. Soc. chim.*, 1942, **9**, 653) gave a hydrocarbon, b. p. 78–82°, n_D^{20} 1.4720 (Found: C, 89.6; H, 10.4. Calc. for C_8H_{12} : C, 90.0; H, 10.0%). It was unsaturated, but did not react with maleic anhydride and was probably a mixture of cyclohexene and benzene. A small higher-boiling fraction contained no 1-methoxycyclohexene since it failed to react with Brady's reagent.

Action of Sodium or Potassium Amide on Unsaturated Hydrocarbons.—The metal (2 g.) in ammonia (100 c.c.) was converted into the amide by the catalytic action of ferric nitrate, the hydrocarbon (10 g.) added, and the mixture stirred for 6 hours with exclusion of air. The product was worked up by addition of ice and ether extraction; in many cases considerable loss of material occurred by volatilisation.

2:5-Dihydrotoluene was obtained by reduction of toluene with sodium and alcohol in liquid ammonia (cf. dihydro-*m*-xylene, Part III); b. p. 114–115°, n_D^{20} 1.4695 (Found: C, 89.2; H, 10.7. C_8H_{10} requires C, 89.4; H, 10.6%), nitropiperidine m. p. 122–123°. It gave rise to a product, b. p. 108–110°, n_D^{20} 1.4890 (Found: C, 90.4; H, 9.3. Calc. for C_7H_8 : C, 91.3; H, 8.7%. Calc. for C_7H_{12} : C, 87.5; H, 12.5%). This gave a small yield of the nitropiperidine, m. p. 146–147°, of 1-methylcyclohexene, and must consist of an admixture of a trace of this with toluene. After treatment of 2:5-dihydrotoluene with sodium amide in ammonia for one hour the product (b. p. 108–112°) was left with maleic anhydride in cold acetone for 5 hours and then steam-distilled. The small residue crystallised and the adduct was recrystallised from aqueous methanol; m. p. 62–63° (Found: C, 68.5; H, 6.2. $C_{11}H_{12}O_3$ requires C, 68.8; H, 6.2%). Brief heating on the steam-bath with *p*-toluidine gave a derivative, m. p. 182° (from alcohol) (Found: C, 77.2; H, 6.7. $C_{18}H_{18}O_2N$ requires C, 76.8; H, 6.7%). For comparison the derivative of 1-methylcyclohexa-1:5-diene was synthesised from cyclohex-2-enone by the action of methylmagnesium iodide, dehydration of the carbinol by distillation with a trace of iodine, and treatment

of the product (b. p. 110°) with maleic anhydride in cold acetone. The adduct, b. p. 180°/16 mm., solidified in ice and melted at about 14° (Found: C, 68.8; H, 6.0. $C_{11}H_{18}O_2$ requires C, 68.7; H, 6.2%). The derivative obtained with *p*-toluidine had m. p. 175° (from alcohol), depressed by the above (Found: C, 76.4; H, 6.9. $C_{11}H_{18}O_2N$ requires C, 76.8; H, 6.7%).

2:5-Dihydro-*m*-xylene (Part I) gave *m*-xylene, b. p. 136–138°, n_D^{18} 1.4960, and no conjugated material could be detected.

4:5-Dihydro-*m*-xylene, b. p. 135°, was obtained by the action of methylmagnesium iodide on 3-methylcyclohex-2-enone followed by dehydration of the carbinol by distillation with a trace of iodine. It gave rise to a colourless oil, b. p. 135–137° (Found: C, 90.2; H, 9.7. Calc. for C_9H_{16} : C, 90.5; H, 9.5%). The ultra-violet absorption of this was consistent with its being a mixture of 80% of *m*-xylene and 20% of starting material.

Oct-1-ene was prepared by the action of amylmagnesium bromide on allyl bromide (cf. Henne, Chanan, and Turk, *J. Amer. Chem. Soc.*, 1941, **63**, 3474); b. p. 119°. It gave rise to a product, b. p. 119–122°, which was shown by its infra-red absorption spectrum to contain 80% of oct-1-ene and 20% of an isomer, probably oct-2-ene.

2:5-Dimethylhexa-1:5-diene (*idem, ibid.*), b. p. 114°, n_D^{18} 1.4360, gave rise to 2:5-dimethylhexa-2:4-diene, b. p. 133–135°, n_D^{18} 1.4780, m. p. 13°. Henne and Turk (*J. Amer. Chem. Soc.*, 1942, **64**, 826) give for this substance b. p. 134.5°, n_D^{20} 1.4781, m. p. 14°.

4-Phenylbut-1-ene (obtained by the action of benzylmagnesium chloride on allyl bromide) when treated as above gave the red colour but the product was largely high-boiling, probably produced by the polymerisation of phenylbut-1-ene. By limiting the reaction time to 2 hours some polymer was formed together with a product, b. p. 175–182° (Found: C-Me, 7.3. Calc. for $C_9H_9CH_3$: C-Me, 11.4%). From the b. p. it was probably a mixture containing a considerable proportion of phenylbut-2-ene.

Methylgeraniolene, b. p. 167°; *d*-limonene, b. p. 175°, n_D^{20} + 73.5°; *d*-sylvestrene, b. p. 173.5°, n_D^{20} + 17°; and 1:2:3:4:1':2':3':4'-octahydrotetraphenyl (Berlande, *loc. cit.*), b. p. 232–235° (used in ether, 50 c.c., because of its low solubility in ammonia), were all recovered unchanged, the product from the last substance failing to show any reaction with maleic anhydride, and the optical rotations of the active compounds were unchanged. 1:3- and 2:4-Dimethylcyclohexene gave their characteristic nitroloperidines after treatment, and 4-methylcyclohexene showed unaltered infra-red absorption.

Reduction of Hydrocarbons.—2:5-Dihydrotoluene (10 g.) and sodium (5 g.) in ammonia (100 c.c.) after 4 hours gave a product, b. p. 105–110°, n_D^{18} 1.4731 (Found: C, 89.4; H, 10.4%), shown by its infra-red absorption to contain 40% of toluene, 50% of 1-methylcyclohexene, and 10% of 3-methylcyclohexene.

2:5-Dihydrotoluene (10 g.) with calcium hexamine (from the metal, 10 g.) over 48 hours gave a product, b. p. 104–108°, n_D^{20} 1.4470 (Found: C, 87.3; H, 12.3. Calc. for C_7H_{12} : C, 87.5; H, 12.5%), which contained about 80% of 1- and 20% of 3-methylcyclohexene (infra-red absorption). Reduction of toluene by the same method gave a product still containing aromatic material, and the process was repeated on this using the hexamine from calcium (5 g.) and a mixture identical with the above obtained (infra-red absorption).

4:5-Dihydro-*m*-xylene (3.5 g.) was reduced with sodium (2 g.) and alcohol (4 g.) in ammonia (45 c.c.), giving a product, b. p. 124–126° (Found: C, 86.8; H, 12.3. Calc. for C_9H_{14} : C, 87.3; H, 12.7%). That it was chiefly 1:3-dimethylcyclohexene was shown by the preparation of the nitroloperidine, m. p. 156–157°. For comparison, the hydrocarbon was prepared by distilling the palmitate of 2:6-dimethylcyclohexanol at 330–350°; b. p. 125–126° (Found: C, 87.2; H, 12.7. Calc. for C_9H_{14} : C, 87.3; H, 12.7%). This gave the nitroloperidine, m. p. 156–157°, also obtained from the reduction products of *m*-xylene and 2:5-dihydro-*m*-xylene (Part III, *loc. cit.*). Removal of hydrogen chloride from the nitroschloride by means of sodium acetate in boiling acetic acid (cf. Wallach, *loc. cit.*) and treatment of the resulting oxime with Brady's reagent gave the derivative of 2:6-dimethylcyclohex-2-enone, m. p. 153°, already obtained from the reduction product of 2:6-dimethylanisole (Part I, *loc. cit.*), thus confirming the position of the double bond in the hydrocarbon. Dehydration of 2:6-dimethylcyclohexanol with acid reagents such as phosphoric oxide produced considerable isomerisation to give 2:4-dimethylcyclohexene.

4-Phenylbut-1-ene (10 g.) and sodium (5 g.) in liquid ammonia (100 c.c.) were left for 5 hours, excess of sodium destroyed with ammonium chloride, and the product worked up as usual. Distillation gave an oil, b. p. 177–182°, which was shaken with ice-cold aqueous potassium permanganate until a permanent colour was obtained. The distilled oil (4 g.) was phenylbutane, b. p. 179–181° (Found: C, 90.3; H, 10.1. Calc. for $C_{10}H_{14}$: C, 89.6; H, 10.4%).

1:3-Dimethyl- and 2:4-dimethylcyclohexene, *d*-limonene, and *d*-sylvestrene were unchanged by sodium in ammonia or by calcium hexamine, as shown by unchanged physical constants, in particular the optical rotations of the last two substances. Methylgeraniolene and 4-methylcyclohexene were also shown by means of their infra-red absorption to be unchanged.

2-Ethoxy-3:4-dihydronaphthalene (kindly presented by Mr. C. T. Beer), reduced with sodium (4 equivs.) and ammonia either in presence or in absence of alcohol (5 equivs.), gave a hydrocarbon as the product. Obtained in presence of alcohol, this showed slight unsaturation to bromine, but with sodium alone it was 1:2:3:4-tetrahydronaphthalene, b. p. 202–208° (Found: C, 90.6; H, 9.3. Calc. for $C_{10}H_{12}$: C, 90.9; H, 9.1%). When only 2 equivs. of sodium were employed the product was a mixture of about equal parts of tetralin and starting material.

The author wishes to express his gratitude to Dr. D. H. Whiffen and Dr. R. E. Richards for measuring and interpreting the infra-red spectra, and to Dr. F. B. Strauss for the ultra-violet spectrum measurements, which were carried out in alcohol.

This work was carried out during the tenure of an I.C.I. Research Fellowship.

THE DYSON PERRINS LABORATORY, OXFORD UNIVERSITY.

[Received, February 18th, 1947.]

328. Cinnolines. Part XIV. N-Oxides of 4-Arylcinnolines. Conversion of 4-Substituted Cinnolines into Indoles.

By C. M. ATKINSON and J. C. E. SIMPSON.

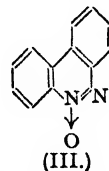

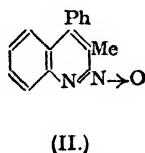

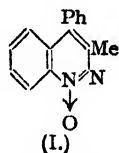

Treatment of 4-arylcinnolines with hydrogen peroxide in acetic acid gives the corresponding N-oxides. In contrast to 3:4-benzocinnoline N-oxide (III) (King and King, *J.*, 1945, 824), 4-phenyl-3-methylcinnoline N-oxide (I) is not nitrated selectively, four isomeric mono-nitro-derivatives being obtained.

Alkaline reduction of 4-substituted cinnolines leads to formation of the corresponding indoles; with 6- and 7-chloro-3-methylcinnoline reductive dehalogenation also occurs, and skatole is produced.

ALTHOUGH formally comparable cinnolines, quinolines, and quinazolines have certain reactions in common, this is not always so (cf. Schofield and Simpson, *J.*, 1946, 472; Simpson, *J.* 1946, 1035; and unpublished work), and in attempting to account for the properties of certain types of cinnoline derivatives, the following * experiments were carried out to examine the possibility that this heterocyclic group might retain some of the characteristics of azo-compounds.

In the first place, we have found that 4-arylcinnolines are readily converted into N-oxides on treatment with hydrogen peroxide in acetic acid. This reaction was tried with 4-phenyl-3-methyl-, 4-phenyl-3-benzyl-, 3-phenyl-4-*p*-anisyl-, 4-*p*-anisyl-3-methyl-, and 3:4-diphenylcinnoline, and in each case the corresponding N-oxide was isolated in good yield. This result was not of direct diagnostic value, for although the oxidation of azo- to azoxy-compounds can be effected under somewhat similar conditions (*Chem. Reviews*, 1931, 9, 126), the formation of N-oxides is likewise characteristic of many heterocyclic types, *e.g.*, pyridines and quinolines (Meisenheimer, *Ber.*, 1926, 59, 1848), phenanthrolines (Linsker and Evans, *J. Amer. Chem. Soc.*, 1946, 68, 403), and quinoxalines (McIlwain, *J.*, 1943, 322; Linsker and Evans, *loc. cit.*, and *p.* 874), although the cinnoline N-oxides, in contrast to the quinoxaline derivatives (McIlwain, *loc. cit.*), showed complete absence of peroxidic properties.

Our experiments with 4-methylcinnolines (this vol., *p.* 808) and with certain N-alkylcinnolinium salts (following paper) have indicated that the cinnoline N-oxides should be formulated as (I) and not as (II). If (I) is properly regarded as a vinylogue of an azoxy-compound, it should undergo preferential substitution in the 4-phenyl group. The nitration of (I) was therefore examined, but proved to be unexpectedly complex, and gave rise to four isomers, designated α -, β -, γ -, and δ -nitro-4-phenyl-3-methylcinnoline N-oxide; there was no evidence of the formation of dinitro-compounds.

No definite conclusion regarding the azoxy-compound-like nature of 4-arylcinnoline N-oxides can be drawn from these results, but the complete lack of any selective attack on the molecule was unexpected, and is in marked contrast to the results of King and King (*J.*, 1945, 824) which appeared after the present work had been discontinued. These workers investigated the nitration of 3:4-benzocinnoline N-oxide (III), and, arguing from essentially the same premises as ourselves, anticipated and encountered nitration almost exclusively in one position, which was assumed to be in the ring remote from the N-oxide linkage.

As an alternative approach to the discovery of azo-compound characteristics in 4-substituted cinnolines, we turned our attention to the reduction of such compounds with sodium and alcohol. 4-Phenyl-3-methylcinnoline gave a mixture of unchanged material (1 part) and 3-phenyl-2-methylindole (2.5 parts), and when the reaction was extended to other compounds it was evident that indole formation, accompanied by evolution of ammonia, is the predominating reaction. The results are summarised in the following table, in which the figures (representing ammonia values expressed as percentages of the amounts corresponding to complete conversion into indole) indicate the extent of the reaction. Examination of the products of reduction gave the following results. From (i) only the indole was isolated. In experiments (ii) and (vi) both the indole and unchanged material were identified. Experiment (v) gave an oil,

* It has been necessary temporarily to discontinue our study of 4-arylcinnolines, and the experiments with such compounds recorded in this and the following paper are therefore incomplete.

(iii) gave an unidentified mixture, and (iv) gave an oil together with unchanged cinnoline. Skatole and 4-methylcinnoline were obtained from (vii) and also from (ix), and (viii) yielded skatole and (as picrate) a substance which was not identical with the picrate of 4-methylcinnoline or of its 6- and 7-chloro-derivatives.

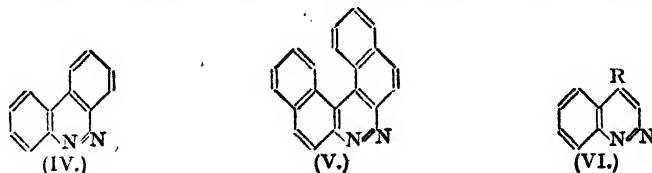

Cinnoline.	NH ₃ evolved, %.	Cinnoline.	NH ₃ evolved, %.
(i) 4- <i>p</i> -Anisyl-3-methyl-	58	(vi) 4- <i>p</i> -Hydroxyphenyl-	53
(ii) 4- <i>p</i> -Hydroxyphenyl-3-methyl- ...	55	(vii) 4-Methyl-	65
(iii) 3-Phenyl-4- <i>p</i> -anisyl-	3	(viii) 6-Chloro-4-methyl-	57
(iv) 3-Phenyl-4- <i>p</i> -hydroxyphenyl- ...	1	(ix) 7-Chloro-4-methyl-	60
(v) 4- <i>p</i> -Anisyl-	15		

The production of 3-methylindole from each of the 4-methylcinnolines is noteworthy. It is possible that the chloro-indole may be formed and may then undergo further reduction, but the results of (ix) indicate that, in this case at least, dehalogenation of the cinnoline occurs more readily than ring-contraction. The unidentified picrate from (viii) might well be that of 5-chloro-3-methylindole, but owing to interruption of the work it has not been possible to investigate this point.

The *indoles* obtained from (i), (ii), and (vi) are apparently new compounds, and their orientation is based on the assumption (which appears to be justified by the formation of skatole and 3-phenyl-2-methylindole) that the ring-contraction is not accompanied by any form of molecular rearrangement.

A comparison of (i) with (v) and of (v) with (vi) suggests that a 3-methyl group and a *p*-hydroxyl group (in the 4-phenyl substituent) both favour the reaction as compared with hydrogen and a methoxyl group respectively; a 3-phenyl group, on the other hand, has a strongly inhibitory effect in conjunction with a 4-aryl group. The contrast between (v) and (vi—ix) seems to indicate that the normal electromeric effect of the 4-substituent is not the sole controlling influence, and it is possible that chemical and spatial factors are both involved. This conclusion is supported by the following evidence from the literature, which, taken in conjunction with our own results, indicates that the tendency of cinnolines to pass into indoles is markedly dependent on the nature and degree of substitution in the pyridazine ring.

(a) Neber, Knöller, Herbst, and Trissler (*Annalen*, 1929, 471, 113), working with various acid reducing media, found that 4-phenylcinnoline yielded 3-phenylindole *via* 4-phenyl-1:2-dihydrocinnoline, and that oxindole was formed from 3-hydroxycinnoline; no indoxyl or indigo derivative resulted, however, from 4-hydroxycinnoline, which (with hydriodic acid and red phosphorus) gave 4-hydroxytetrahydrocinnoline hydriodide. (b) 3:4-Benzocinnolines of type (IV) are more stable, as they are themselves produced from 2:2'-dinitrodiaryls by reduction in alkaline or acid media or electrolytically (Täuber, *Ber.*, 1891, 24, 3081; Meyer, *ibid.*, 1893, 26, 2238; Ullmann and Dieterle, *ibid.*, 1904, 37, 23), and 5:6-benzo-1':2':4:3-naphthocinnoline (V) is also formed in an alkaline reducing medium (from β -nitronaphthalene; Meisenheimer and Witte, *Ber.*, 1903, 36, 4153). (c) If it is assumed that the ammonia evolved in the cinnoline \rightarrow indole reaction is formed by ring-closure of an intermediate diamine, then

a comparable variation in stability may also be discerned among the diamines corresponding to types (VI), (IV), and (V). Thus the diamines derived from a 4-substituted cinnoline (VI; R = Ar or Me) do not survive the reaction conditions used (sodium and alcohol), but they have been isolated from compounds of type (IV) (King and King, *loc. cit.*) and from (V) (Meisenheimer and Witte, *loc. cit.*). (d) Formation of the pyridazine ring [regeneration of type (IV)] from 2:2'-diaminodiaryls occurs at least as readily (Täuber, *Ber.*, 1893, 26, 1703; 1896, 29, 2270; Dobbie, Fox, and Gauge, *J.*, 1911, 1615; Sandin and Cairns, *J. Amer. Chem. Soc.*, 1936, 58, 2016) as does the conversion of such compounds into carbazoles (formation of the pyrrole ring) (Täuber, *loc. cit.*; Meisenheimer and Witte, *loc. cit.*; Dobbie, Fox, and Gauge, *loc. cit.*; King and King, *loc. cit.*). Such variations in stability of the diamines are presumably an indication of the greater degree of ring-strain involved in the carbazole, as compared with the indole, nucleus.

EXPERIMENTAL.

(Melting points are uncorrected.)

4-*p*-Hydroxyphenyl-3-methylcinnoline.—4-*p*-Anisyl-3-methylcinnoline (5 g.; *J.*, 1946, 673) was refluxed with hydrobromic acid (37 c.c., *d* 1.5) for 1 hour. The cold mixture was basified (ammonia), the supernatant liquid decanted, and the solid dissolved in aqueous sodium hydroxide, and the combined alkaline solutions were made acid with acetic acid. 4-*p*-Hydroxyphenyl-3-methylcinnoline (yield of almost pure compound, 4.4 g.) separated from alcohol in small yellow prisms, m. p. 241–242° (Found: N, 12.2. $C_{13}H_{11}ON_2$ requires N, 11.9%); its solution in warm 2*N*-sodium hydroxide deposited silky needles of the sodium salt on cooling.

4-*p*-Hydroxyphenylcinnoline.—4-*p*-Anisylcinnoline was prepared by the method of Stoermer and Gaus (*Ber.*, 1912, 45, 3104), but as a result of its poor crystallising properties was difficult to purify and was most conveniently handled as the hydrochloride, which crystallised well from acetic acid or 2*N*-hydrochloric acid in bright yellow needles, m. p. 215–217° (decomp.) after shrinking at 195°. The salt (15 g.) was refluxed for 1 hour with hydrobromic acid (105 c.c., *d* 1.45) and the crude hydroxyphenylcinnoline isolated as described above. It was best purified by way of the *acetoxy*-compound [obtained by refluxing the crude base with acetic anhydride (5 parts) for $\frac{1}{2}$ hour], which separated from aqueous alcohol in pale yellow rectangles, m. p. 127.5–128° (Found: C, 72.35; H, 4.8; N, 11.35. $C_{16}H_{13}O_2N_2$ requires C, 72.7; H, 4.6; N, 10.6%), and when boiled with 5*N*-hydrochloric acid was rapidly hydrolysed with quantitative separation of 4-*p*-hydroxyphenylcinnoline hydrochloride, m. p. 270–273° (decomp.); this when boiled with water gave the free base as yellow prisms (from alcohol), m. p. 234–235° (Stoermer and Gaus, *loc. cit.*, give m. p. 230°).

3-Phenyl-4-*p*-hydroxyphenylcinnoline.—3-Phenyl-4-*p*-anisylcinnoline (5.5 g.; *J.*, 1946, 673) was refluxed with hydrobromic acid (55 c.c., *d* 1.5) and acetic acid (27.5 c.c.) for 2½ hours; the mixture was cooled, basified with ammonia, and the base recrystallised from acetic acid. 3-Phenyl-4-*p*-hydroxyphenylcinnoline (yield of almost pure compound, 4.9 g.) formed almost colourless needles (occasionally thin parallelepipeds), m. p. 283–286° (Found: C, 80.3; H, 4.9. $C_{20}H_{14}ON_2$ requires C, 80.5; H, 4.7%).

Preparation of Cinnoline N-Oxides.—The cinnolines (1 part) were dissolved in glacial acetic acid (8–10 parts), hydrogen peroxide (5–8 parts, 30%) added, and the clear solutions heated at 90–95° for 2 hours; the products separated on cooling and, if necessary, dilution with water (yields, 80–90%). 4-Phenyl-3-methylcinnoline N-oxide formed long straw-coloured needles, m. p. 124–125°, from aqueous alcohol or aqueous acetic acid (Found: C, 75.85; H, 5.2; N, 12.0. $C_{15}H_{11}ON_2$ requires C, 76.25; H, 5.1; N, 11.9%). 4-Phenyl-3-benzylcinnoline N-oxide, colourless needles from aqueous alcohol, had m. p. 110–111° to a turbid melt which cleared at 130° (Found: C, 80.4; H, 4.8; N, 9.4. $C_{21}H_{16}ON_2$ requires C, 80.7; H, 5.2; N, 9.0%). 3:4-Diphenylcinnoline N-oxide formed radial clusters of stout yellow prismatic needles, m. p. 196–198° (clear at 202°), from ethyl acetate or acetic acid, and was very sparingly soluble in alcohol (Found: C, 80.4; H, 4.65; N, 9.5. $C_{20}H_{14}ON_2$ requires C, 80.5; H, 4.7; N, 9.4%). 4-*p*-Anisyl-3-methylcinnoline N-oxide separated from aqueous acetic acid in colourless blades, m. p. 161° (Found: C, 71.9; H, 5.0. $C_{16}H_{11}O_2N_2$ requires C, 72.1; H, 5.3%). 3-Phenyl-4-*p*-anisylcinnoline N-oxide, light brown blades from aqueous alcohol, had m. p. 176–177° (Found: C, 77.1; H, 4.85. $C_{21}H_{16}O_2N_2$ requires C, 76.8; H, 4.9%).

Nitration of 4-Phenyl-3-methylcinnoline N-Oxide.—The substance (1.5 g.) was added during 35 minutes to 9 c.c. of a mixture of nitric acid (10.5 c.c., *d* 1.48) and sulphuric acid (3 c.c., *d* 1.84). After a total of 1½ hours (reaction temperature –13° to –10° throughout the experiment) the solution was poured into water and the precipitated solid filtered off, washed, and digested with alcohol (1.55 g., m. p. ca. 160–175°). Material so obtained, representing 2.5 g. of cinnoline oxide, was digested with acetone, and the insoluble fraction repeatedly crystallised from a large volume of this solvent; α -nitro-4-phenyl-3-methylcinnoline N-oxide was thus obtained in faintly yellow, microcrystalline nodules, m. p. 256–257° (Found: C, 64.0; H, 3.95; N, 15.2. $C_{16}H_{11}O_3N_2$ requires C, 64.0; H, 3.95; N, 14.9%). This compound was very much less soluble in acetone than the isomers described below; it was insoluble in hot aqueous sodium hydroxide and in 2*N*-hydrochloric acid, and sparingly soluble in hot 6*N*-hydrochloric acid.

Attempted fractional crystallisation (from benzene and acetone) of the material in the acetone filtrates from the α -compound gave only a little impure β -compound. A benzene solution (200 c.c.) of the combined fractions was drawn through a 26 cm. column of Merck's alumina (50 g.) prepared with benzene (80 c.c.). The filtrate and successive washings (50 c.c. portions of benzene) were separately evaporated, yielding respectively (a) 80 mg., (b) 530 mg., (c) 530 mg., (d) 290 mg., (e) 140 mg., and (f) 80 mg. Fractions (a) and (b) were solid, (c) and (d) semi-crystalline, and (e) and (f) were brown resins.

A solution of fraction (b) in acetone, after removal of a little impure α -compound, gave a product which, after repeated crystallisation from acetone and finally from ethyl acetate, yielded the β -isomer as pale yellow, brittle, hexagonal plates, m. p. 235–238° after previous shrinking (Found: C, 63.7; H, 3.75; N, 15.05%).

Fraction (c) was similarly freed from a little α -compound; recrystallisation (finally from slightly aqueous acetone) furnished small, soft, lemon-yellow prismatic needles, m. p. 218–219° (clear at 222°) of the γ -isomer; a mixture with the β -compound had m. p. 200–220° (Found: C, 63.95; H, 3.95; N, 15.0%). From the filtrates a small amount of the β -compound was isolated by means of ethyl acetate.

Fraction (d) (extremely soluble in acetone) was combined with the material remaining in the mother-liquors of fractions (b) and (c), and the whole fractionated from ethyl acetate; some β -isomer was first removed, and the filtrates then deposited δ -nitro-4-phenyl-3-methylcinnoline N-oxide, which separated in rosettes of small colourless needles, m. p. 198–199° (180–188° when mixed with the γ -compound) (Found: C, 64.0; H, 3.8; N, 15.25%).

Owing to the difficulty of separation, it was not possible to assess the relative proportions in which the isomers were present in the crude nitration product.

Reduction of 4-Substituted Cinnolines.—(a) A solution of 4-phenyl-3-methylcinnoline (2.5 g.) in

alcohol (100 c.c.) was reduced, and the product isolated, as described in (b). The oil obtained by evaporation of the washed and dried extract was treated (in alcohol; 20 c.c.) with picric acid (2.5 g.), and the mixture of picrates (3.75 g.) fractionated from alcohol. The least soluble fraction was 4-phenyl-3-methylcinnoline picrate (1 g.), which formed small brown leaflets or prismatic needles, m. p. 179—181° alone and mixed with an authentic specimen (m. p. 180—181°) (Found: C, 55.85; H, 3.4; N, 15.6. $C_{11}H_{13}N_2C_6H_5O_7$ requires C, 56.1; H, 3.35; N, 15.6%). The filtrates yielded 3-phenyl-2-methylindole picrate (2.5 g.) as purple needles with a green reflex, m. p. 139—141° (Found: C, 58.0; H, 3.85; N, 13.15. Calc. for $C_{11}H_{13}N_2C_6H_5O_7$: C, 57.8; H, 3.7; N, 12.8%) (Trenkler, *Annalen*, 1888, 248, 106, gives m. p. 141—142°).

(b) 4-*p*-Anisyl-3-methylcinnoline (0.01 mol.) in alcohol (150 c.c.) was refluxed and treated with sodium (10 g., ca. 20 pieces) during $\frac{1}{2}$ hour, added through a trap to avoid loss of the evolved gases, which were led *via* the reflux condenser into two flasks containing *N*/5-hydrochloric acid. After the sodium had dissolved the system was swept out with a slow stream of nitrogen for $\frac{1}{2}$ hour; the mixture was then poured into water (400 c.c.) and extracted with ether. [This procedure was followed in all the experiments described below, and in general at least two runs were carried out for each compound; individual results, of which the ammonia figures on p. 1650 are mean values, agreed within 5—6%. In experiments with cinnolines containing a *p*-hydroxyphenyl group, the alkaline solution from the ether-extraction was acidified to pH 8 with acetic acid and again extracted (such extracts are referred to as "pH 8 fractions"). Separation of the reaction products was only qualitative.] The extract yielded 3-*p*-anisyl-2-methylindole as sole crystalline product, separating from benzene-ligroin (b. p. 40—60°) or from aqueous alcohol in colourless needles, m. p. 127—128° (Found: C, 80.8; H, 6.25. $C_{11}H_{13}ON$ requires C, 81.0; H, 6.3%). The picrate, prepared in benzene solution, formed almost black, lustrous needles, m. p. 128—130° (Found: C, 56.65; H, 3.95; N, 12.3. $C_{11}H_{13}ON.C_6H_5O_7N_3$ requires C, 56.65; H, 3.85; N, 12.0%).

(c) 4-*p*-Hydroxyphenyl-3-methylcinnoline gave an aqueous alkaline solution which, after ether-extraction, deposited a solid which did not melt at 330° (evidently the sodium salt of the cinnoline). The ether-extract yielded 3-*p*-hydroxyphenyl-2-methylindole, which crystallised from benzene in almost colourless prisms, m. p. 135—136° (Found: C, 80.2; H, 5.8; N, 7.0. $C_{11}H_{13}ON$ requires C, 80.7; H, 5.9; N, 6.3%), soluble in cold 2*N*-sodium hydroxide, but not in aqueous ammonia or sodium carbonate. The pH 8 fraction was an oil which (in alcohol) gave unreduced cinnoline, m. p. 238—241° (identified by mixed m. p.).

(d) 3-Phenyl-4-*p*-anisylcinnoline gave a crystalline mixture, m. p. 47—70°. Digestion with ether afforded, with heavy losses, a less soluble fraction, m. p. 132—145° (unchanged by recrystallisation from alcohol), which was not further purified.

(e) The extract of the alkaline mixture from the reduction of 3-phenyl-4-*p*-hydroxyphenylcinnoline and also the pH 8 fraction yielded unchanged material, m. p. and mixed m. p. 283—286°, but unidentified products were also present.

(f) 4-*p*-Anisylcinnoline gave a glassy resin which could not be obtained crystalline or converted into a crystalline picrate or hydrochloride.

(g) By extraction of the alkaline solution, 4-*p*-hydroxyphenylcinnoline yielded 3-*p*-hydroxyphenylindole, which crystallised from benzene in small golden prismatic needles, m. p. 152—154° (Found: C, 79.75; H, 5.2; N, 6.8. $C_{11}H_{11}ON$ requires C, 80.35; H, 5.3; N, 6.7%); the solubility of this substance in alkalis was similar to that of its homologue described in (c). The pH 8 fraction was an oily solid from which 4-*p*-hydroxyphenylcinnoline was isolated (m. p. 234—235° alone and mixed with an authentic specimen).

(h) The ether extract from the reduction of 4-methylcinnoline gave an oily solid which on recrystallisation from ligroin (b. p. 40—60°) yielded skatole, m. p. 95.5—96.5° (Found: C, 82.0; H, 7.5; N, 10.6. Calc. for C_9H_9N : C, 82.4; H, 6.9; N, 10.7%). The ligroin filtrates were evaporated, and the residue was treated with picric acid in benzene and the resultant solid recrystallised from alcohol, from which 4-methylcinnoline picrate separated in dark green prismatic needles, m. p. 177—178° alone and mixed with an authentic specimen (this vol., p. 811).

(i) In the case of 7-chloro-4-methylcinnoline, skatole separated directly when the mixture was poured into water, and was collected and identified (m. p. 96.5° alone and when mixed with the sample described above). The picrate, soft red needles from alcohol, had m. p. 177—178° (Marion and Ashford, *Canad. J. Res.*, 1945, 23, B, 26, give m. p. 182°) (Found: C, 50.0; H, 3.4. Calc. for $C_9H_8N.C_6H_5O_7N_3$: C, 50.0; H, 3.4%). It turned yellow on standing in the air, and after 3 days had m. p. 225—230°. The aqueous filtrate from the skatole was extracted with ether, yielding an oil from which 4-methylcinnoline was isolated as picrate (m. p. 170—173°, not depressed when mixed with authentic material).

(j) Ether-extraction of the product from 6-chloro-4-methylcinnoline gave an oil, from which skatole (m. p. 95—96°) was isolated by means of ligroin (b. p. 40—60°) (picrate, m. p. 172—174°, not depressed by admixture with the specimen described above). The first ligroin filtrate was evaporated and the residue converted into the picrate, which was digested with alcohol; the green solid so obtained had m. p. 185—187° (6-chloro-4-methylcinnoline picrate has m. p. 154—156°; this vol., p. 811) and gave marked depressions in m. p. when mixed with the picrates of skatole and 4-methylcinnoline.

We are indebted to Imperial Chemical Industries Limited (Dyestuffs Division) for support of this work, and to the Council of the Durham Colleges for a grant from the Research Fund during the early stages.

329. Cinnolines. Part XV. The Alkaline Decomposition of Some Quaternary Salts of 4-Substituted Cinnolines.

By J. C. E. SIMPSON.

The reaction which occurs when 4-substituted alkylcinnolinium salts are treated with alkali depends markedly on the nature of the 4-substituent. 4-*p*-Hydroxyphenylcinnoline ethiodide gives, as major products, acetaldehyde and the parent base, and the reaction shows significant qualitative similarities to that previously studied (McIlwain, *J.*, 1937, 1704) with alkylphenazonium salts. On the other hand, retention of the *N*-alkyl group is observed with 6-chloro-4-aminocinnoline methiodide, which yields mainly ammonia and 6-chloro-1-methyl-4-cinnolone.

THE experiments described in this paper were undertaken with the object of locating the basic centre of 4-substituted cinnolines, the scheme envisaged being the preparation of quaternary salts of such compounds and study of their decomposition reactions in the hope that the point of quaternary salt formation, and hence the basic centre, might thus be disclosed. Combination of 4-phenyl-3-methyl-, 4-*p*-hydroxyphenyl-, and 3-phenyl-4-*p*-hydroxyphenylcinnoline with ethyl iodide proceeded readily, giving the corresponding ethiodides in reasonably high yields. Preliminary experiments showed that 4-*p*-hydroxyphenylcinnoline ethiodide (I; R = H) was very readily decomposed under mild alkaline conditions; an intense crimson coloration was first produced, and the parent cinnoline was isolated from the reaction mixture. Although this result was disappointing from the point of view of the objective mentioned, the reaction seemed of sufficient interest to merit further study. It was then found that the decomposition was not alkali-catalysed, that it could be effected by cold or hot aqueous sodium hydroxide or carbonate and by hot ammonium hydroxide, and that acetaldehyde was a major product of the reaction.

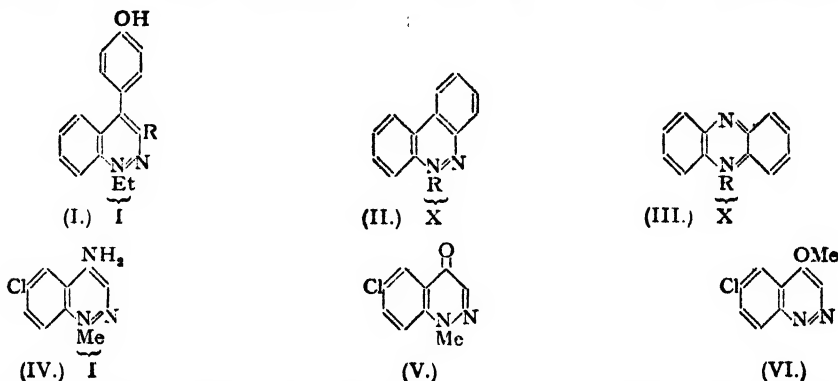

The decomposition of 3-phenyl-4-*p*-hydroxyphenylcinnoline ethiodide (I; R = Ph) was not examined in detail, but probably proceeds analogously, as the parent base was readily isolated, and the smell of acetaldehyde was noticeable during the reaction. It is possible that quaternary salts of 3:4-benzocinnoline (II) decompose in the same way, as Ullmann and Dieterle (*Ber.*, 1904, 37, 23) noted that the parent base was regenerated by treatment of such salts with alkali, but did not investigate the reaction further. This type of reaction is strongly reminiscent of that shown by phenazonium salts (III) in alkaline solution; the regeneration of the parent base from such salts has been observed by various workers, and a more recent study of this reaction by McIlwain (*J.*, 1937, 1704) has shown that it takes the course $2 \text{ BMc} \cdot \text{OH} \longrightarrow \text{B} + \text{BHMc} + \text{CH}_2\text{O} + \text{H}_2\text{O}$.

There is thus a striking parallel between the decomposition of alkylphenazonium salts and that of certain alkylcinnolinium halides. However, further examination of the decomposition of (I; R = H) disclosed that the yield both of 4-arylcinnoline and of acetaldehyde was 70–75 mols.% (based on quaternary salt) and thus indicated that the relationship between the reactions is merely qualitative. The extent to which the 25% of unrecovered cinnoline functions as hydrogen acceptor is unknown; identification of hydrogen as a product of reaction was not attempted, and the non-volatile residue, after removal of 4-*p*-hydroxyphenylcinnoline, was an oil. The properties of the latter suggested instability—for example, the oil was soluble in acetone giving a brilliant blue solution, the colour of which faded completely after some hours' exposure to the air; this behaviour, also, is reminiscent of that shown by alkylphenazonium salts, which give rise to free radicals (McIlwain, *loc. cit.*). Qualitative similarity between the reactions of the two series of salts was further suggested by the observation that, under suitable conditions, the decomposition of the cinnolinium salt is accompanied by nuclear iodination with formation of *x*-iodo-4-*p*-hydroxyphenylcinnoline; this is almost certainly a case of anionoid substitution, which is a characteristic feature of the decomposition of phenazonium salts (McIlwain, *loc. cit.*).

The resemblance between the decompositions of cinnolinium and of phenazonium salts is not unexpected in view of the vinylogous relationship existing between the location of the nitrogen atoms in the two heterocyclic systems. The reaction may not, however, be characteristic of all 4-arylcinnolinium compounds; for example, 4-phenyl-3-methylcinnoline ethiodide did not show this behaviour, and the following observations clearly indicate that the nature of the 4-substituent profoundly influences the reaction.

From 6-chloro-4-aminocinnoline (Part XVII, in the press) was obtained an excellent yield of the methiodide (IV), which on treatment with a large excess of alkali hydroxide at room

temperature was converted into the methohydroxide (or pseudo-base). This substance was stable at room temperature, but in hot alkaline solution decomposed into ammonia and 6-chloro-1-

methyl-4-cinnolone (V). The structure of (V) (the major product of the reaction) follows from its identity with the product of the action of methyl sulphate on 6-chloro-4-hydroxycinnoline, whereas treatment of 4:6-dichlorocinnoline with sodium methoxide furnished the isomeric 6-chloro-4-methoxycinnoline (VI). The position of quaternary salt formation in 6-chloro-4-aminocinnoline is thus established as N_1 ; this is, therefore, the basic centre of this substance, and probably of other Bz-substituted 4-aminocinnolines (Part XVII) also.

This evidence, taken in conjunction with the properties of 4-methylcinnolines described in Part XII (*J.*, 1947, 808), lends strong support to the suggestion (*loc. cit.*) that the basic nitrogen of all 4-substituted cinnolines is N_1 ; the alternative thesis, namely that the centre of basicity could be shifted from N_1 to N_2 by the introduction of suitable 4-substituents, now becomes a more remote contingency. It should be noted, however, that formal proof of this point is still lacking for 4-hydroxycinnolines; the fact that in these substances alkylation occurs at N_1 is irrelevant, because *N*-alkylation of any hydroxylated nitrogenous heterocyclic ring involves triad or pentad prototropy, irrespective of basicity. It happens that in 4-hydroxycinnolines N_1 functions in both capacities, but this need not always be so, and our experience with certain quinazoline derivatives (Morley and Simpson, in the press) has in fact demonstrated that in these compounds the positions of quaternary salt formation and *N*-alkylation are probably not identical.

The decomposition of (IV) also gave rise to small amounts of two other substances of unknown structure. One of these was a neutral compound (substance X), isomeric with (V) and (VI), which could not be hydrolysed under mild conditions; the formation of this compound was apparently independent of the pH of the medium provided alkalinity was maintained. The other compound was an iodide, m. p. 238°, isolated from faintly acid solution.

EXPERIMENTAL.

(Melting points are uncorrected.)

4-Phenyl-3-methylcinnoline Ethiodide.—A solution of the cinnoline (3 g.) in alcohol (15 c.c.) and ethyl iodide (7.5 c.c.) was refluxed for 4 hours. Concentration and cautious addition of ether precipitated the crude ethiodide, which separated from alcohol in soft, light-red needles, m. p. 206–207° [Found: C, 53.85; H, 4.8; I (mean of several inconsistent values), 35.3. $C_{17}H_{11}N_2I$ requires C, 54.25; H, 4.55; I, 33.75%]. On the small scale, decomposition of the salt with aqueous sodium hydroxide at room temperature gave an amorphous basic solid from which no 4-phenyl-3-methylcinnoline could be isolated, and which did not give a crystalline picrate.

3-Phenyl-4-p-hydroxyphenylcinnoline Ethiodides.—A suspension of the cinnoline (2.5 g.) in alcohol (30 c.c.) and ethyl iodide (10 c.c.) was refluxed for 7 hours, a clear dark-coloured solution being gradually formed. On concentration, a mixture (2.35 g.) separated, from which substantially pure monoethiodide (0.9 g.) was obtained by recrystallisation from alcohol; the pure compound formed clusters of small orange leaflets, m. p. 227–228° (decomp.) (Found: C, 58.15; H, 4.45; I, 26.35. $C_{22}H_{19}ON_2I$ requires C, 58.15; H, 4.2; I, 28.0%). It (400 mg.) was decomposed by hot *N*-sodium hydroxide (10 c.c.) (an intensely purple-crimson solution was produced) with regeneration of the original cinnoline (130 mg., m. p. 283–285°, mixed m. p. 284–286°); no search for other products was made, but the odour of acetaldehyde was observed during the decomposition [cf. the decomposition of 4-*p*-hydroxyphenylcinnoline ethiodide (*q.v.*)]. The salt gave an intense crimson solution in concentrated sulphuric acid; on dilution the colour faded and a precipitate was formed.

The filtrate from the crude monoethiodide (from another experiment) was concentrated further; the resultant solid, after several crystallisations from alcohol, formed deep ruby-red blades, m. p. 216–217°

(190—195° when mixed with the monoethiodide), and from analysis appeared to consist principally of a diethiodide (Found: C, 44.7; H, 3.25; I, 37.5. $C_{14}H_{11}ON_2I_2$ requires C, 47.2; H, 4.0; I, 41.6%).

Addition of a drop of piperidine to an alcoholic solution of the mixed ethiodides gave an intense green colour, becoming deep blue-green on dilution. Addition of acid to this solution destroyed the colour, which was restored (purple) by ammonia or sodium carbonate with precipitation at an intermediate stage of an amphoteric solid.

Preparation and Alkaline Decomposition of 4-p-Hydroxyphenylcinnoline Ethiodide.—The cinnoline (10 g.), alcohol (200 c.c.), and ethyl iodide (80 c.c.) were refluxed for 4 hours. The ethiodide, obtained by concentration, crystallised from alcohol in scarlet prisms, m. p. 237—239° (Found: C, 51.15; H, 4.15. $C_{14}H_{11}ON_2I$ requires C, 50.8; H, 4.0%; satisfactory iodine figures could not be obtained); yield of nearly pure compound, 13 g. The salt gave a deep crimson solution in concentrated sulphuric acid, becoming yellow on dilution. Addition of piperidine to an alcoholic solution produced a very intense purple colour, discharged by acid and restored by ammonia or sodium carbonate solution.

The following alkaline decompositions of the salt were carried out.

(a) A solution of the salt (1 g.) in warm water (80 c.c.) was treated with 2N-sodium carbonate (20 c.c.) and heated at 90—95°; nitrogen was bubbled through the liquid, and the issuing gases were passed into a solution of 2:4-dinitrophenylhydrazine (0.6 g.) in 10% sulphuric acid (66 c.c., v/v). After 1 hour the precipitated hydrazone was collected (0.43 g., m. p. 143—144°) and recrystallised from alcohol, yielding flat yellow needles, m. p. 166.5—167.5° alone and mixed with authentic acetaldehyde 2:4-dinitrophenylhydrazone. The alkaline solution in the reaction flask was acidified with acetic acid, giving almost pure 4-p-hydroxyphenylcinnoline (0.45 g.), m. p. 229—231°, and 232—233° (alone and in admixture with authentic material) after crystallisation from alcohol.

(b) An experiment carried out as in (a) except that the sodium carbonate was replaced by 2N-sodium hydroxide (20 c.c.) gave 4-p-hydroxyphenylcinnoline in identical yield and purity, but only 0.15 g. of crude aldehyde dinitrophenylhydrazone (m. p. 129—135°). From this, a small amount of acetaldehyde 2:4-dinitrophenylhydrazone, m. p. 161—163°, was obtained by repeated crystallisation from alcohol. Apparently other aldehydes had been present (probably formed by self-condensation of the acetaldehyde), but these were not identified. The identity of the cinnoline obtained in this and the preceding experiment was confirmed by acetylating the combined crops; 4-p-acetoxyphenylcinnoline (preceding paper), m. p. and mixed m. p. 127.5—128.5°, was thus obtained.

(c) A solution of the salt (2 g.) in water (240 c.c.) and 2N-sodium carbonate (40 c.c.) was left for 4 months in an uncorked flask at laboratory temperature. The solid which had separated was collected and washed with water until the washings were colourless; 0.95 g., m. p. 237—241°. As it could not be purified by crystallisation, the whole was acetylated (boiling acetic anhydride) and freed from solvent in an evacuated desiccator. The residue was repeatedly crystallised from benzene-ligroin (b. p. 60—80°), yielding α -iodo-4-p-acetoxyphenylcinnoline as stout, pale yellow polyhedra, m. p. 158—160° (Found: C, 50.2; H, 2.9; N, 7.9; I, 33.55. $C_{14}H_{11}O_2N_2I$ requires C, 49.2; H, 2.85; N, 7.2; I, 32.6%). From a small-scale experiment in which the alkaline solution had stood for only 10 weeks a mixture was isolated which could not be purified by direct crystallisation but which (m. p. 243—244°) contained iodocinnoline (Found: I, 18.35. Calc. for $C_{14}H_9ON_2I$: I, 36.5%); pure 4-p-acetoxyphenylcinnoline was readily isolated by acetylation of the more soluble material.

(d) In other experiments in which sodium and ammonium hydroxide were used, the reaction mixtures were extracted with ether before acidification; small amounts of a brown oil were thus obtained, which was easily soluble in acetone giving a brilliant and very intense purple solution, the colour of which faded perceptibly during 2 hours' exposure to the air, and completely on standing overnight.

(e) A solution of the salt (0.5 g.) in water (45 c.c.) and 4N-ammonia (5 c.c.) was left at laboratory temperature for 10 weeks in an open flask. A sticky solid separated during this time, from which unchanged quaternary salt was isolated (by extraction with hot water) as the only identifiable product.

6-Chloro-4-methoxycinnoline.—A solution of 4:6-dichlorocinnoline (2 g.; this vol., p. 917) and sodium methoxide (0.8 g.) in methyl alcohol (50 c.c.) was refluxed for 20 minutes, cooled, acidified with acetic acid, and diluted with water. The precipitate was filtered off, washed, and recrystallised from methyl alcohol, from which 6-chloro-4-methoxycinnoline (1.5 g.) separated in colourless narrow blades, m. p. 169.5—170° (Found: C, 55.6; H, 3.9; N, 13.9. $C_9H_7ON_2Cl$ requires C, 55.5; H, 3.6; N, 14.4%).

6-Chloro-1-methyl-4-cinnolone.—Methyl sulphate (2 c.c.) was added to a slightly warm solution of 6-chloro-4-hydroxycinnoline (2 g.; *J.*, 1945, 520) in aqueous potassium hydroxide (20%, 40 c.c.). The mixture was heated on the steam-bath, separation of the product (2 g., m. p. 188—200°) occurring almost immediately. After several crystallisations from water containing a little 2N-hydrochloric acid, and finally from alcohol, 6-chloro-1-methyl-4-cinnolone separated in stout, pale yellow, brittle needles, m. p. 221—222° after previous shrinking (Found: C, 55.85; H, 4.0; N, 14.2. $C_9H_7ON_2Cl$ requires C, 55.5; H, 3.6; N, 14.4%). Although the free base separates from dilute hydrochloric acid, it is distinctly more soluble therein than in water alone (from which it forms long, silky needles).

Preparation and Alkaline Decomposition of 6-Chloro-4-aminocinnoline Methiodide.—Prepared from 6-chloro-4-aminocinnoline (Part XVII, in the press) (8 g.), alcohol (100 c.c.), and methyl iodide (20 c.c.) (3½ hours under reflux), 6-chloro-4-aminocinnoline methiodide (crude yield, 12.1 g.) crystallised from hot water in long, saffron-coloured needles, m. p. 225—226° (decomp.) (Found: C, 32.35; H, 3.2; N, 12.5. $C_9H_7N_3ClI \cdot 0.5H_2O$ requires C, 32.7; H, 3.05; N, 12.7%. Halogen determinations were unsatisfactory). The following procedure was the outcome of several preliminary experiments.

A solution of the salt (4 g.) in water (160 c.c.) was treated with 2N-sodium hydroxide (100 c.c.) and left at laboratory temperature. The dark oil which soon separated from the green solution changed overnight to a mass of soft, almost colourless needles, which (1.5 g.) were filtered off (filtrate A) and, without purification (the substance was unstable and could not be recrystallised), dissolved in 50% aqueous acetic acid (10 c.c.) (solution B). One half of this solution was brought to pH 9 with sodium hydroxide and boiled gently for ½ hour; a little ammonia was evolved. The solution was diluted

somewhat with water and filtered hot (charcoal); a solid separated on cooling, which on recrystallisation from water yielded substance X in long, colourless needles, m. p. 162–163°, which gave a positive Beilstein halogen test (Found: C, 55.9; H, 3.7; N, 14.4, 14.7. $C_9H_7ON_2Cl$ requires C, 55.5; H, 3.6; N, 14.4%). This substance was less soluble in water than 6-chloro-1-methyl-4-cinnolone, and crystallised well from benzene. It gave a marked depression in melting point when mixed with 6-chloro-4-methoxycinnoline. It showed no basic or acidic properties, and was unaffected by short boiling with dilute hydrochloric acid or sodium hydroxide. The first filtrate from substance X was made alkaline to thymolphthalein (sodium hydroxide) and boiled; ammonia was again evolved, and recrystallisation (water; charcoal) of the solid which separated from the hot solution yielded 6-chloro-1-methyl-4-cinnolone, m. p. and mixed m. p. 220–221°. The other half of solution B was made strongly alkaline with sodium hydroxide and boiled; substance X and 6-chloro-1-methyl-4-cinnolone were separated (by the use of dilute hydrochloric acid) and identified (m. p. and mixed m. p.).

Filtrate A was divided into 2 parts. One was decomposed at pH 11 by boiling, and yielded ammonia, 6-chloro-1-methyl-4-cinnolone, and substance X. The other part was brought to pH 6 with acetic acid, boiled for 20 minutes, and concentrated on the steam-bath to 2/3 volume. The mixture which separated gave 6-chloro-1-methyl-4-cinnolone as the least soluble component, and the early filtrates from this compound contained an iodide; this salt, after several crystallisations from alcohol, formed yellow rosettes of small needles, m. p. 237–238° (Found: C, 43.05; H, 3.95; N, 12.6%).

Similar results to the above were obtained when the original treatment of the quaternary salt with sodium hydroxide was performed under nitrogen.

The author is indebted to Imperial Chemical Industries Limited (Dyestuffs Division) for various facilities, and to the Council of the Durham Colleges for a grant from the Research Fund during the early part of this investigation.

330. Miscellaneous Thiazoles.

EDWARD B. KNOTT.

Derivatives of 4-o-carboxyphenylthiazole (I) and 4-phenylthiazole-5-carboxylic acid (II) prepared by standard methods could not be cyclised to indonothiazoles (III). Phenylthiobiuret and α -halogeno-ketones react together to give *azamethin* bases (IV). A few new thiazyl sulphides have been prepared. 2-Chloroacetyl furan and 2-bromoacetyl furan have been obtained crystalline and converted into derivatives of 4-(2'-furyl)thiazole (VI). 2-Chloroacetylpyrrole condenses normally with thiourea and normally with thioacetamide in the presence of alkali to give derivatives of 4-(2-pyrrolyl)thiazole (VII), but abnormally with alkyl dithiocarbamates to give di-(2-pyrrolylmethyl) sulphide (VIII).

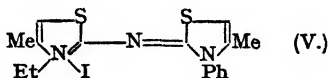

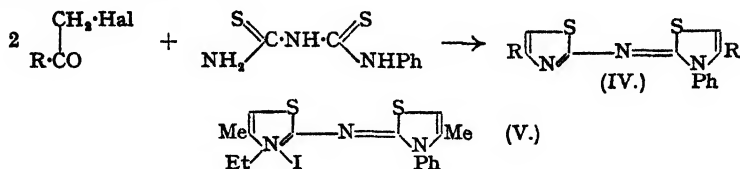

THE formation of polycarbocyclic thiazoles by intramolecular ring closure of 4-arylthiazole-5-acetic acids has been reported recently (Knott, J., 1945, 455). In attempts to prepare indonothiazoles (III) by analogous methods two types of intermediate were required, namely, a 4-o-carboxyphenylthiazole (I) and a 4-phenylthiazole-5-carboxylic acid (II; $R' = H$). (I) was readily prepared from o-carboxyphenacyl bromide and (II; $R' = Et$) from ethyl α -bromobenzoylacetate or the chloro-analogue (Hirst, Macbeth, and Traill, *Proc. Roy. Irish Acad.*, 1925, 37B, 47). Hydrolysis of (II; $R = Me$, $R' = Et$) gave the required acid, but where $R = NH_2$ simultaneous loss of carbon dioxide gave 2-amino-4-phenylthiazole. Ethyl α -bromobenzoylacetate condensed with ethyl and isopropylthioncarbamates to give ethyl 2-hydroxy-4-phenylthiazole-5-carboxylate (II; $R = OH$, $R' = Et$); the simultaneous loss of the alkyl group was also observed by Hantzsch and Hubacher (*Annalen*, 1890, 259, 250) whilst employing chloroacetone.

All cyclisation experiments on the acids or esters were unsuccessful.

The condensation of dithiomalonamides with α -halogeno-ketones has been described by Lehr, Guex, and Erlenmeyer (*Helv. Chim. Acta*, 1944, 27, 972) who thus obtained dithiazolylmethanes. Some time ago an analogous reaction was applied to phenylthiobiuret which condensed very readily with chloroacetone and phenacyl bromide to give *azamethin* bases (IV). Where $R = Me$ (IV) formed an *ethiodide* which is [2-(4-methyl-3-ethylthiazole)][2-(3-phenyl-

4-methylthiazole]azamethincyanine iodide (V). This pale yellow dye does not sensitise a photographic silver chloride emulsion.

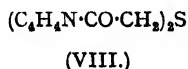

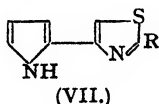

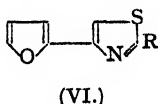

Using the method of Buchman, Reims, and Sargent (*J. Org. Chem.*, 1941, 6, 764) for the direct formation of 2-alkylthiothiazoles by the condensation of chloroacetone and methyl dithiocarbamate, 2-alkylthio-4-phenylthiazoles and 2-benzylthio-4-phenylthiazole have been prepared.

As intermediates for photographic sensitising dyes, 4-(2'-furyl)-* and 4-(2'-pyrryl)-thiazoles containing a reactive substituent in the 2-position were required.

2-Chloroacetylfuran, one of the intermediates for the preparation of the above thiazoles, has been obtained as an oil by Gilman and Burtner (*J. Amer. Chem. Soc.*, 1935, 57, 911), and by Burger and Harnest (*ibid.*, 1943, 65, 2382); it has now been found to crystallise readily at room temperature as did also 2-bromoacetylfuran. 2-Chloroacetylpyrrole, the second required intermediate, was obtained in 20% yield from pyrrole and chloromethyl cyanide by Blicke, Faust, Gearien, and Warzynski (*J. Amer. Chem. Soc.*, 1943, 65, 2465). Using this method with slight variations, a 35% yield was obtained.

The halogeno-acetylfuran condensed normally with thiourea, thioacetamide, and methyl dithiocarbamate to give the 2-amino-, 2-methyl-, and 2-methylthio-derivatives of 4-(2'-furyl)-thiazole (VI; R = NH₂, Me, SMe).

2-Chloroacetylpyrrole condensed normally with thiourea giving the hydrochloride of 2-amino-4-(2'-pyreryl)thiazole (VII; R = NH₂) as sole product. With thioacetamide, however, condensation in alcohol gave a deep red solution, and the resultant product was difficult to purify. The formation of dye was prevented, however, in the presence of alkali carbonate and the main reaction product was the expected 4-(2'-pyreryl)-2-methylthiazole (VII; R = Me) although an appreciable amount of a crystalline solid was obtained, which was not volatile in steam. With methyl dithiocarbamate the chloro-ketone gave chiefly a purple dye in the absence of alkali. The addition of alkali carbonate again prevented dye formation, but the product obtained was identical with the by-product obtained in the thioacetamide condensation. It is di-(2-pyrroyl-methyl) sulphide (VIII). The same product was obtained from the chloro-ketone and ethyl dithiocarbamate, ammonium dithiocarbamate, or sodium sulphide. The mechanism of this abnormal reaction is probably analogous to the formation of substituted diquinolyl sulphides from chloroquinolines and thiourea (Rosenhauer, Hoffmann, and Heuser, *Ber.*, 1929, 62, 2730; Renfrew, *J. Amer. Chem. Soc.*, 1946, 68, 1433) and of other diheterocyclyl sulphides from heterocyclyl chlorides and thiourea (Surrey and Lindwall, *J. Amer. Chem. Soc.*, 1940, 62, 1697; Watt, *J. Org. Chem.*, 1939, 4, 436).

EXPERIMENTAL

(Analyses are by Drs. Weiler and Strauss, Oxford: m. ps. are not corrected.)

4-o-Carboxyphenyl-2-methylthiazole (I; R = Me). *o*-Carboxyphenacyl bromide (1.22 g.; 0.005 mol.) (Gabriel and Michael, *Ber.*, 1877, 10, 1551) and thioacetamide (0.375 g.; 0.005 mol.) gave the hydrobromide on refluxing together for 15 minutes in isopropyl alcohol (2.5 c.c.). The base, m. p. 143–147°, formed colourless needles from aqueous methyl alcohol (Found: S, 14.5. $C_{11}H_9O_2NS$ requires S, 14.65%). **2-Amino-4-o-carboxyphenylthiazole** (I; R = NH_2), obtained similarly from thiourea (0.38 g.), formed soft needles, m. p. 174° (decomp.), from alcohol. The needles contained solvent of crystallisation removed by drying at 115°/20 mm. (Found: S, 14.7. $C_{11}H_9O_2NS$ requires S, 14.56%).

4-Phenyl-2-methylthiazole-5-carboxylic Acid (II; R = Me, R' = H). Thioacetamide (0.75 g.; 0.01 mol.), ethyl α -bromobenzoylacetate (2.6 g.; 0.01 mol.), and isopropyl alcohol (10 c.c.) were refluxed

* Since this paper was written, B.P. 571,077 has appeared describing the condensation of 2-bromoacetyl-furan (obtained by bromination of 2-acetyl-furan) with thioacetamide to give 4-(2'-furyl)-2-methyl-thiazole.

for 15 minutes, diluted with aqueous sodium carbonate, and the precipitated oil taken up in ether which was dried, the ether then being removed. The oil could not be crystallised. It was dissolved in alcohol (5 c.c.) and shaken with 10% aqueous hydroxide (2 c.c.), then allowed to stand for 3 hours. The acid obtained on acidification formed pink tablets, m. p. 216° (decomp.), from alcohol (Found: S, 14.45. $C_{11}H_9O_2NS$ requires S, 14.65%).

Ethyl 2-Amino-4-phenylthiazole-5-carboxylate.—This, obtained similarly from ethyl α -bromobenzoylacetate and thiourea, formed thick, pale yellow needles, m. p. 173° (Hirst *et al.*, *loc. cit.*, give m. p. 173°) from methyl alcohol (Found: S, 12.85. Calc. for $C_{12}H_{13}O_2N_2S$: S, 12.9%). The ester (1.0 g.) was dissolved in hot alcohol (20 c.c.), 10% aqueous sodium hydroxide (2 c.c.) was added, and after 30 minutes at 50° the solution was neutralised with dilute acetic acid, giving colourless needles of 2-amino-4-phenylthiazole, m. p. 151°, not depressed on admixture with authentic specimen obtained from phenacyl bromide and thiourea (Found: S, 17.95. Calc. for $C_8H_7N_2S$: S, 18.2%).

Ethyl 2-Hydroxy-4-phenylthiazole-5-carboxylate (II; R = OH, R' = Et).—Ethyl α -bromobenzoylacetate (2.6 g.; 0.01 mol.), ethyl thioncarbamate (1.05 g.; 0.01 mol.) or isopropyl thioncarbamate (1.19 g.), and isopropyl alcohol (5 c.c.) were boiled together for a few minutes. The liquor clouded and deposited pale yellow needles, which then formed colourless needles from alcohol, m. p. 202°, soluble in ammonia (Found: S, 12.9. $C_{13}H_{11}O_3NS$ requires S, 12.85%).

Azamethin[2-(4-phenylthiazole)][2-(3:4-diphenyl-2:3-dihydrothiazole)] (IV; R = Ph).—Phenacyl bromide (0.4 g.; 0.002 mol.) was added to a hot solution of phenyldithiobiuret (0.215 g.; 0.01 mol.) in absolute ethyl alcohol (10 c.c.) and refluxed for 15 minutes. To this solution was then added anhydrous sodium carbonate (1.1 g.) and the mixture refluxed for a further 15 minutes. Addition of water (100 c.c.) precipitated the base as a solid which formed colourless needles (0.4 g.), m. p. 228—230°, from benzene-light petroleum (Found: C, 70.7; H, 4.1; N, 9.85. $C_{24}H_{17}N_4S_2$ requires C, 70.0; H, 4.15; N, 10.2%). The dihydrobromide was obtained if the carbonate addition was omitted and the mixture concentrated after 1 hour. From isopropyl alcohol it formed yellow prisms, m. p. 152° (Found: HBr, 28.25. $C_{24}H_{17}N_4S_2 \cdot 2HBr$ requires HBr, 28.25%).

Azamethin[2-(4-methylthiazole)][2-(3-phenyl-4-methyl-2:3-dihydrothiazole)] (IV; R = Me).—By proceeding as above but using phenyldithiobiuret (1.07 g.) and chloroacetone (0.92 g.), the base was obtained as faintly yellow needles, m. p. 170—171°, from alcohol (Found: S, 22.25. $C_{14}H_{13}N_2S_2$ requires S, 22.35%).

[2-(4-Methyl-3-ethylthiazole)][2-(3-phenyl-4-methylthiazole)]azamethincyanine Iodide (V).—The base (IV; R = Me) (1 g.) and ethyl iodide (1 c.c.) were heated for 8 hours in a sealed tube on the steam-bath. From methanol the ethiodide formed yellow needles, m. p. 190—192° (Found: S, 14.7. $C_{15}H_{16}N_2IS_2$ requires S, 14.45%).

2-Alkylthio- and 2-Benzylthio-4-phenylthiazoles.—Molar quantities of phenacyl bromide and the dithiocarbamic ester were refluxed for 15 minutes in ethyl alcohol. The hydrobromides were obtained on concentration. 2-Methylthio-4-phenylthiazole was obtained in colourless needles, m. p. 24°, from benzene (Levi, *Gazzetta*, 1931, 61, 719, describes it as an oil) (Found: S, 30.8. Calc. for $C_{10}H_9NS_2$: S, 30.95%). The hydrobromide formed colourless prisms, m. p. 194—196°, from isopropyl alcohol. The crystals contain the solvent, removed at 115° (Found: S, 22.3. $C_{10}H_9NBrS_2$ requires S, 22.25%). 2-Ethylthio-4-phenylthiazole was obtained as a viscous oil, b. p. 300° (partial decomp.) (Found: S, 29.9. $C_{11}H_{11}NS_2$ requires S, 28.3%). The hydrobromide formed colourless needles, m. p. 167—169°, from isopropyl alcohol. The crystals contain solvent removed at 115° (Found: S, 21.35. $C_{11}H_{11}NBrS_2$ requires S, 21.25%). 2-Benzylthio-4-phenylthiazole formed glassy crystals, m. p. 56—57°, from benzene-light petroleum (Found: S, 22.5. $C_{14}H_{13}NS_2$ requires S, 22.65%). Its hydrobromide had m. p. 192°.

2-Halogenoacetylfurans.—The method employed was essentially that of Burger *et al.* (*loc. cit.*). The furoyl chloride was treated with ethereal diazomethane until the powerful lachrymatory action of the chloride could not be detected on removing a spot of the reaction mixture. Dry hydrogen chloride or bromide was used to decompose the diazo-compound. 2-Chloroacetyl furan, b. p. 125°, solidified after distilling twice. From benzene-light petroleum it formed colourless leaflets, m. p. 30.5°, in 86% yield (Found: Cl, 24.25. Calc. for $C_6H_5O_2Cl$: Cl, 24.55%) (Burger *et al.* report b. p. 93—108°; Gilman *et al.* b. p. 127—129°). 2-Bromoacetyl furan, b. p. 126°, formed colourless leaflets, m. p. 34°, from benzene-light petroleum in 87% yield (Found: Br, 42.15. $C_6H_5O_2Br$ requires Br, 42.4%).

2-Amino-4-(2-furyl)thiazole.—Thiourea (0.38 g.; 0.005 mol.) and chloroacetyl furan (0.722 g.; 0.005 mol.) were dissolved in hot ethyl alcohol (5 c.c.), anhydrous sodium carbonate (0.026 g.; 0.025 mol.) was added, and the mixture refluxed for 5 minutes. On addition of water the thiazole separated. From benzene-light petroleum it formed glistening flat needles, m. p. 124.5°, in 95% yield (Found: S, 19.45. $C_7H_7ON_2S$ requires S, 19.3%).

4-(2'-Furyl)-2-methylthiazole.—Thioacetamide (7.5 g.; 0.1 mol.) and 2-bromoacetyl furan (18.9 g.; 0.1 mol.) were covered with ethyl alcohol (20 c.c.) and warmed gently. Heat was suddenly evolved and after cooling, the required hydrobromide separated, the precipitation being completed by addition of ether. It formed pale brown needles, m. p. 194—196°, from methanol-ether in 87% yield (Found: Br, 32.6; S, 12.85. C_8H_9ONBrS requires Br, 32.5; S, 13.05%). The base was obtained as an oil, b. p. 128°, possessing a strong thiazole odour* (Found: S, 19.35. C_8H_9ONS requires S, 19.4%).

2-Methylthio-4-(2'-furyl)thiazole.—Obtained as for the 2-methyl analogue, the hydrobromide (70% yield) formed tiny plates, m. p. 208—210° (decomp.), from ethyl alcohol-ether (Found: Br, 28.9. $C_8H_9ONBrS_2$ requires S, 28.95%). The base was obtained as a heavy oil, b. p. 177°, with an odour like that of mushrooms (Found: S, 32.4. $C_8H_9ONS_2$ requires S, 32.55%).

2-Chloroacetylpyrrole.—The procedure according to Blicke *et al.* (*loc. cit.*) was followed, but the reaction mixture of the ketimine hydrochloride was allowed to stand for 18 hours before filtration, the hydrolysis solution made neutral to Congo-red with sodium acetate before being heated, and the required product extracted from the resin by repeated refluxing with carbon tetrachloride. With these variations, a 36% yield was obtained.

* B.P. 571,077 gives b. p. 120—130° but no analysis.

2-Amino-4-(2'-pyrryl)thiazole.—Obtained like the furyl analogue, the *base* formed creamy needles, m. p. 160°, from hot water (Found: N, 24.9; S, 19.4. $C_8H_7N_2S$ requires N, 24.45; S, 19.4%). The hydrochloride, m. p. 200° (decomp.), formed greenish needles from alcohol.

4-(2'-Pyrryl)-2-methylthiazole.—Thioacetamide (1.5 g.; 0.02 mol.) and 2-chloroacetylpyrrole (2.87 g.; 0.02 mol.) were dissolved in warm ethyl alcohol (10 c.c.) and excess of anhydrous sodium carbonate (1.0 g.) was added. The whole was refluxed for 30 minutes, the flask being shaken well every time a red coloration developed. On dilution with water an oil was precipitated which solidified. The solid (3.2 g.) was subjected to steam distillation giving 2.5 g. of the steam-volatile thiazole, obtained as glassy aggregates, m. p. 94–95°, from methanol (Found: S, 19.85. $C_8H_8N_2S$ requires S, 19.55%). It can also be purified by distillation (b. p. 171°) or by recrystallisation of the crude condensate from methanol. The residue from the steam distillation (0.5 g.) formed colourless needles, m. p. 179°, from acetone.

Di-(2-pyrrolylmethyl) Sulphide.—(a) 2-Chloroacetylpyrrole (1.435 g.; 0.01 mol), and methylthiocarbamate (1.07 g.; 0.01 mol.) or ethyl dithiocarbamate (1.21 g.), were dissolved in warm ethyl alcohol (5 c.c.) and, after the addition of anhydrous sodium carbonate (1.0 g.) to avoid dye formation, the whole was refluxed for 30 minutes. The precipitate obtained on dilution with water gave needles on recrystallisation from alcohol, m. p. 179–180°, which fluoresced yellow in ultra-violet light. They were identical with the by-product from the thioacetamide condensation.

(b) Equimolecular amounts of 2-chloroacetylpyrrole and ammonium dithiocarbamate were refluxed in alcohol for 10 minutes. Ammonium chloride was precipitated. On dilution with water the sulphide was precipitated, m. p. 179°, mixed m. p. with (a) 179°.

(c) 2-Chloroacetylpyrrole (2 mol.) and sodium sulphide (1 mol.) gave the sulphide after being refluxed for 10 minutes in alcohol. The *product* had m. p. 179° and did not depress the m. p. of the specimens obtained under (a) and (b) (Found: C, 58.25; H, 4.8; N, 11.2; S, 12.95. $C_{12}H_{12}O_2N_2S$ requires C, 58.05; H, 4.85; N, 11.3; S, 12.95%).

331. *Attempts to find New Antimalarials. Part XXVI. Further Derivatives of p-Phenanthroline.*

By BRYCE DOUGLAS, REX G. JACOMB, and WILLIAM O. KERMACK.

2-Chloro-*p*-phenanthroline has been prepared by the action of phosphorus oxychloride and pentachloride on (a) 1-methyl-*p*-phenanthrol-2-one (II) and (b) 2-hydroxy-*p*-phenanthroline (I; R = OH). The former was prepared either by the oxidation of *p*-phenanthroline methiodide with alkaline ferricyanide or from 6-amino-1-methylcarbostyryl by Skraup reaction; (I; R = OH) was similarly prepared from 6-aminocarbostyryl. Phosphorus oxychloride reacts with *p*-phenanthroline *N*-oxide to yield 2-chloro-*p*-phenanthroline (I; R = Cl), and with *p*-phenanthroline di-*N*-oxide to yield 2 : 7-dichloro-*p*-phenanthroline, which was independently synthesised by the action of phosphorus oxychloride and pentachloride on 2 : 7-diketo-1 : 8-dimethyl-1 : 2 : 7 : 8-tetrahydro-*p*-phenanthroline (III) obtained by oxidising the methiodide of 1-methyl-*p*-phenanthrol-2-one. Derivatives of *p*-phenanthroline with basic side chains have been prepared by condensation of 2-chloro-*p*-phenanthroline with appropriate amines.

CERTAIN derivatives of *p*-phenanthroline, including a number carrying basic side chains in positions 2 and 4, have been described by Kermack and Weatherhead (*J.*, 1940, 1164). 2-Chloro-*p*-phenanthroline (I; R = Cl) has now been prepared by oxidising the methiodide of *p*-phenanthroline with alkaline ferricyanide to 1-methyl-*p*-phenanthrol-2-one (II) followed by treatment of this with phosphorus oxychloride containing phosphorus pentachloride. That the chlorine atom in this compound is in fact in the 2-position was proved by preparing it from 6-aminocarbostyryl, which by means of a Skraup reaction was converted into 2-hydroxy-*p*-phenanthroline (I; R = OH), and the latter with phosphorus oxychloride and pentachloride readily yielded the same chloro-*p*-phenanthroline as that obtained by the other route. Further confirmation was obtained by an independent synthesis of 1-methyl-*p*-phenanthrol-2-one by means of a Skraup reaction on 6-amino-1-methylcarbostyryl.

An entirely different route for the synthesis of 2-chloro-*p*-phenanthroline has also been explored, similar to that used by Kermack and Tebrich (*J.*, 1945, 375) for the synthesis of 2-chloro-*m*-phenanthroline. When *p*-phenanthroline was treated with approximately 1 mol. of

perbenzoic acid the mono-*N*-oxide, m. p. 232—233°, along with some impure di-*N*-oxide was obtained. The di-*N*-oxide, m. p. 324—325°, was isolated from an experiment in which a larger proportion of perbenzoic acid was used, Evans and Linsker (*J. Amer. Chem. Soc.*, 1946, 68, 403) claim to have formed the di-*N*-oxide by the action of hydrogen peroxide on the base in acetic acid, but their m. p. (308°) is lower than ours. The action of phosphorus oxychloride on the mono-*N*-oxide gave 2-chloro-*p*-phenanthroline as main product; by treating the di-*N*-oxide in a similar way a compound, m. p. 315—316°, was isolated which was shown to be 2 : 7-dichloro-*p*-phenanthroline in the following way. The methiodide of 1-methyl-*p*-phenanthrol-2-one was oxidised with alkaline ferricyanide to 2 : 7-diketo-1 : 8-dimethyl-1 : 2 : 7 : 8-tetrahydro-*p*-phenanthroline which, when heated in a sealed tube at 150° for 24 hours with phosphorus oxychloride and pentachloride, yielded 2 : 7-dichloro-*p*-phenanthroline identical with a compound isolated from the product of the action of phosphorus oxychloride on the di-*N*-oxide of *p*-phenanthroline. An attempt was made to form the dimethiodide of *p*-phenanthroline by treating the base with methyl iodide under a variety of conditions including heating with a large excess of methyl iodide in nitrobenzene in a sealed tube, but the product consisted practically entirely of the monomethiodide.

As expected, 2-chloro-*p*-phenanthroline reacted readily with primary amines to form compounds such as 2-(2-diethylaminoethylamino)-, 2-(3-diethylaminopropylamino)-, and 2-(4-diethylamino-1-methylbutylamino)-*p*-phenanthroline, characterised respectively as trihydrobromide, trihydrobromide, and tris-3 : 5-dinitrobenzoate.

EXPERIMENTAL

p-Phenanthroline Methiodide.—*p*-Phenanthroline (25 g.) was heated under reflux with methyl iodide (100 c.c.) in nitrobenzene (250 c.c.) for 2 hours on a water-bath. Yellow needles of the methiodide separated during the reaction, and on cooling a further amount was deposited; the combined products were dried in a vacuum and recrystallised from water; yield 38 g., m. p. 270—271° (Found: I, 38.7. $C_{13}H_{11}N_2I$ requires I, 39.4%).

1-Methyl-*p*-phenanthrol-2-one.—(a) A mixture of 6-amino-1-methylcarbostyrl (3.9 g.), 69% sulphuric acid (42 g.), 80% arsenic acid (12 g.), and 90% glycerol (7.2 g.) was refluxed in an oil-bath for 2½ hours at 150°. The mixture, after dilution with an equal bulk of water followed by filtration, was made strongly alkaline with 10*N*-sodium hydroxide solution, and the precipitate collected. This brown solid was purified by prolonged extraction with ether (Sohxlet), the ether yielding 2.5 g., long yellow needles of 1-methyl-*p*-phenanthrol-2-one, m. p. 242° (Found: C, 74.2; H, 5.0. $C_{13}H_{10}ON_2$ requires C, 74.3; H, 4.8%).

(b) To a solution of potassium ferricyanide (21.9 g. in 200 c.c. of water) were added alternately small portions of solutions of *p*-phenanthroline methiodide (9 g. in 500 c.c. of water) and sodium hydroxide (4.2 g. in 100 c.c. of water). When the addition of both solutions had been completed, the mixture was set aside for ½ hour and then made strongly alkaline with 10*N*-sodium hydroxide (250 c.c.). The yellow precipitate was collected, dried on a porous plate, and extracted for 3—4 hours with benzene (250 c.c.) under reflux. After filtration, the process was repeated twice. On cooling, the benzene deposited 4.5 g. of a light yellow material, m. p. 245—246°, and on concentration a further 0.6 g. was obtained, m. p. 245—246°, mixed m. p. with 1-methyl-2-*p*-phenanthrolone, prepared as above, 243—244°.

2-Hydroxy-*p*-phenanthroline.—A mixture of 6-aminocarbostyrl (2.6 g.), arsenic acid (3.2 g.), concentrated sulphuric acid (4.4 g.), and glycerol (4.8 g.) was refluxed gently for 5 hours, then diluted with water to about 50 c.c. An inorganic brown solid (0.5 g.) was filtered off, and the filtrate, on neutralization with 10*N*-sodium hydroxide solution, deposited a brown solid which redissolved in excess of sodium hydroxide. The alkaline solution was neutralised with acetic acid and the precipitate which formed was filtered off, yielding 2.7 g. of a brown solid, m. p. 305—310°. Recrystallised several times from ethanol, 2-hydroxy-*p*-phenanthroline formed yellow needles, m. p. 302—303° (Found: C, 66.75; H, 5.0. $C_{12}H_8ON_2 \cdot H_2O$ requires C, 67.3; H, 4.7%).

2-Chloro-*p*-phenanthroline.—(1) From 2-hydroxy-*p*-phenanthroline. A mixture of 2-hydroxy-*p*-phenanthroline (1 g.), phosphorus pentachloride (1 g.), and phosphorus oxychloride (10 c.c.) was refluxed for 32 hours in an oil-bath, almost complete solution then having taken place. The excess of oxychloride was removed by distillation in a vacuum, and the resulting mass treated with about 100 c.c. of water. Traces of a reddish oil separated and were removed by filtration. After the filtrate had been made slightly alkaline with 10*N*-sodium hydroxide solution, the white flocculent precipitate was filtered off and dried on the water-bath; yield 1.2 g. Recrystallised from aqueous ethanol, this yielded 0.7 g. of long white needles of 2-chloro-*p*-phenanthroline, m. p. 189—190° (Found: C, 66.6; H, 3.7. $C_{12}H_7N_2Cl$ requires C, 67.1; H, 3.3%).

(2) From 1-methyl-*p*-phenanthrol-2-one. A mixture of 1-methyl-*p*-phenanthrol-2-one (8 g.), phosphorus pentachloride (8 g.), and phosphorus oxychloride (48 c.c.) was divided into two parts and heated in two sealed tubes for 5 hours at 150°. After removal of excess of oxychloride by distillation in a vacuum, the reddish product was treated with ice, the solution made alkaline with ammonia, and the precipitate collected, washed with water, and dried on the water-bath, yielding 3.6 g. of a greyish-brown powder, m. p. 188°; recrystallised from ligroin, it formed white needles, m. p. 191° (Found: C, 67.1; H, 3.6%), showing no depression on admixture with a sample prepared as in (1).

p-Phenanthroline *N*-Oxide.—*p*-Phenanthroline (10 g., m. p. 172°), dissolved in dry chloroform (60 c.c.), was mixed with a solution of perbenzoic acid (8 g.) in chloroform (420 c.c.) (prepared as in *Org. Synth.*, Coll. Vol. I, 1st edn., p. 422). The mixture was kept below 0° for 24 hours, the chloroform removed, the

residue extracted four times with 10-c.c. portions of 2*N*-hydrochloric acid, and the extract rendered alkaline and extracted with chloroform (10-c.c. portions). The first six extracts on removal of the chloroform yielded material, m. p. 200—210° (4.5 g.), which after two recrystallisations from ethanol yielded white needles of *p*-phenanthroline *N*-oxide, m. p. 233—234° (3.5 g.) (Found: C, 73.8; H, 4.2. $C_{14}H_{11}N_2O$ requires C, 73.5; H, 4.1%). Further chloroform extracts yielded some impure di-*N*-oxide (2 g.).

p-Phenanthroline Di-*N*-oxide.—*p*-Phenanthroline (10 g., m. p. 172°), dissolved in dry chloroform (60 c.c.), was mixed with a solution of perbenzoic acid (12 g.) in chloroform (1030 c.c.) and kept below 0° for 2 days. Pale yellow needles, which separated, were collected, drained, washed with chloroform, and dried (11 g., m. p. 320—321°). The filtrate was evaporated to dryness, the residue extracted three times with 10-c.c. portions of 2*N*-hydrochloric acid, and the extract made alkaline with 10*N*-sodium hydroxide solution and extracted with chloroform. On removal of the chloroform, 0.2 g. of m. p. 309—310° was obtained. The total crude product was recrystallised from hot water, yielding white needles (8.8 g., m. p. 324—325°) (Found: C, 68.3; H, 4.1; N, 13.7. Calc. for $C_{14}H_{11}O_2N_2$: C, 67.9; H, 3.8; N, 13.2%).

2-Chloro-*p*-phenanthroline from *p*-Phenanthroline *N*-Oxide.—Phosphorus oxychloride (3 c.c.) was added to the dry oxide (1 g., m. p. 232—233°), heat being evolved. The mixture was refluxed for 2 hours at 120—125°, the excess of oxychloride removed in a vacuum, and the greyish syrup treated with cold water (25 c.c.). The solution was rendered alkaline with 10*N*-sodium hydroxide solution, the deposited solid collected after 24 hours, drained, washed with water, dried, and recrystallised from ethanol; yield 0.3 g., m. p. 190—191° undepressed on admixture with a specimen prepared as above.

2-Keto-1-methyl-1:2-dihydro-*p*-phenanthroline Methiodide.—1-Methyl-*p*-phenanthroline-2-one (0.6 g.) was heated under reflux with methyl iodide (4 c.c.) in nitrobenzene (10 c.c.) for 8 hours on a water-bath. The mixture was cooled, and the crystals collected, washed with fresh nitrobenzene, and dried, m. p. 289—290°. Recrystallisation from methanol gave yellow needles of 2-keto-1-methyl-1:2-dihydro-*p*-phenanthroline methiodide, m. p. 290—291° (Found: C, 47.9; H, 3.9. $C_{14}H_{13}N_2I$ requires C, 47.7; H, 3.7%).

2:7-Diketo-1:8-dimethyl-1:2:7:8-tetrahydro-*p*-phenanthroline.—A solution of sodium hydroxide (0.3 g.) in water (7.2 c.c.) and a solution of potassium ferricyanide (1.6 g.) in water (15 c.c.) were added alternately to a solution of 1-methyl-*p*-phenanthroline-2-one methiodide (0.7 g.) in water (36 c.c.), and the solution kept for $\frac{1}{2}$ hour at room temperature. The deposited crystals were collected and 10*N*-sodium hydroxide solution (18 c.c.) was added to the filtrate, whereupon more crystals separated; recrystallisation of the crude material from water gave yellow needles of 2:7-diketo-1:8-dimethyl-1:2:7:8-tetrahydro-*p*-phenanthroline (0.4 g., m. p. 363—364°) (Found: C, 67.0; H, 5.1; N, 11.3. $C_{14}H_{12}O_2N_2 \cdot \frac{1}{2}H_2O$ requires C, 67.5; H, 5.2; N, 11.2%).

2:7-Dichloro-*p*-phenanthroline.—(1) A mixture of the foregoing compound (0.2 g.), phosphorus pentachloride (1 g.), and phosphorus oxychloride (3 c.c.) was heated in a sealed tube for 24 hours at 150°. The excess of oxychloride was decomposed with iced water, and the solution made strongly alkaline with 10*N*-sodium hydroxide solution. The deposited greyish material was collected, washed with water, dried in a vacuum, extracted with hot ethanol, and the concentrated extract allowed to crystallise, yielding white needles, m. p. 310—311°; further crystallisation from ethanol yielded 2:7-dichloro-*p*-phenanthroline, m. p. 315—316° (Found: C, 53.6; H, 2.7; N, 10.1. $C_{12}H_8N_2Cl_2 \cdot H_2O$ requires C, 53.9; H, 3.0; N, 10.5%).

(2) Phosphorus oxychloride (24 c.c.) was added to dry *p*-phenanthroline di-*N*-oxide (2 g.), heat being evolved. The mixture was heated at 125° for 5 hours, the excess of oxychloride removed in a vacuum, and the residue dissolved in 11*N*-hydrochloric acid (40—50 c.c.) to give a muddy brown solution which was rendered alkaline with 10*N*-sodium hydroxide solution to precipitate whitish material which was collected and dried, m. p. 240—250°. Prolonged extraction (1 day) with hot ethanol yielded 1 g. of material, m. p. 300—310°, which on recrystallisation from ethanol yielded 0.2 g. of 2:7-dichloro-*p*-phenanthroline, m. p. 315—316°; mixed m. p. with a sample prepared as above showed no depression.

2-(2-Diethylaminoethylamino)-*p*-phenanthroline.—2-Chloro-*p*-phenanthroline (0.4 g.) was refluxed with 2-diethylaminoethylamine (1 c.c.) at 140° for 3 hours. The excess of the latter was removed in a vacuum on a boiling water-bath to yield a solid yellow residue; this was dissolved in ethanol, and to it were added a few drops of ethanolic hydrobromic acid followed by a few drops of acetone, affording cream platelets of the hydrobromide (0.3 g.), m. p. 284—285° (Found: C, 40.0; H, 5.0. $C_{14}H_{22}N_4 \cdot 3HBr$ requires C, 40.2; H, 4.65%).

2-(3-Diethylaminopropylamino)-*p*-phenanthroline.—2-Chloro-*p*-phenanthroline (0.5 g.) was refluxed with 3-diethylaminopropylamine (1 c.c.) for 2 hours at 160°. When the product was worked up as above, but without addition of acetone, it afforded a hydrobromide which, recrystallised three times from ethanol, yielded pale yellow platelets (0.3 g.), m. p. 268—270° (Found: C, 39.9; H, 4.9; N, 9.8. $C_{14}H_{24}N_4 \cdot 3HBr \cdot H_2O$ requires C, 40.1; H, 5.1; N, 9.8%).

2-(4-Diethylamino-1-methylbutylamino)-*p*-phenanthroline.—2-Chloro-*p*-phenanthroline (0.2 g.) was refluxed with 4-diethylamino-1-methylbutylamine (0.4 c.c.) for 5 hours at 180°. The excess of reagent was removed in a vacuum, the syrupy residue dissolved in ethanol, and a few drops of a saturated ethanolic solution of 3:5-dinitrobenzoic acid added. An oil was deposited which solidified on standing for 2 weeks. The collected *tris*-3:5-dinitrobenzoate, recrystallised five times from ethanol, had m. p. 93—94° (Found: C, 51.8, 52.4; H, 4.8, 4.7; N, 14.1. $C_{21}H_{28}N_4 \cdot 3C_7H_4O_6N_2 \cdot C_2H_5OH$ requires C, 52.0; H, 4.5; N, 13.7%).

We have to acknowledge our indebtedness to Miss A. Weatherhead who first prepared *p*-phenanthroline *N*-oxide, and we thank the Medical Research Council for a grant which defrayed part of the expenses of this work.

332. The Crystal Structure of CsCuCl_3 and the Crystal Chemistry of Complex Halides ABX_3 .

By A. F. WELLS.

The crystal structure of CsCuCl_3 is determined. The crystals are hexagonal, $a = 7.20$, $c = 18.00$ Å.; space-group $C6_2$, with 6 molecules of CsCuCl_3 per cell. There are infinite chain ions of composition $(\text{CuCl}_3)_n^{2-}$ formed by planar CuCl_3 groups joined up by sharing two adjacent chlorine atoms, these ions being in the form of spirals around the six-fold screw axes. They are held together laterally by the caesium ions. The crystal chemistry of complex halides ABX_3 is discussed.

THE structure of the compound CsCuCl_3 is of interest both in connection with the stereochemistry of copper and also because of its close relation to a number of other halides ABX_3 , in which the A and X atoms together are close-packed. Except for the hydrated compounds $\text{CuCl}_3 \cdot 2\text{H}_2\text{O}$ (Harker, *Z. Krist.*, 1936, **93**, 136; MacGillavry and Bijvoet, *ibid.*, 1936, **94**, 231) and $\text{K}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O}$ (Chrobak, *ibid.*, 1934, **88**, 35), little is known of the structures of cupric halides, simple or complex. The crystal structures of the cupric halides themselves are not known, and only the unit-cell dimensions and space-groups of the compounds KCuBr_3 (Silberstein, *Compt. rend.*, 1939, **209**, 540) and Cs_2CuCl_4 (Mellor, *Z. Krist.*, 1939, **101**, 160) have been determined. A note on CsCuCl_3 was published recently (Klug and Sears, *J. Amer. Chem. Soc.*, 1946, **68**, 1133) but the authors were unable to determine its crystal structure.

In the Periodic Table the elements around copper which exhibit bivalency are :

Mn	Fe	Co	Ni	Cu	Zn
			Pd	(Ag)	Cd

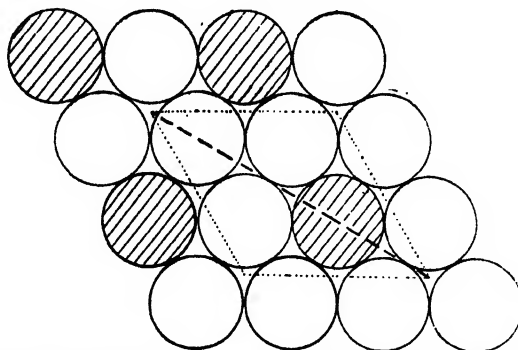

As regards its crystal chemistry Cu^{II} appear to be most closely related to Pd^{II} . For instance, the monoxides MnO , FeO , CoO , NiO , and CdO have the rock-salt structure, ZnO the wurtzite and the zinc-blende structure, but CuO a quite different structure, very similar to that of PdO , in which there is square co-ordination of the metal atoms by oxygen. The difluorides MnF_2 , FeF_2 , CoF_2 , NiF_2 , and ZnF_2 have the rutile structure, and CdF_2 the fluorite structure. CuF_2 apparently has neither of these structures (v. Wartenberg and Laves, *Z. anorg. Chem.*, 1939, **281**, 381); that of PdF_2 is unknown. The dichlorides of Mn, Fe, Co, Ni, Zn, and Cd all crystallise with the cadmium chloride structure, in which a metal atom forms six octahedral bonds, but crystalline PdCl_2 is built up of infinite chains in which each Pd forms four planar bonds. The bonds formed by the former elements in complex halides are discussed later. It will be shown in this paper that in CsCuCl_3 copper forms four planar bonds, again resembling Pd^{II} rather than the other elements mentioned above. The relation of the structure of CsCuCl_3 to that of CsAuCl_3 and other halides ABX_3 will be discussed later.

Determination of the Crystal Structure.—Crystals of CsCuCl_3 are readily grown from an aqueous solution containing caesium chloride and an excess of cupric chloride. The garnet-red crystals are hexagonal prisms $\{10\bar{1}0\}$ terminated by bipyramids, or, if grown slowly, essentially bipyramids $\{10\bar{1}1\}$. They are uniaxial and exhibit dichroism, the colour transmitted being brownish-red for vibrations along c and yellowish for vibrations perpendicular to c . No pyro-electric effect has been detected. The cell dimensions, $a = 7.20$ Å., $c = 18.00$ Å., are in good agreement with the values given by Klug and Sears (*loc. cit.*). The density, 3.65 g./c.c., indicates that the unit cell contains 6 CsCuCl_3 molecules. X-Ray photographs (Cu-K_α radiation) show that the Laue symmetry is $6/mmm$. The only systematic absences observed were in the orders $000l$, which appear only for $l = 6n$, indicating the space-group $C6_2$ (or $C6_2$). The crystal class 62 is consistent with the face development.

The cell dimensions are closely related to those of $\text{Cs}_3\text{Ti}_2\text{Cl}_9$ (Powell and Wells, *J.*, 1935, 1008; Hoard and Goldstein, *J. Chem. Physics*, 1935, **3**, 199), for which $a = 12.82$ ($=\sqrt{3} \times 7.40$), $c = 18.27$ Å., and suggest that the structure of CsCuCl_3 also consists essentially of six close-packed (CsCl_3) layers of the type shown in Fig. 1. In the investigation of $\text{Cs}_3\text{Ti}_2\text{Cl}_9$ it was found that lamellar twinning, leading to a higher apparent symmetry, usually occurred. Crystals of CsCuCl_3 were therefore grown both very rapidly and very slowly, and their X-ray photographs compared. No differences were detected, and it was assumed that twinning of the type encountered in the thallium compound was not occurring in this compound. In $\text{Cs}_3\text{Ti}_2\text{Cl}_9$ the thallium atoms are arranged in pairs of adjacent octahedral holes between the close-packed layers. Since an octahedral environment of 6 Cl (at about 2.5 Å.) would not be unreasonable for copper, it was decided first to try all the possible arrangements of copper atoms in octahedral

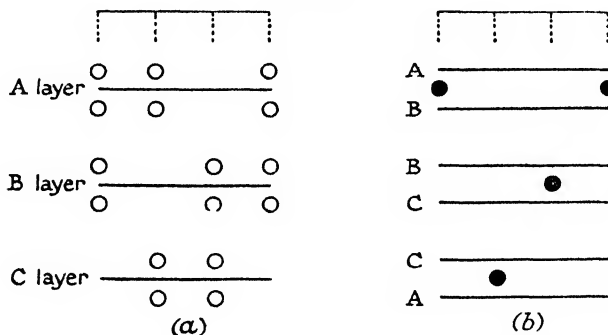

holes. For any structure consisting of six close-packed layers, which contain all the Cs and Cl atoms, the orders of 000 l with $l \neq 6n$ will occur only (1) if the layers are displaced from their ideal heights, $c/6$ apart, or (2) if the Cu atoms are placed in such positions as to contribute to these orders. The survey of possible structures based on octahedrally co-ordinated copper was therefore not restricted to those containing 6_1 (or 6_2) axes, but was carried out in the most exhaustive way in order to eliminate such structures conclusively.

FIG. 1.

Close-packed $CsCl_3$ layer (caesium ions represented by shaded circles).

The problem is to determine the possible structures built of six close-packed layers, each of composition $CsCl_3$, held together by 6 Cu placed in octahedral holes between sets of 3 Cl in adjacent layers. Adopting the conventional nomenclature, each layer may be an A, B, or C layer (*i.e.*, the Cs is at $\frac{1}{3}, \frac{2}{3}$ or 00), with the provisos that similar layers may not be adjacent, and the repeat unit along the c axis must not exceed 6 layers. It is necessary to place one Cu between each pair of layers, for the following reason. The possible positions for Cu atoms lie on the lines 00 z , $\frac{1}{3}z$ or $\frac{2}{3}z$, but on either side of a layer of a given type only two of these positions are possible. Representing the long diagonal of the base of the unit cell (the broken line in Fig. 1) as a horizontal line, we may indicate these possibilities as in Fig. 2*a*, so that between

FIG. 2.

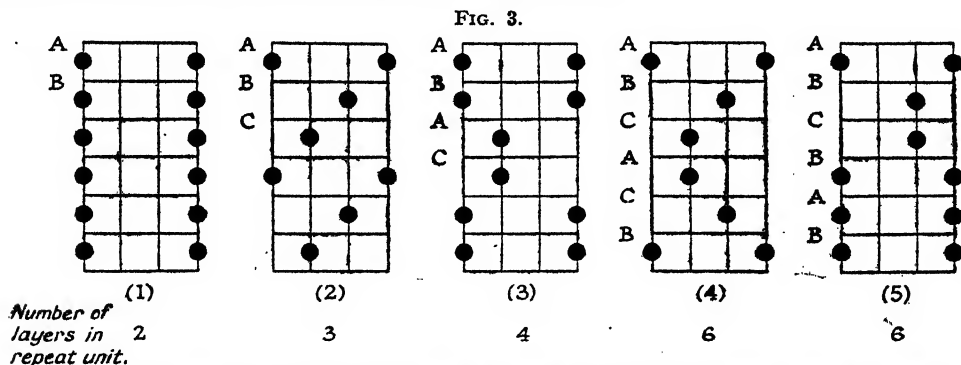

Possible positions of Cu atoms : (a) on either side of an A, B, or C layer ; (b) between AB, BC, or CA layers.

layers AB, BC, CA the only possible positions for Cu are those shown at (b), Fig. 2. The various sequences of layers lead to five possible structures. These are summarised diagrammatically in Fig. 3 as elevations on (11 $\bar{2}$ 0) of one unit cell.

If a layer is represented by h when the two surrounding layers are of the same type, and by c if they are of different types, then the sequences of close-packed layers in these structures are (1) h , (2) c , (3) hc , (4) hcc , (5) $h h h c h c$. Of these the first four are well known as the four simplest types of close-packing. In the first two, hexagonal and cubic close-packing respectively, all the spheres are equivalent; in the second two there are two kinds of non-equivalent spheres. The fifth structure is of a more complex type, and contains four kinds of non-equivalent spheres—

it is interesting as the only one of the six-term set with a repeat unit of only six layers.* In structure (1) there are infinite chains of octahedra formed by sharing opposite faces. Structure (2) is the perovskite structure. The only structures to be tested are (4) and (5), both of which contain infinite 3-dimensional $(\text{MX}_6)_n$ ions formed by MX_6 octahedra sharing all their X atoms with other octahedra. The mode of linking of the octahedra is discussed later. Both these structures can be built up to conform to the space-group $C6m2$, but a comparison of intensities calculated on the basis of either of these structures with those observed for CsCuCl_3 shows that neither is the structure of this compound. In $C6m2$ the only variable x parameters are those of the chlorine atoms, and no small modification of the ideal structures could possibly account for the observed intensities. For example, they both give $F_{600} = F_{006}$ and $F_{601} = 0$, whereas 600 is quite weak and $601 > 600$. It is therefore concluded that CsCuCl_3 does not possess a structure in which Cu is octahedrally co-ordinated by six chlorine atoms.

Possible structures for a complex halide CsMCl_3 , assuming octahedral co-ordination of M atoms (diagrammatic).

To account for the general nature of the $h00$ and $hk0$ intensities it is necessary to shift the close-packed layers relative to one another. Starting with structure (1), with hexagonal close-packing of $(\text{Cs} + 3\text{Cl})$ and Cu atoms with six octahedral neighbours at about 2.5 Å., it is possible by suitable translations of the layers relative to one another to give each Cu four nearest Cl neighbours at about 2.3 Å. and two more distant neighbours. The relation between a pair of adjacent layers is that shown in Fig. 4. In order to fit this new arrangement into the space-group $C6_2$ the three chlorine atoms in any layer are no longer equivalent, and the centre of the (distorted) octahedron of chlorine atoms now lies off the line $00z$. The Cu atoms are therefore arranged around the screw axis in a spiral arrangement. Slight movements from the positions in the ideal close-packed layer of Fig. 1 were necessary to improve the agreement between observed and calculated intensities, and the following parameters were finally chosen as giving the best overall agreement:

Cu: $6(a)$, $x00$, etc., $x = 0.07$

Cs: $6(b)$, $x, 2x, \frac{1}{2}$, etc., $x = 0.345$

Cl_1 : $6(b)$, $x, 2x, \frac{1}{2}$, etc., $x = 0.90$

Cl_2 : $12(c)$, xyz , etc., $x = 0.35, y = 0.22, z = 0.25$

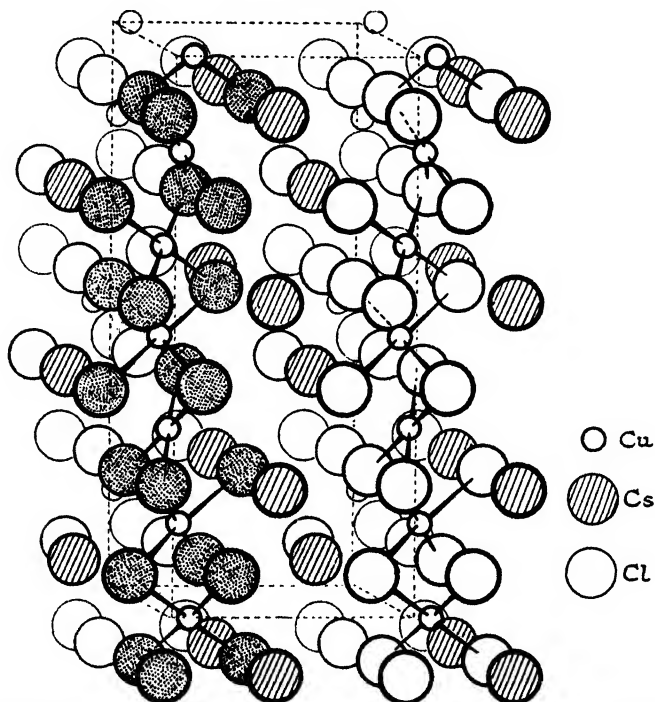

* The simplest close-packed arrangements are tabulated below, together with the numbers of layers in a repeat unit. Certain of these, containing only two types of non-equivalent atom, have recently been discussed by Hägg (*Arkiv Kemi, Min. Geol.*, 1942, **18**, B, No. 3), in connection with the structures of the cadmium halides.

in a structure in which the bonds differ appreciably in amount of ionic character. Absorption of Cu-K_α radiation by this crystal is appreciable, necessitating the use of a very small equidimensional crystal. A temperature factor has not been incorporated into the calculated intensities, nor has allowance been made for absorption, the effect of which may be appreciable for some reflexions.

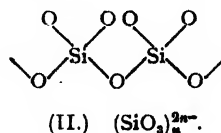

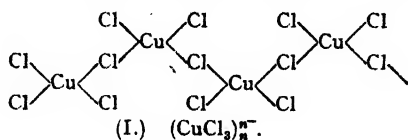

Description of the Structure.—The structure, which is illustrated in Fig. 5, consists essentially of close-packed layers of composition $(\text{CsCl}_3)_n$, arranged approximately in hexagonal close-packing, with the copper atoms between the layers surrounded by four chlorine atoms in a square planar configuration. The next nearest neighbours of a copper atom are two more chlorine atoms,

FIG. 5.

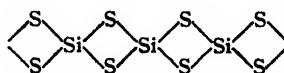

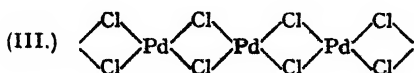

Unit cell of the crystal structure of CsCuCl_3 . The stippled circles represent chlorine atoms forming part of one $(\text{CuCl}_3)_n^{2n-}$ ion.

forming with the other four a somewhat distorted octahedron. The square CuCl_4 groups are arranged in a spiral around six-fold screw axes and are joined up, by sharing two adjacent corners, to form infinite chains of composition $(\text{CuCl}_3)_n^{2n-}$. The structure may therefore be regarded alternatively as consisting of infinite chain ions $(\text{CuCl}_3)_n^{2n-}$ held together laterally by Cs^+ ions. This chain ion (I) is the analogue, for 4-square co-ordination, of the $(\text{SiO}_3)_n^{2n-}$ ion in diopside (II), in which tetrahedral SiO_4 groups are joined up by sharing corners. The infinite

linear molecules in PdCl_2 , formed by planar PdCl_2 groups sharing opposite edges, are related in a similar way to the infinite chain molecules in SiS_2 , which contains tetrahedral SiS_4 units (III).

From the parameters given above the following interatomic distances are calculated :

Cu :	{ 2 Cl at 2.30 Å.	Cs :	6 Cl in same close-packed plane 3.40—3.82 Å.; mean, 3.64 Å.
	2 Cl at 2.27 Å.		4 Cl in adjacent planes, 3.56—3.69 Å.; mean, 3.63 Å.
	2 Cl at 2.65 Å.		2 Cl in adjacent planes, 4.13 Å.

The Cu—Cl bond length is, to within the probable accuracy, the same as that found in $K_2CuCl_4 \cdot 2H_2O$ and $CuCl_2 \cdot 2H_2O$.

Discussion.—The adoption of this structure by $CsCuCl_3$ emphasises the point made in the introduction, that in its crystalline compounds bivalent copper tends to resemble Pd^{II} rather than the elements Co, Ni, or Zn. It has been shown that there are several possible structures for $CsCuCl_3$ containing 6-co-ordinated cupric ions with Cu—Cl about 2.5 Å., with an equally satisfactory packing of Cs^+ and Cl^- ions. In preference to these, however, $CsCuCl_3$ adopts a structure with a distorted Cs—Cl packing in order that the copper atoms shall have only four nearest neighbours arranged at the corners of a square.

It is worth while considering briefly the general nature of the structures shown in Fig. 3, as this is of interest in connexion with the stability of complex halides $CsMCl_3$. In the perovskite structure, ABX_3 , every BX_6 octahedron shares its corners with 6 other such octahedra, while in structure (1), Fig. 3, the octahedra are joined together into chains by sharing opposite faces. This type of complex ion has so far not been found, and may well be unstable owing to the close approach of the two B atoms. The linking of such octahedral co-ordination groups by sharing faces is not known to proceed beyond the formation of the ion $(B_2X_9)^-$, in $Cs_3Ti_2Cl_9$, etc. In such an ion the repulsion of the B atoms does lead to some distortion of the BX_6 octahedra, a type of distortion which is not possible if the linking of octahedra proceeds further. The remaining three structures in Fig. 3, viz., (3), (4), and (5), are, as regards the mode of linking of the BX_6 octahedra, intermediate in nature between structures (1) and (2). In structure (3) all the BX_6 octahedra are equivalent and share three corners with other octahedra and the remaining three (a face) with a fourth octahedron. In structures (4) and (5), however, the BX_6 octahedra are no longer all equivalent. In (4), two-thirds share a face and three corners, one-third six corners, while in (5) two-thirds share a face and three corners and the remainder two faces. It seems probable, therefore, that all the structures (1), (3), (4), and (5) in Fig. 3 would be less stable than (2), the perovskite structure, so that we should expect halides KMF_3 or $CsMCl_3$ containing octahedrally co-ordinated atoms, if they are formed at all, to have that structure. Now, although the simple halides MCl_2 of Fe, Co, Ni, and Zn all crystallise with a structure in which the metal atom is surrounded by six chlorine atom at about 2.5 Å., stable complex halides $CsMCl_3$ are rare. Moreover, in the complex halides they do form they exhibit, in the compounds so far studied, a lower co-ordination number than in the simple halide. (It should be remarked that cadmium behaves differently from the above elements and retains 6-co-ordination in its complex halides, which are therefore different structurally, and also often in formula type, from those of Fe^{II} , Co, Ni, and Zn.)

⁴ Established in $RbCdCl_3$ (MacGillavry, Nijveld, Dierdorp, and Karsten, *Rec. Trav. chim.*, 1939, 58, 193).

Table II gives a general, though rather incomplete, picture of the types of complex chloride formed by these elements which can be isolated from aqueous solution at 25°. Of the elements Fe^{II} , Co, Ni, and Zn, apparently only Ni forms a halide of the type CsMCl_3 (Campbell, *Amer. J. Sci.*, 1894, 48, 418; *Z. anorg. Chem.*, 1895, 8, 126). The salt CsNiCl_3 is obtained by evaporating a concentrated solution containing 12 CsCl : 1 NiCl_2 , and it is immediately decomposed by water. Its structure is not known. In the case of iron and cobalt, the dihydrates are obtained. It would seem that the compounds CsFeCl_3 , etc., are on the borderline as regards stability towards water, and that while CsNiCl_3 can just be prepared from aqueous solution in the presence of a very large excess of CsCl , the others take up $2\text{H}_2\text{O}$, presumably between the chains as in $\text{K}_2\text{SnCl}_4 \cdot \text{H}_2\text{O}$. With the smaller rubidium and potassium ions hydration is more frequent and often occurs also in the salts $\text{M}_2\text{FeCl}_4 \cdot 2\text{H}_2\text{O}$, etc., while sodium salts are in general not obtainable at all. This effect is well illustrated by the complex caesium-cobalt chlorides (see Table II) and by the alkali-copper halides:

Cs.	Rb	K.	Na.	Li.
CsCuCl_3	?	KCuCl_3	—	$\text{LiCuCl}_3 \cdot 2\text{H}_2\text{O}$
Cs_2CuCl_4	—	—	None	—
$(\text{Cs}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O})$	—	$\text{K}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O}$	—	—

Whereas CsCuCl_3 is a stable salt, KCuCl_3 is unstable in moist air, decomposing to a mixture of two hydrated salts ($\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ and $\text{K}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O}$), and KCuBr_2 is very hygroscopic. The appearance of a hydrated lithium salt, in contrast to the non-existence of sodium salts, is presumably due to the fact that an entirely different type of structure becomes possible for the very small, tetrahedrally co-ordinated lithium ion. Similar variations in degree of hydration and stability towards water are found in many other series of complex halides, e.g., the dichloriodides, hexachloroplatinates, etc.

This question, why certain compounds are formed by one element and not by others, is obviously of great interest in chemistry. The direct approach would involve the calculation of the lattice energies of all possible structures for the hypothetical compound, but this exhaustive treatment is not likely to be possible in many cases. In general, it is not possible even to deduce all the reasonable structures for a given compound, so that in the most favourable cases we should only be able to say that one or more specified structures would be unstable, without being sure that there are no other structures the compound could adopt.

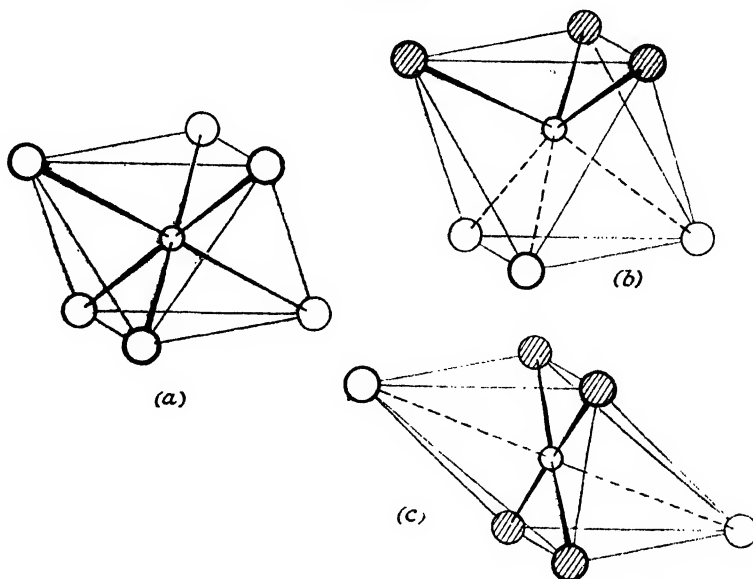

In the case of halides CsMCl_3 (where $\text{M} = \text{Mn, Fe, Co, Ni}$) it would seem that the perovskite structure should be the most stable, it being assumed (1) that the Cs and Cl will be essentially close-packed, and (2) that structures of the type adopted by the larger Cd, containing "band" ions $(\text{CdCl}_3)_n^{2-}$, are not possible for these elements. The instability of these compounds would therefore suggest that the perovskite structure, with linear M-Cl-M bonds, is not stable for chlorides. [It has been stated that CsCdCl_3 (Ferrari and Baroni, *Atti R. Accad. Lincei*, 1927, 6, 418) and CsHgCl_3 (Natta, *ibid.*, 1927, 5, 1003) crystallise with this structure, though the compounds were not studied in any detail. A regular octahedral arrangement of 6 Cl around Hg would be very surprising, but unfortunately the precise location of the relatively light Cl atoms would in any case be very difficult.] The fact that the simple halides MnCl_2 , etc., have the CdCl_2 structure with octahedral co-ordination of the metal atoms shows that it is not the requirement of 6-co-ordination which prevents the complex halides adopting the perovskite structure, but it is significant that in the CdCl_2 structure the chlorine bonds are non-linear. In complex oxides the ideal perovskite structure (with linear -O- bonds) is by no means as common as was once thought (Megaw, *Proc. Physical Soc.*, 1946, 58, 133). We conclude therefore that the instability of these halides CsMCl_3 is due to the fact that the perovskite structure is stable only for the essentially ionic fluorides and oxides of the more electropositive elements. For chlorides it is far less stable than for fluorides, so that instead of CsCoCl_3 we find $\text{CsCoCl}_3 \cdot 2\text{H}_2\text{O}$, with presumably either infinite chain ions $(\text{CoCl}_3)_n^{2-}$, containing tetrahedrally co-ordinated cobalt and H_2O molecules between the chains, or (less probably) infinite aquo-ions or bands as in NH_4CdCl_3 with H_2O between the "band" ions.

The structures of complex halides ABX_3 , in which the ratio of halogen to alkali-metal atoms is 3 : 1 are of special interest because for this ratio the X and A atoms together can form a close-packed array, provided they are of about the same size. The conditions for forming such structures are particularly favourable for K and F and for Cs and Cl, so that in all the following compounds the alkali and halogen atoms are close-packed:

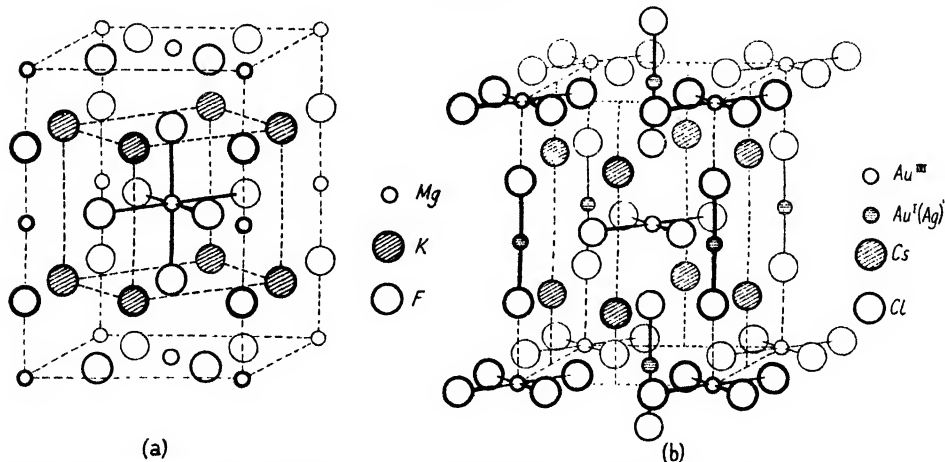

From the geometrical standpoint, the structures of $KMgF_3$, K_2SiF_6 , and $Cs_3Ti_2Cl_9$ differ only in the proportions and arrangement of octahedral holes which are occupied by the more highly charged positive ions, leading in the last two cases to finite $(SiF_6)^{4-}$ and $(Ti_2Cl_9)^{3-}$ ions respectively. In the perovskite structure of $KMgF_3$ no discrete complex ions exist; it is to be regarded as an

FIG. 6.

FIG. 7.

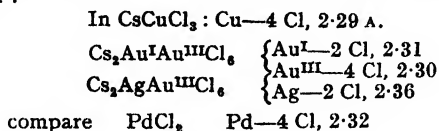

(a) The perovskite structure of $KMgF_3$, with octahedral MgF_6 co-ordination groups; (b) the structure of $Cs_2Au^I Au^{III} Cl_6$ with linear $Au^I Cl_2$ and planar $Au^{III} Cl_4$ groups.

infinite 3-dimensional array of K^+ , Mg^{2+} and F^- ions. For atoms which do not form six octahedral bonds these simple close-packed structures are not possible, and we find interesting variants for $Cs_2As_2Cl_9$ (Hoard and Goldstein, *J. Chem. Physics*, 1935, 3, 117), $CsCuCl_3$, and $CsAuCl_3$. These illustrate three different ways of distorting an octahedral co-ordination group to give less than six nearest neighbours (Figs. 6 and 7), viz., 3 pyramidal (in $Cs_2As_2Cl_9$), 4 planar (in $CsCuCl_3$), and 4-planar or 2 linear neighbours (in $Cs_2Au^I Au^{III} Cl_6$). In $CsCuCl_3$ all the Cu^{II}

1670 Wells: The Crystal Structure of Anhydrous Cupric Chloride

atoms are equivalent and are surrounded by 4 Cl in a plane. The gold compound, although having a similar empirical formula, is of a different kind, containing Au^{I} and Au^{III} atoms in equal numbers. Just as CsCuCl_4 adopts a distorted version of an idealised hexagonal close-packed structure, so the gold compound has a distorted version of the perovskite structure (Elliott and Pauling, *J. Amer. Chem. Soc.*, 1938, 60, 1846). The distortion is of such a nature as to give Au^{I} two nearest neighbours (linear Au^{I} bonds) and Au^{III} four nearest neighbours (4 square Au^{III} bonds), as shown in Fig. 7, (a) and (b). The mixed halide $\text{Cs}_2\text{AgAu}^{\text{III}}\text{Cl}_6$ has the same structure. The bond lengths in the (CuCl_4) , $(\text{Au}^{\text{I}}\text{Cl}_2)$, $(\text{Au}^{\text{III}}\text{Cl}_4)$, and (AgCl_2) groups in these closely related structure are very similar :

We may summarise the crystal chemistry of these complex halides in the scheme below.

333. The Crystal Structure of Anhydrous Cupric Chloride, and the Stereochemistry of the Cupric Atom.

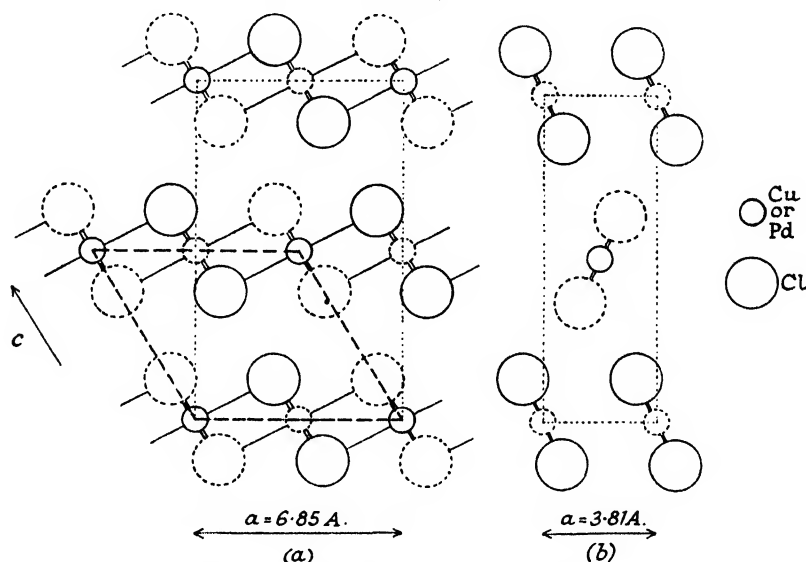

By A. F. WELLS.

Anhydrous cupric chloride is monoclinic: $a = 6.85$, $b = 3.30$, $c = 6.70 \text{ \AA.}$, $\beta = 121^\circ$; space-group C2/m , with Cu at 000, $\frac{1}{2}\frac{1}{2}0$, and 4 Cl at $x0z$, etc., $x \approx \frac{1}{2}$, $z \approx \frac{1}{2}$. The structure contains infinite chain molecules formed by planar CuCl_4 groups sharing opposite edges, as in PdCl_2 . The packing of these chains is different from that found in PdCl_2 , apparently in order to give Cu^{II} two next nearest neighbours at about 3 Å. completing a distorted octahedral co-ordination group. The stereochemistry of the cupric atom is discussed.

CUPRIC chloride is one of the few halides of the commoner elements which has not previously been studied by the methods of X-ray crystallography. Its structure is of interest in view of the planar configuration of four bonds from a cupric atom, already established in a number of crystalline salts and co-ordination compounds. Since the length of a $\text{Cu}^{\text{II}}-\text{Cl}$ bond is the same ($2.30 \pm 0.03 \text{ \AA.}$) as that of $\text{Pd}^{\text{II}}-\text{Cl}$, one might expect cupric chloride to have the same crystal structure as palladous chloride (Wells, *Z. Krist.*, 1938, 100, 189), in which planar PdCl_4 groups are joined up by sharing opposite edges to form infinite chain molecules. In fact, it is found that the structure of CuCl_2 , although closely related to that of PdCl_2 , differs from that structure in a significant way. This point will be discussed later in more detail in a survey of the crystal structures of certain cupric compounds.

Determination of the Crystal Structure of Cupric Chloride.—Cupric chloride is hygroscopic, and is normally obtained from aqueous solution as the dihydrate. The anhydrous salt is readily prepared by heating the dihydrate to a moderate temperature in a stream of hydrogen chloride, being obtained as brown pseudomorphs of the needles of the blue dihydrate. This material is very poorly crystalline, as judged by its powder photograph, and attempts to index the latter unambiguously were not successful. Single crystals of cupric chloride were therefore prepared by melting this material in a hard-glass tube (when some decomposition takes place), allowing it to cool, and breaking up the cooled melt. The crystals are sufficiently stable on a dry day to permit microscopic examination and the selection of suitable crystals which can then be sealed up in short lengths of thin-walled capillary tube. The crystals are thin laths (001) or needles, elongated along the b axis. There is perfect (001) cleavage, and moreover, the slightest pressure on a (001) plate causes it to split along its length (b) into a bundle of fibres, looking much like asbestos. By reflected light the crystals appear brown. They exhibit striking pleochroism, the light transmitted being yellowish-green for vibrations perpendicular to b and reddish-brown

FIG. 1.

Projections of the crystal structures of (a) CuCl_2 and (b) PdCl_2 on (010), showing the differences in packing of the chains. Atoms at $y = 0$ and $y = \frac{1}{2}$ are represented by full and dotted circles respectively. In (a) the broken lines enclose the monoclinic unit cell, and the dotted lines indicate the pseudo-rhombic cell.

for vibrations along b , a colour change quite similar to that of CsCuCl_3 (preceding paper). X-Ray examination (Cu-K_α radiation) shows the crystals to be monoclinic: $a = 6.85$, $b = 3.30$, $c = 6.70$ Å., $\beta = 121^\circ$. Owing to the physical weakness of the crystals, which are easily bent and split, the accuracy of these figures is probably no greater than $\pm 1\%$. The density was not determined, but since by analogy with the structure of PdCl_2 the above cell contains 2 CuCl_2 , the calculated density is 3.44 g./c.c.

The halvings observed are those characteristic of a c face-centred lattice. Since there is no evidence of lower symmetry the space-group is assumed to be $C2/m$. The strong absorption of light vibrating along b and the fact that the length of the b axis is the same as for PdCl_2 suggest a chain structure closely related to that of PdCl_2 . In fact it is found that the photographs about the b axis can be indexed on the basis of a pseudo-rhombic all face-centred cell with dimensions: $a = 6.85$, $b = 3.30$, $c = 11.4$ Å., containing 4 CuCl_2 . The spacings of the $h0l$ planes show also that the projection of the structure on (010) is pseudo-hexagonal. The cell dimensions of PdCl_2 (orthorhombic, space-group $Pnmm$) are: $a = 3.81$, $b = 3.34$, $c = 11.0$ Å., i.e., very similar to those of CuCl_2 except that the a axis is nearly doubled in the case of the latter. This increased a dimension is clearly due to the interposition of a chain related by a translation of $b/2 + a/2$ between alternate chains along the a axis. Since the lattice is known to be c face-centred monoclinic, the only possible way of packing the chains is that shown in Fig. 1(a),

the chain length (b) being normal to the plane of the paper. The corresponding projection of the structure of PdCl_2 is shown in Fig. 1(b). It will be seen that this way of packing the CuCl_2 chains accounts for the pseudo-hexagonal nature of the b axis and for the pseudo-rhombic all face-centred unit cell corresponding to the true orthorhombic cell of the palladium compound.

Considerations of packing show that the planes of the CuCl_2 groups must lie approximately in (100). The structure is then defined as follows, the space-group nomenclature of the International Tables being used:

Cu in 2 (a): 000, $\frac{1}{2}\frac{1}{2}0$

Cl in 4 (i): $x0z$, etc., $x \approx \frac{1}{2}$, $z \approx \frac{1}{2}$

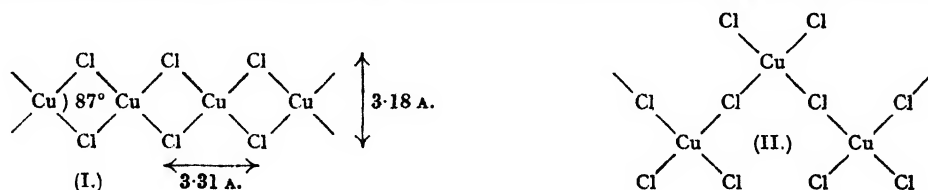

Owing to the fact that the parameters x and z have, at least approximately, the special values $\frac{1}{2}$ and $\frac{1}{2}$ respectively, striking intensity relationships are observed, for all the structure factors have one of the three values, $2f_{\text{Cu}}$, $2f_{\text{Cu}} + 4f_{\text{Cl}}$ or $2f_{\text{Cu}} - 4f_{\text{Cl}}$. Because of the small size of the unit cell, comparatively few reflexions are observed for copper radiation, and the only practicable way of determining the parameters accurately would be to project the structure on (010), using a shorter radiation and, if possible, avoiding the use of a capillary tube. Since it is not likely that better intensity data will be obtainable in the near future, it was considered desirable to publish the present paper as this establishes the structure within close limits and raises an interesting point about the stereochemistry of the cupric atom.

The calculated and observed intensities given in Table I are sufficient to prove the essential correctness of the structure. The intensities are calculated as proportional to $F^2(1 + \cos^2 2\theta/2 \sin 2\theta)$ the f -curves used being those for Cu and Cl atoms given in the International Tables (Vol. II). The planes are arranged in order of increasing $\sin \theta$, and include only those with $h = 0$ or 1.

Description of the Structure.—The structure is illustrated in Fig. 2, which shows three unit cells. The Cu and Cl atoms are joined together to form infinite chains in which each Cu is surrounded by 4 Cl in a plane and each Cl is attached to 2 Cu. From the similarity in the lengths of the b axes in CuCl_2 and PdCl_2 it may be concluded that the structure of a chain is very similar to that in PdCl_2 , viz., (I), though this small distortion of the CuCl_2 groups has not been

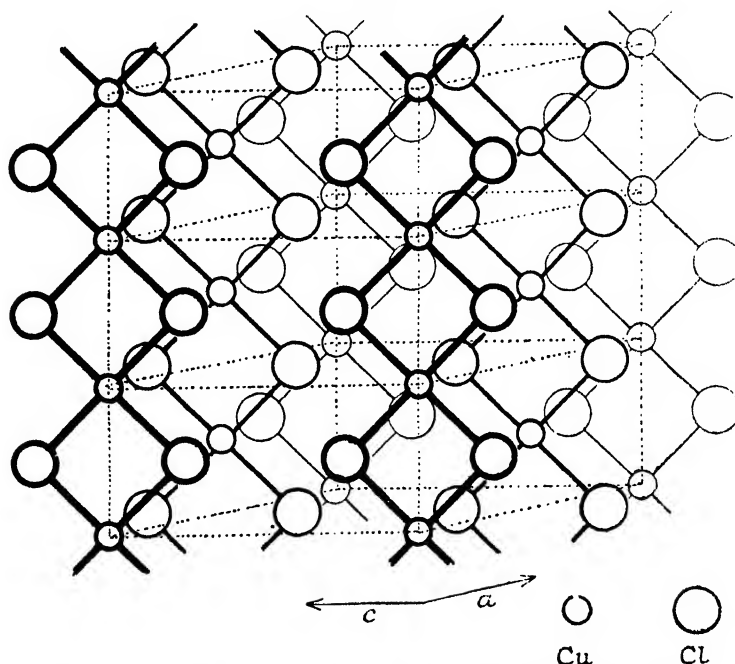

established in the present case. The length of the Cu-Cl bond is the same (2.3 Å.) as that in CsCuCl_2 , $\text{K}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O}$, and $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$. It has been shown (preceding paper) that in CsCuCl_2 exactly similar planar CuCl_2 groups are joined together to form infinite chain ions of the type (II). The configuration of the CuCl_2 chain being assumed to be that shown above, the shortest distance between chlorine atoms of different chains is 3.5 Å. The next nearest neighbours of a copper atom are two more Cl (in adjacent chains related by the c face-centring) at 2.95 ± 0.05 Å. These weak Cu-Cl bonds, discussed below, are shown as light full lines in Fig. 1(a), and they complete the distorted octahedral arrangement of six bonds from each Cu atom. Taking account of this weak additional binding, the chains form sheets parallel to (001), though, of course, by

far the strongest bonds are those within the individual chains, which run parallel to [010]. A somewhat analogous state of affairs is found in the structure of mercuric bromide (Verweel and Bijvoet, *Z. Krist.*, 1931, **77**, 122), in crystals of which each Hg atom has a distorted octahedral environment, with two of the six Br much closer than the other four. Having regard only to the strongest bonds, the structure contains linear molecules HgBr_2 , but taking into account also the weak secondary bonds from a Hg atom to its four next nearest neighbours, the structure is seen to be a layer structure. In PdCl_2 , on the other hand, there is no such suggestion of secondary bonds linking the chains laterally into layers, and the mode of packing of the infinite chains is much more like that of non-polar chain molecules such as long-chain hydrocarbons.

The structure clearly accounts for the strong absorption of light vibrating along the b axis, this being the direction of the infinite chain molecules. The structure also explains the perfect (001) cleavage, and the remarkable tendency to split into fibres is obviously due to the secondary cleavage parallel to (100). The X -ray photographs of some crystals show additional reflexions

FIG. 2.

The crystal structure of anhydrous cupric chloride (three unit cells).

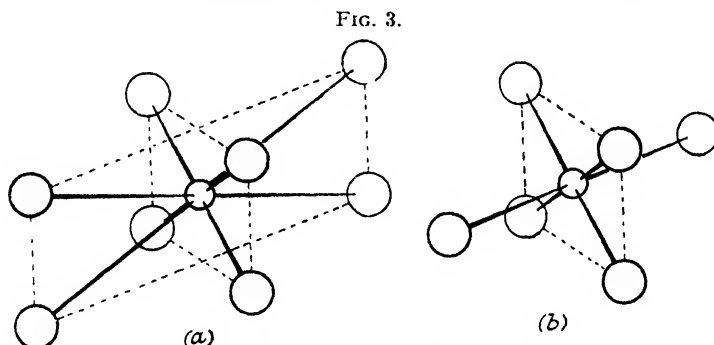

due to twinning, the possibilities of which are considerable. Rotational twinning (about b) is possible because of the pseudo-hexagonal packing of the chains. Also, if the set of chains shown (in projection) in the lower part of Fig. 1(a) is sheared in the direction of the a axis in the plane (001), they can rearrange by sliding over one another to take up the alternative orientation related to the first by reflexion across the plane (201).

The Stereochemistry of the Cupric Atom.—Perhaps the most interesting result of this study is the demonstration that the structure of CuCl_2 is different from that of PdCl_2 . It was known previously that the lengths of the $\text{Cu}^{\text{II}}\text{-Cl}$ and the $\text{Pd}^{\text{II}}\text{-Cl}$ bonds are the same to within the accuracy to which they are known, and the present work confirms this. Both compounds form exactly the same type of infinite chain molecule, yet the chains are packed in different ways in the crystals of CuCl_2 and PdCl_2 . It is worth while enquiring why this should be so. In PdCl_2 , the next nearest chlorine neighbours of a Pd atom (*i.e.*, after the four coplanar neighbours) are four more (at 3.85 Å.) arranged at the corners of a rectangle, the plane of which is perpendicular to that of the PdCl_4 group [see Fig. 3(a)]. In CuCl_2 , on the other hand, neighbouring chains along [100] are displaced relative to one another in such a way that the next nearest neighbours of a Cu atom are two more Cl atoms of neighbouring chains. These complete a distorted octahedron of Cl atoms around the Cu atom [Fig. 3(b)], and they are at a distance of only about

2.95 Å. It might appear fanciful to suppose that the different packing of the chains is adopted in order to give Cu^{II} this distorted octahedral environment, particularly as it is at present difficult to say what type of binding a bond of this length would indicate, were it not for the fact that Cu^{II} has precisely this environment in a number of other crystalline salts. The structures (and stabilities) of certain crystalline cupric salts present a number of striking features to which attention does not appear to have been drawn. The facts are as follows.

(1) *Potassium cupric halides.* The only potassium cupric halide stable in the presence of water at ordinary temperatures is the blue-green hydrated salt $\text{K}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O}$. (The red KCuCl_3 can be prepared from concentrated solution but is rapidly converted by moist air into a mixture of $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ and $\text{K}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O}$.) Palladous chloride on the other hand forms the stable anhydrous K_2PdCl_4 . In crystalline K_2PdCl_4 the PdCl_4^{2-} ions are stacked vertically above one another, so that the next nearest Cl neighbours of a Pd atom (apart from those of other PdCl_4^{2-} ions coplanar with the one under consideration) are 8 Cl at distances of more than 4 Å. In contrast to this, $\text{K}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O}$ does not contain planar CuCl_4^{2-} ions at all, but each Cu has, as nearest neighbours, 2 O (of H_2O) at 1.97 Å., 2 Cl at 2.32 Å., and 2 more Cl at 2.95 Å., the whole set forming a distorted octahedral group around the Cu (Chrobak, *Z. Krist.*, 1934, 88, 35; "Strukturbericht", 1936, 4, 104). In $\text{Pd}(\text{NH}_3)_4\text{Cl}_2 \cdot \text{H}_2\text{O}$ we find Pd with 4 NH_3 as nearest neighbours at 2.02 Å., with 8 Cl as next nearest neighbours, arranged at the corners of a cube, at 4.27 Å. (Dickinson, *Z. Krist.*, 1934, 88, 281).

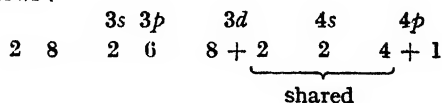

(2) *Cupric chloride dihydrate.* Here again we might have expected to find 4 Cl around Cu at about 2.30 Å. Instead, we find exactly the same arrangement of atoms as in $\text{K}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O}$,

The environment of (a) Pd in PdCl_4 and (b) Cu in CuCl_2 (small circles represent metal atoms).

viz., 2 O at 2.01 Å., 2 Cl at 2.31 Å., and 2 Cl at 2.98 Å. (Harker, *ibid.*, 1936, 93, 136). It may be argued that the displacement of two of the four possible chlorine atoms by 2 H_2O (to give 2 H_2O and 2 Cl as nearest neighbours instead of 4 Cl) is connected with the strong tendency of Cu^{II} to form bonds to oxygen—witness the numerous "basic" salts of copper (actually hydroxy-salts)—but this does not account for the persistent 4 + 2 co-ordination of Cu^{II} which also occurs in anhydrous CuCl_2 and CsCuCl_3 . The comparison of the stereochemistry of Cu^{II} and of Pd^{II} will be more complete when two more structures are known, those of $\text{PdCl}_2 \cdot 2\text{H}_2\text{O}$ and Cs_2CuCl_4 . It will be interesting to know whether the former adopts the same structure as $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ or whether, as seems more likely, Pd will retain 4 Cl as its immediate neighbours. A knowledge of the structure of the latter salt (or some similar compound) is required because the existence of discrete CuCl_4^{2-} ions has not so far been proved in any crystal.

The above considerations suggest that the statement that Cu^{II} forms four coplanar bonds may require modification, in the sense that the analogy with Pd^{II} or Pt^{II} is not so close as that statement would imply: There is, of course, no reason why Cu^{II} should form exactly the same number and arrangement of directed bonds as Ni^{II} , Pd^{II} , or Pt^{II} , and careful comparative studies may indicate more subtle differences between the stereochemical behaviour of atoms which form essentially the same number and arrangement of *strongest* bonds. It is supposed that, when Cu^{II} forms four planar bonds (dsp^2), the 35 valency electrons are distributed among the available orbitals as follows:

the odd electron occupying a $4p$ orbital. In the case of Ni^{III} forming four dsp^3 bonds the electronic arrangement is similar except that there is no odd electron. It seems possible that this electron may have some bonding power and might be responsible for two additional weak bonds perpendicular to the plane of the four strong dsp^3 bonds.

334. Carbohydrate Sulphuric Esters. Part IV. Production of a Derivative of 5:6-Anhydroglucose by the Hydrolysis of a Sulphate.

By R. B. DUFF and E. G. V. PERCIVAL.

By the hydrolysis of barium 3-methyl 1:2-monoacetone glucofuranose 6-sulphate (I), 3-methyl 1:2-monoacetone 5:6-anhydroglucose (II) has been obtained. Unsuccessful attempts to prepare anhydrides from barium 4:6-benzylidene α -methylglucoside sulphate and barium 6-methyl β -methylgalactopyranoside 2-sulphate (VI) are recorded.

IN Part III (J., 1945, 119) it was shown that the hydrolysis with alkali of barium 1:2-monoacetone glucofuranose 6-sulphate yielded 1:2-monoacetone glucofuranose and 1:2-monoacetone 3:6-anhydroglucoside. The failure to identify any *l*-idose derivatives among the products of this hydrolysis was held to prove that no 5:6-anhydride was formed, since Ohle and von Vargha (*Ber.*, 1928, 61, 1203; 1929, 62, 2435) had claimed that, from the corresponding 6-toluene-*p*-sulphonate, 1:2-monoacetone *l*-idofuranose could be obtained *via* the 5:6-anhydride. The basis for this conclusion was destroyed, however, by Seebeck, Meyer, and Reichstein (*Helv. Chim. Acta*, 1944, 27, 1142) who showed that *l*-idose derivatives could not be obtained in this way and that 1:2-monoacetone 5:6-anhydroglucose underwent transformation into the corresponding 3:6-anhydride with great ease. The possibility arose therefore that the 1:2-monoacetone 3:6-anhydroglucose isolated in the experiments from the 6-sulphate (Part III, *loc. cit.*) might have arisen from the 5:6-anhydride as an intermediate.

In order to arrive at an unequivocal decision, a derivative of glucose substituted on C_3 was chosen, to prevent the formation of a 3:6-anhydro-ring. The compound selected, barium 3-methyl 1:2-monoacetone glucofuranose 6-sulphate (I) had the added advantage of solubility in organic solvents which enabled the hydrolysis to be carried out with sodium methoxide instead of aqueous barium hydroxide as in the previous cases (Part III, *loc. cit.*; Part II, J., 1941, 830). Although the method of preparation of (I) does not exclude the possibility that the sulphate group is on C_5 , on general grounds, and by analogy with the reaction with toluene-*p*-sulphonyl chloride (Ohle and von Vargha, *loc. cit.*; Vischer and Reichstein, *Helv. Chim. Acta*, 1944, 27, 1332), this is thought to be highly improbable. Furthermore, it has been shown that by the deacylation of 6-benzoyl 3-benzyl 1:2-monoacetone 5-toluene-*p*-sulphonyl *d*-glucose, 3-benzoyl 1:2-monoacetone 5:6-anhydro-*l*-idose is obtained (Meyer and Reichstein, *Helv. Chim. Acta*, 1946, 29, 152). The possible reaction products in the present case are 3-methyl 1:2-monoacetone glucofuranose by direct hydrolysis and 3-methyl 1:2-monoacetone 5:6-anhydroglucose (II) followed by 3:6-dimethyl 1:2-monoacetone glucofuranose (III) by reaction of (II) with sodium methoxide since the entering methoxyl anion invariably attaches itself to the primary carbon atom (Peat, *Ann. Reports*, 1939, 36, 264).

Experimentally, it was found that although the sulphate group was not removed quite so readily as for the corresponding toluene-*p*-sulphonate, (I) with sodium methoxide (5%) after three hours at 40° gave a transparent barium sulphate gel, and from the reaction mixture 3-methyl 1:2-monoacetone 5:6-anhydroglucose (II, 50%) was obtained, characterised by conversion by sodium methoxide into 3:6-dimethyl 1:2-monoacetone glucofuranose (III)

which on hydrolysis gave crystalline **3** : **6**-dimethyl glucose, identical with an authentic specimen kindly provided by Dr. D. J. Bell, and with specimens prepared by us from **3**-methyl **1** : **2**-monoacetone glucofuranose **6**-toluene-*p*-sulphonate and the corresponding **5** : **6**-ditoluene-*p*-sulphonate.

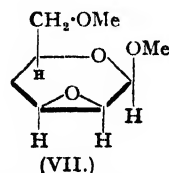

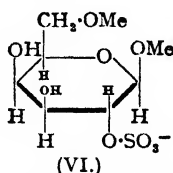

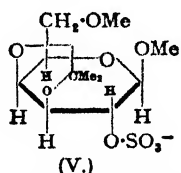

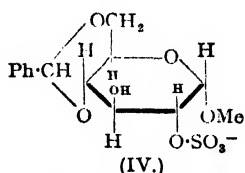

The following table gives the properties of these compounds with the relevant references.

<i>Derivatives prepared from the sulphate (I).</i>	<i>Derivatives prepared from toluene-<i>p</i>-sulphonates.</i>
3 -Methyl monoacetone anhydrohexoside; $n_D^{18} 1.4610$; $[\alpha]_D^{12} -67^\circ$ (<i>c</i> , 4.0 in chloroform)	3 -Methyl 1 : 2 -monoacetone 5 : 6 -anhydroglucose; $n_D^{18} 1.4610$; $[\alpha]_D^{18} -65^\circ \pm 2$ (<i>c</i> , 2.0, in acetone) (Vischer and Reichstein, <i>loc. cit.</i>).
Dimethyl monoacetone hexose; $[\alpha]_D^{18} -46.5^\circ$ (<i>c</i> , 4.5 in chloroform)	3 : 6 -Dimethyl 1 : 2 -monoacetone glucofuranose; $[\alpha]_D^{20} -45.8^\circ$ (<i>c</i> , 4.0 in chloroform) (Bell, <i>J.</i> , 1936, 1553)
Dimethyl hexose; m. p. 115—116°; $[\alpha]_D^{18} +61^\circ$ (<i>c</i> , 0.8 in water at equilibrium)	3 : 6 -Dimethyl glucose; m. p. 114—115°; $[\alpha]_D^{20} +61.6^\circ$ (in water at equilibrium) (Bell, <i>loc. cit.</i>)

There is thus no doubt that ethylene oxide derivatives can be produced from carbohydrate sulphates, and by analogy with the toluene-*p*-sulphonates and methanesulphonates it would be expected that, when the sulphate group is removed from an asymmetric carbon atom with an adjacent *trans*-hydroxyl group, an ethylene oxide ring would be produced with Walden inversion. It is true that the opposite conclusion was reached by one of us (Part III, *loc. cit.*) since the alkaline hydrolysis of barium methylglucoside **3**-sulphate gave only glucose and **3** : **6**-anhydroglucose derivatives, but this could be attributed to the preferential formation of the pentaphan ring.

To test the hypothesis, **4** : **6**-benzylidene α -methylglucoside was treated with chlorosulphonic acid in pyridine to give a barium **4** : **6**-benzylidene α -methylglucoside sulphate. When this was treated in methanol with sodium methoxide, **4** : **6**-benzylidene α -methylglucoside (85%) was recovered and the methoxyl content (10%) of the partly crystalline residue showed that no methoxyl groups had entered the molecule, so that it must be presumed that no ethylene oxide rings had been formed. Whether the product used was a 2-sulphate (IV) or a 3-sulphate, if either had given **2** : **3**-anhydrides, these would certainly have been decomposed by the excess of sodium methoxide with the entry of an additional methoxyl group.

As a further test, **6**-methyl **3** : **4**-monoacetone β -methylgalactoside was synthesised and its structure confirmed by conversion into the known **2** : **6**-dimethyl **3** : **4**-monoacetone β -methylgalactoside (Bell, *J.*, 1945, 692). Barium **6**-methyl **3** : **4**-monoacetone β -methylgalactoside 2-sulphate (V) was then prepared and removal of the isopropylidene residue gave barium **6**-methyl β -methylgalactoside 2-sulphate (VI). When this substance, in methanolic solution, was treated with sodium methoxide, however, no reaction was observed until 90° was reached, whereupon, instead of the production of **6**-methyl **2** : **3**-anhydro- β -methylgalactoside (VII) followed by **2** : **6**-dimethyl β -methylgalactoside or **2** : **6**-dimethyl β -methylidide, or both, rapid darkening of the solution took place with extensive decomposition and the formation of reducing products; no increase in methoxyl content could be detected.

So far, therefore, there is no direct support for the suggestion (*Nature*, 1946, **158**, 29) that sugars may undergo interconversion in *Nature* by way of sulphuric esters and their hydrolysis, even though ethylene oxide formation does occur when the sulphate group on a primary carbon atom is removed. Further work is necessary, however, before this possibility can be abandoned since the behaviour of sulphate residues on C_2 might be anomalous. In connexion with the hydrolysis of (VI) it may be recalled that Helferich and Schnorr (*Annalen*, 1941, **547**, 201) recorded the hydrolysis of a 2-hydroxyethanesulphonic acid glycoside with alkali, and Isbell (*Ann. Rev. Biochem.*, 1943, **12**, 205) has suggested an explanation of this effect in terms of electron displacement initiated by the electronegative sulphonyl group. Until more evidence is available it would be premature to attempt an explanation of the present result, but it is clear that the adjacent sulphate group renders the glycosidic methoxyl labile to alkali. In (VI) it will be noted

that these two groupings are *trans*- to one another which recalls the fact that the alkali fission of the phenylglycosides proceeds most readily when the phenoxy-group is in the *trans*-position with respect to the hydroxyl residue on C₂, as in β -phenylglucoside (Montgomery, Richtmyer, and Hudson, *J. Amer. Chem. Soc.*, 1943, **65**, 1848; *J. Org. Chem.*, 1945, **10**, 194; McCloskey and Coleman, *ibid.*, p. 184). If, as is quite likely, the barium 4 : 6-benzylidene α -methylglucoside sulphate is the 2-sulphate (IV), the sulphate and methoxyl groups are in the *cis*-positions, and this might explain why fission of the glycosidic methoxyl was not observed; it is hoped that further work will illuminate these points.

EXPERIMENTAL.

Barium 3-Methyl 1 : 2-Monoacetone Glucofuranose 6-Sulphate.—3-Methyl 1 : 2-monoacetone glucofuranose was prepared as a colourless syrup by the methods of Freudenberg *et al.* (*Ber.*, 1923, **56**, 1225; 1926, **59**, 104). The product had n_D^{20} 1.4740, $[\alpha]_D^{25}$ -54° (c, 3.1, in chloroform) [Found : OMe, 12.8; (CH₃)₂CO, 23.3. Calc. for C₁₀H₁₄O₆ : OMe, 13.2; (CH₃)₂CO, 24.8%].

Sulphation with chlorosulphonic acid (approx. 1 mol.) in pyridine was carried out as described in Part III (*loc. cit.*). In a typical experiment the above syrup (10.1 g.) in dry pyridine (80 c.c.) was vigorously stirred and treated with chlorosulphonic acid (3.65 c.c.) in chloroform (40 c.c.) at -15° . The mixture was neutralised with barium hydroxide solution, the excess being removed with carbon dioxide; it was found necessary to add alcohol to obtain a homogeneous solution, owing to the solubility of the free 1 : 2-monoacetone 3-methyl glucofuranose sulphate in chloroform with the resulting danger of incomplete neutralisation; in some experiments chloroform was removed under reduced pressure at 15° . The crude barium salt (15 g.) was isolated in the usual way and purified by dissolving in twice the minimum volume of acetone followed by partial precipitation (8.1 g.) with light petroleum (b. p. 60–80°); $[\alpha]_D^{25}$ -19° (c, 1.0, in water) [Found : Ba, 18.5; OMe, 8.7; SO₄, 23.2; (CH₃)₂CO, 15.0. (C₁₀H₁₇OS)₂Ba requires Ba, 18.0; OMe, 8.1; SO₄, 25.2; (CH₃)₂CO, 15.2%].

3-Methyl 1 : 2-Monoacetone 5 : 6-Anhydroglucose.—The above barium salt (3.53 g.) was dissolved in warm anhydrous methanol (10 c.c.) and cooled to room temperature. A solution (6.5 c.c.) of sodium (5%) in methanol was added with stirring and the mixture heated at 40° for 3 hours, whereby the mobile liquid was completely converted into a stiff transparent gel owing to separation of colloidal barium sulphate. The gel was treated with excess of a mixture of chloroform and methanol (1 : 1), and carbon dioxide bubbled through until wet phenolphthalein paper was no longer affected. Water (300 c.c.) was then added followed by repeated extraction with chloroform. The combined extracts were dried (Na₂SO₄) and evaporated at 40°/15 mm.; the residual syrup was distilled at 120–130°/0.02 mm. in the presence of barium carbonate (0.2 g.), to give a colourless mobile oil (1.0 g.), $[\alpha]_D^{25}$ -63° (c, 4.5, in chloroform) (Found : OMe, 16.5. Calc. for C₁₀H₁₄O₅ : OMe, 14.4%). Since it was suspected that this product was contaminated with 3 : 6-dimethyl 1 : 2-monoacetone glucose, the crude oil in chloroform (20 c.c.) was adsorbed on a column of aluminium oxide (30 cm. \times 1 cm.). The column was eluted with 5 portions (20 c.c.) of chloroform, and the syrup (0.4 g.) obtained after removing chloroform from the second fraction gave at 120°/0.01 mm. an oil (0.3 g.) which had the properties required for 3-methyl 1 : 2-monoacetone 5 : 6-anhydroglucose; namely n_D^{20} 1.4610, $[\alpha]_D^{25}$ -67° (c, 4.0 in chloroform) (Found : OMe, 14.3. Calc. for C₁₀H₁₄O₅ : OMe, 14.4%).

3 : 6-Dimethyl 1 : 2-Monoacetone Glucofuranose and 3 : 6-Dimethyl Glucose.—3-Methyl 1 : 2-monoacetone 5 : 6-anhydroglucose (0.5 g.) obtained as described above was heated at 90° with a solution of sodium (0.5 g.) in anhydrous methanol (10 c.c.) for 18 hours. Neutralisation by carbon dioxide, dilution with water, and extraction with chloroform was followed by distillation at 110–120°/0.01 mm. to give an oil (0.3 g.), n_D^{20} 1.4622, $[\alpha]_D^{25}$ -46.5° (c, 4.5 in chloroform) (Found : OMe, 21.5. Calc. for C₁₁H₂₀O₅ : OMe, 25.0%).

The above product (0.2 g.) was left at 37° for 48 hours with sulphuric acid (200 c.c.; 0.2N). Neutralisation with barium carbonate followed by filtration and evaporation at 40°/15 mm. gave a sugar which was twice recrystallised from hot ethyl acetate to give crystals (0.1 g.), $[\alpha]_D^{25}$ $+61^\circ$ (c, 0.8 in water; equilibrium value) (Found : C, 46.0; H, 7.5; OMe, 29.8. Calc. for C₈H₁₆O₆ : C, 46.1; H, 7.7; OMe, 30.0%), m. p. 115–116°, unchanged on admixture with an authentic specimen of 3 : 6-dimethyl glucose provided by Dr. D. J. Bell, and with specimens prepared by the action of sodium methoxide on 3-methyl 1 : 2-monoacetone glucofuranose 6-toluene-*p*-sulphonate (Found : OMe, 7.4. Calc. for C₁₇H₂₄O₈S : OMe, 8.0%), and from 3-methyl 1 : 2-monoacetone glucose 5 : 6-ditoluene-*p*-sulphonate (Found : OMe, 5.5. Calc. for C₂₄H₃₀O₁₀S₂ : OMe, 5.7%).

In another experiment the sulphate (2.0 g.) was heated at 90° for 24 hours with sodium in methanol (25 c.c.; 5%). Neutralisation and isolation as previously described gave an oil (0.5 g.), n_D^{20} 1.4637 (Found : OMe, 22.8%) which was treated with sulphuric acid (0.2N) as before, and the sugar purified by filtration through a column of aluminium oxide to give crystals of 3 : 6-dimethyl glucose, m. p. 114°, not depressed on admixture with an authentic specimen.

Barium 4 : 6-Benzylidene α -Methylglucoside Sulphate.—4 : 6-Benzylidene α -methylglucopyranoside, m. p. 163° (10.5 g.), was sulphated as previously described to yield a product (9.5 g.) having $[\alpha]_D^{25}$ $+39.5^\circ$ (c, 1.2 in water) [Found : Ba, 17.6; SO₄, 23.0; OMe, 8.4. (C₁₄H₁₇O₆S)₂Ba requires Ba, 15.9; SO₄, 22.4; OMe, 7.2%]. This was hydrolysed as previously described with excess of a solution of sodium (5%) in methanol at 15° and at 90°. Four such experiments were conducted and in none was any material other than 4 : 6-benzylidene α -methylglucoside obtained from the hydrolysate. In one experiment barium 4 : 6-benzylidene α -methylglucoside sulphate (8.8 g.) was hydrolysed for 18 hours at 90° with sodium methoxide in methanol. The product was dissolved in ethyl acetate and three crops (5.0 g.) of 4 : 6-benzylidene α -methylglucoside were isolated. The residues gave a partly crystalline substance (0.9 g.) which was chiefly 4 : 6-benzylidene α -methylglucoside (Found : OMe, 10.1%).

6-Methyl 3 : 4-Monoacetone β -Methylgalactoside.—6-Methyl β -methylgalactoside (11.0 g.) was

converted into the monoacetone derivative by the method of Ohle and Thiel (*Ber.*, 1933, **66**, 525) as modified by McPhillamy and Elderfield (*J. Org. Chem.*, 1939, **4**, 150). Distillation at 120°/0.01 mm. gave an oil which crystallised at 0°; recrystallisation from ethyl acetate–light petroleum (b. p. 60–80°) gave a product, m. p. 72–74°, $[\alpha]_D^{18} + 11^\circ$ (c, 1.4 in chloroform) [Found: C, 52.8; H, 8.1; OMe, 23.1; $(CH_3)_2CO$, 25.9. $C_{11}H_{18}O_8$ requires C, 53.2; H, 8.1; OMe, 25.0; $(CH_3)_2CO$, 23.4%].

Two methylations (0.4 g.) with Purdie's reagents followed by distillation at 120°/0.01 mm. gave 2:6-dimethyl 3:4-monoacetone β -methylgalactoside (0.35 g.), $[\alpha]_D^{18} + 2^\circ$ (c, 1.0 in chloroform), m. p. 55–56°, unchanged on mixing with an authentic specimen prepared by Dr. D. J. Bell.

Barium 6-Methyl 3:4-Monoacetone β -Methylgalactoside 2-Sulphate.—6-Methyl 3:4-monoacetone β -methylgalactoside (1.7 g.) was sulphated as previously described to yield a barium salt (3.1 g.), $[\alpha]_D^{18} + 10^\circ$ (c, 1.0 in water) [Found: Ba, 18.0; SO_4 , 24.8; $(CH_3)_2CO$, 13.2. $(C_{11}H_{18}O_8)_2Ba$ requires Ba, 17.4; SO_4 , 24.3; $(CH_3)_2CO$, 14.6%].

Barium 6-Methyl β -Methylgalactoside 2-Sulphate.—The above product (2.7 g.) was treated with sulphuric acid (0.2N) at 37° as previously described to yield a non-reducing barium salt (2.3 g.), $[\alpha]_D^{18} \pm 0^\circ$ (c, 1.0 in water) [Found: Ba, 17.5; SO_4 , 25.6; OMe, 15.4. $(C_8H_{15}O_6)_2Ba \cdot 4H_2O$ requires Ba, 17.5; SO_4 , 24.5; OMe, 15.8%]. To this substance (2.0 g.) in methanol (25 c.c.), a solution of sodium in methanol (50 c.c.; 5%) was added. No reaction took place during 24 hours at 15°, 24 hours at 40°, or 6 hours at 60°. When the temperature was raised to 90°, however, the solution rapidly darkened. After 18 hours at 100° the product was worked up in the usual way to give a dark reducing syrup (0.5 g.; OMe, 25.3%). The syrup obtained from a second experiment had OMe, 21.8%. It is thought probable therefore that the syrups obtained were specimens of 6-methyl β -methylgalactoside (OMe, 29.9%) contaminated with reducing material formed by the fission of the glycosidic methoxyl group.

Thanks are expressed to the Carnegie Trust for the Universities of Scotland for a Scholarship (R. B. D.), to Dr. D. J. Bell for the gift of specimens, and to Imperial Chemical Industries Ltd. and the Earl of Moray Endowment for grants.

335. The Solubility at High Temperatures of Pure Sucrose in Water.

By MILLICENT TAYLOR.

A method of determining the solubility of sucrose at high temperatures has been devised which avoids the necessity of analysis of the solution. In its present form it has been found applicable only to temperatures between 64° and 82°. The relationship between saturation concentration and temperature is expressed by an equation which enables the results to be used in the determination of other thermodynamic properties of sucrose solutions.

THE method to be described was devised with the object of avoiding the filtration at high temperatures and the handling for analytical purposes of highly concentrated, viscous sucrose solutions. The behaviour of a crystal of sucrose in approximately saturated solution of accurately known concentration is observed microscopically during both falling and rising temperature, and the temperatures of incipient healing and erosion are noted. The mean of these two temperatures is taken as the saturation temperature of the solution. The first experiments on these lines were carried out by Dr. A. Wischin, but as she was unable to continue the work, the author undertook preliminary experiments which showed considerable deviation from the results of previous investigators (Herzfeld, *Z. ver. Rübenz.-Ind.*, 1892, 181, 232; Nuszbaum and Grube, *Z. Elektrochem.*, 1928, **34**, 91; Grut, *Z. Zuckerind. Czechoslovak*, 1937, **61**, 356). After some modification of the original apparatus and calibration of all precision instruments, the experiments described below were carried out.

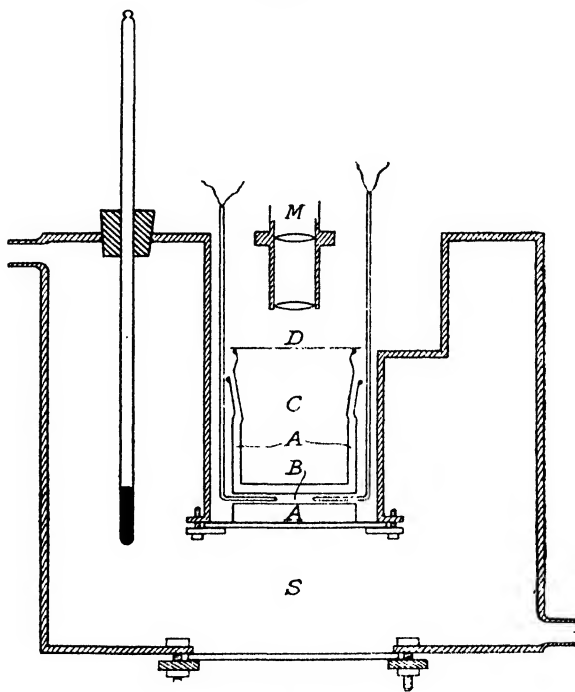

EXPERIMENTAL.

Apparatus.—A glass cell, *A* (Figs. 1 and 2), provided with a horizontal tubular observation shelf, *B*, is closed by a hollow stopper, *C*, the bottom of which is of plane optical glass. The cell slides into a cylindrical water-tight well in the cover of a small lagged thermostat, *S*, the temperature of which is controlled by water pumped from a large thermostat. The lower opening of the well and a corresponding circular opening in the bottom of the thermostat are closed by adaptable plane-glass plates, each held in position by a brass ring and rubber washer. The cell is illuminated through the glass plates by a reflected beam from a 100-watt lamp. A copper–constantan thermocouple consisting of two junctions in series passes into the tubular space under the shelf. The junctions and leads are enclosed for a length of about 8 cm. in very thin drawn-out glass tubing, which is bent at right angles to fit snugly against the side of the cell. A space is left between the junctions to allow of unobstructed microscopic observation of a crystal placed on the shelf between the two junctions. The plate *D*, also of plane optical glass, covering the hollow stopper, is required to prevent irregularities of temperature due to convection currents. Strips of tin foil, in all some 7 or 8 yards in length, are smoothly packed outside the cell and leads, and serve to prevent convection currents in, and to aid conduction of heat across, the annular space surrounding the cell. The latter is also provided with a copper collar carrying a rubber flange which

assists in closing any remaining air space. A mark inside the cell indicates the level at which the solution should stand before insertion of the stopper, which dips considerably under the surface of the solution. A Winkel-Zeiss camera microscope, *M*, which has a visual magnification of about 40 diameters, is used for observation of the crystal.

Calibration.—The thermocouple is calibrated up to 86° on a millivoltmeter reading up to 7 mv., against a standard thermometer (N.P.L.) graduated in 0.1° and correct to 0.02° . For calibration, the thermometer and the thermocouple are immersed to a depth of about 7 cm. in a narrow tube of mercury suspended in a thermostat. The temperature is regulated and read by means of a levelled telescope to about 0.02° . The millivoltmeter is graduated to 0.05 mv. and the reading can be estimated to about 0.005 mv., which corresponds on this instrument, using the two junctions, to approximately 0.05° . The accurate measurement of any temperature difference between the thermocouple under the shelf and the solution on the surface of the latter was initially found to be a matter of some difficulty. The problem was ultimately solved by calibrating the thermocouple *in situ* against the setting or melting points of highly purified samples of palmitic, stearic, and behenic acids, of which the respective setting points are 62.66° , 69.60° , and 80.02° (Professor F. E. Francis, unpublished work). *p*-Chloronitrobenzene, s. p. 83.04° , proves satisfactory at the somewhat higher temperature. The m. p.s were redetermined against

FIG. 1.

Solubility cell in thermostat.

the N.P.L. standard, which was used to calibrate the thermocouple. A sharp m. p. giving reliable results in the second decimal place could not, at first, be obtained. For example, in the case of stearic acid, which gave the least satisfactory value, the recorded m. p. lay between 69.48° and 69.60° . With palmitic acid and behenic acid, the corresponding range was almost negligible. The m. p.s so determined are 62.56° , 69.54° (mean), and 80.00° , respectively.

Two thermocouples, *X* and *Y*, have been used during these experiments. The former was in use during the period when it was impossible to obtain insulating sleeving, and short lengths of drawn-out glass tubing were slid over the leads as a somewhat inconvenient substitute. For the purpose of calibration a small quantity of the ground, purified compound was sealed into a very thin flattened glass tube, which replaced the sucrose crystal on the observation shelf. The cell was then filled up to the mark, in one case with sucrose solution of one of the experimental concentrations, and in another case with water. The change from water to sucrose solution did not affect the readings.

An example of the results obtained by the control calibration of thermocouple *X* is given in Table I.

The use of this mean takes into account the uncertainty in the m. p. of stearic acid and the fact that its m. p. lies between those of the other two acids. Subsequent checking of this calibration showed no significant change in the correction.

When thermocouple *Y* was prepared, insulating sleeving was available and a smoother and more compact tinfoil jacket was applied to the cell. Also, it was found possible to get a sharper comparison of the thermocouple and the standard thermometer by taking as identical in the melting point tube and in the solubility cell the temperature at which crystals shoot out from a partly molten mass, causing the smooth liquid meniscus to become irregular (setting point) or melting back to allow the smooth meniscus

TABLE I.

M. p.s of standards used for calibration of thermocouple X.

Acid.	In m. p. tube.	In solubility cell, read on millivoltmeter.	Correction on thermocouple.
Palmitic	62.56°	62.40°	+0.16°
Stearic	69.54 (mean)	69.45	+0.09
Behenic	80.00	79.84	+0.16
		Mean	+0.16

to re-form (melting point). The difference between the setting and melting points determined in this way lay within the accuracy of calibration of the standard thermometer.

For these reasons, the calibration of thermocouple Y is probably of higher accuracy than that of thermocouple X. The results of the calibration of thermocouple Y are given in Table II.

TABLE II.

M. p.s of standard substances.

Date.	Substance.	In m. p. tube.	In solubility cell, read on millivoltmeter.	Correction on thermocouple.
June, 1945	Palmitic acid	62.62°	62.57°	+0.05°
	Stearic acid	69.54	69.51	+0.03
	<i>p</i> -Chloronitrobenzene	83.04	83.00	+0.04
			Mean	+0.04
Repeated after removal of tinfoil and repacking.				
Sept., 1945	Palmitic acid	62.56	62.57	-0.01
	Stearic acid	69.54	69.55	-0.01
	Behenic acid	79.91	79.94	-0.03
			Mean	-0.02

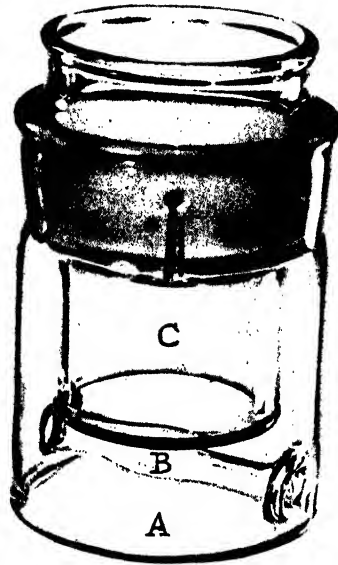

These corrections are within the limits of the error on the thermocouple readings, but they indicate that care must be taken in packing the cell and that frequent recalibration is advisable.

Procedure.—Tate and Lyle's purest sucrose containing on a dry basis 99.99% of sucrose and 0.001—0.003% of invert sugar is very finely ground and dried to constant weight in a vacuum oven under standard conditions (see International Commission for Uniform Methods of Sugar Analysis, London, 1936), *i.e.*, at a temperature not exceeding 60°, in a stream of dried air, the pressure not being allowed to exceed 5 cm. Hg. The air-drying agent used is an activated alumina, having a drying efficiency more than a 1000-fold that of calcium chloride. After being dried, the sucrose is transferred by means of a long, wide thistle funnel to a long-necked, weighed bulb of about 60 c.c. capacity. The lower part of the neck of the bulb has an internal diameter of at least $\frac{1}{8}$ " to allow of unhindered outflow of the viscous solution. The calculated weight of conductivity water for any required concentration is added from a weight burette, provided with a long delivery tube. After thorough mixing at room temperature, the contents of the flask are rapidly frozen in solid carbon dioxide-methylated spirit and after constriction of the neck of the flask the latter is exhausted, the contents are allowed to warm up without admission of air, and the freezing and exhaustion are repeated. The flask is then sealed, subjected to violent automatic shaking for at least an hour at a temperature several degrees higher than the saturation point, and after rapid cooling in ice-water the solution is allowed to reach room temperature for a control weighing.

The seeding crystals, at least two in number and as small as can conveniently be handled, of linear dimensions 0.5—0.25 mm. or less, are placed in position on the shelf of the cell which, with its thermocouple in position, is now connected with the millivoltmeter and is ready to be put into the thermostat. All necessary regulation of the thermostats must be made before the bulb is opened. The cell must, of course, be cold, but the stopper should be slightly warm and greased with a mixture of apiezon grease plus 25% of aluminium stearate. The neck of the bulb, which is clean and dry inside, is then cut across the wide part, and a weighed rubber bung is inserted. After a final control weighing, the result of which has in no case differed by as much as 0.01% from the initial weight of the solution, the latter is cooled to the dew point as determined by a Casella whirling hygrometer, and is quickly poured into the cell. After being closed and before being transferred to the thermostat, the latter is put into a closely fitting, dry beaker and rapidly heated in an electrically controlled water-bath until the temperature indicated by the thermocouple approaches the saturation temperature. The object of this is to check the growth of the seeding crystals and of any centres of crystallisation which are liable to form as the cold solution is poured into the cell. The initial formation of a few such chance crystals may be advantageous as they are very small relatively to the original seeding crystals, are perfectly shaped, and while the smallest disappear rapidly when the saturation temperature is overstepped, a larger one can frequently be retained as a very sensitive temperature indicator. In solutions of higher concentration, 80% and upwards, the deposition of crystals becomes unmanageable, putting an upper limit to the range of concentrations to which this method has been found applicable.

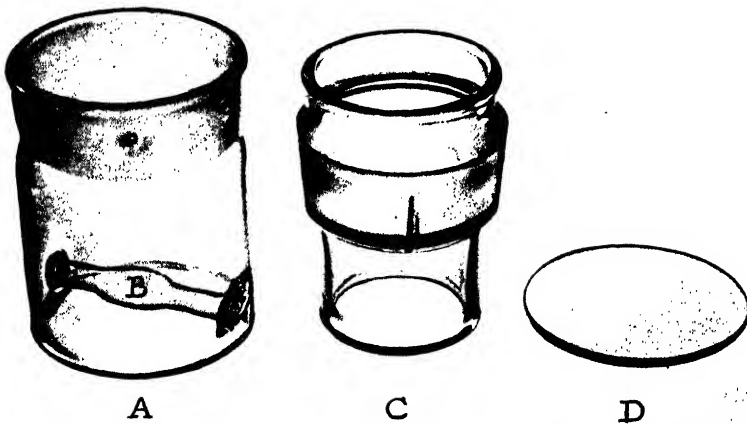

In the thermostat there is considerable time lag in the response of the cell temperature to the thermostat regulation. The lag is probably due to the residual air space in the well of the thermostat and is liable to lead to overstepping of the crucial temperature in either direction. This disadvantage has to some extent been overcome by changing the temperature very slowly. A rate of change of 0.02° per minute has been aimed at, and in most cases it has not been exceeded. A slow rate of change has disadvantages,

FIG. 2a.

Solubility cell. (Actual size.)

FIG. 2b.

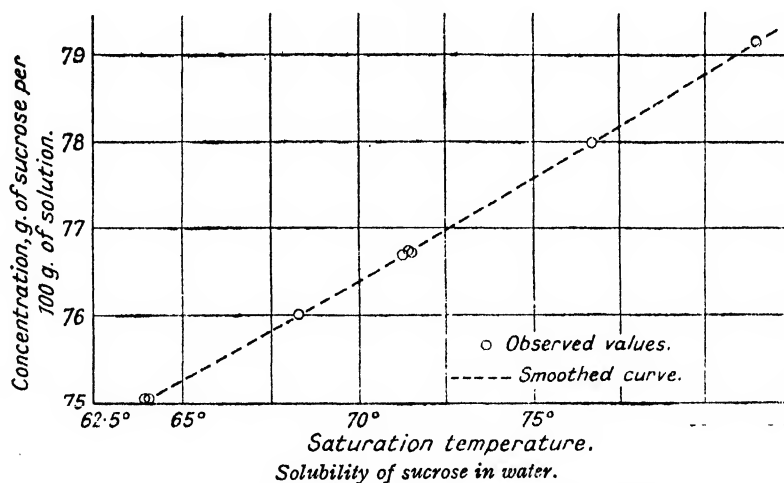

Solubility cell. ($\frac{1}{2}$ Actual size.)

for example, the considerable inversion which is liable to take place, and the possibility of the formation of localities of different concentration either in layers or in the neighbourhood of the crystal. Cautious rocking of the whole thermostat is the limit of disturbance permissible on account of the liability of the crystal to escape from the field of vision, with consequent failure of the experiment. To detect possible errors due to the above-mentioned changes, two pairs of observations of incipient solution and healing temperatures have, when possible, been made with any one solution, and since the results have been found to agree within the limits of the experimental error, the mean of the two pairs of readings is taken as the saturation temperature.

Preliminary experiments were carried out with solutions having saturation temperatures lying between 59° and 62°, but owing to the slow rates of solution and growth at these temperatures, extremely long periods of watching were required, there was a wide interval between the observed incipient erosion and healing temperatures, and the results are somewhat irregular. It was, therefore, decided to limit the experiments to temperatures higher than 64°.

Table III contains a complete record of all the results except those of the above-mentioned tentative experiments and those that gave no reliable result on account of breakdown of the thermocouple or other obvious accident.

FIG. 3.

The solutions are arranged in order of concentration. The letters in the first column give the order in which the solutions were prepared and investigated. The missing letters refer to solutions which gave no result for one or other of the reasons stated above. The numerals in brackets beside the actual temperature readings record the length of time in hours for which the solution had been in the cell when the reading was taken. The final percentage of sucrose inverted, estimated as described later, is recorded in the last column. The remainder of the table is self-explanatory.

Fig. 3 is a graphic record of the results collected in Table III. The broken line represents the smoothed curve of best fit, calculated by the method of least mean squares, on the assumption that the

1682 *The Solubility at High Temperatures of Pure Sucrose in Water.*

concentrations are correct to the third decimal place. The mean of two determinations of saturation temperature for one and the same solution is given the same weight in the calculation as the single determination in the case of the other solutions.

The equation for the curve is $C = 63.608 + 0.1322t + 0.00722t^2$, where C is the concentration in g. of sucrose per 100 g. of solution and t is the saturation temperature ($^{\circ}\text{C}.$). The calculated probable error of observation is $\pm 0.053^{\circ}$ in the sense that the chances that the error is greater or less than the true value are even. This error is of the same order as the observed uncertainty in the reading of the millivoltmeter.

The readings in Table III, recording saturation temperatures at different times for any one solution, show that any progressive change such as inversion or possible evaporation during the observations has had no appreciable effect on the saturation temperature. Also, different solutions of approximately the same initial concentration give closely concordant values.

TABLE IV.

Saturation concentrations of aqueous solutions of pure sucrose from 64° to 82°, in g. per 100 g. of solution.

Temp.	Herzfeld.	Grut.	Taylor.	Temp.	Herzfeld.	Grut.	Taylor.
64°	74.98	75.41	75.026	74°	77.06	77.71	77.345
65	75.18	75.64	75.251	75	77.27	77.95	77.584
66	75.38	75.86	75.478	76	77.48	78.18	77.825
67	75.59	76.09	75.706	77	77.70	78.42	78.068
68	75.80	76.31	75.936	78	77.92	78.66	78.312
69	76.01	76.54	76.168	79	78.14	78.90	78.558
70	76.22	76.78	76.400	80	78.36	79.15	78.805
71	76.43	77.01	76.634	81	78.58	—	79.053
72	76.64	77.24	76.869	82	78.80	—	79.305
73	76.85	77.47	77.106				

A final control determination of the concentration is impracticable on account of the small size of the cell, the fact that the stopper dips deeply into the viscous solution, and the necessity of removing the stopper before the solution is uniformly cold. Nevertheless, the percentage of sucrose inverted is not affected by evaporation occurring after opening the cell and is determined, after suitable dilution, by refractometer and polarimeter readings. Where inversion is very small the result has been checked by means of de Whalley's colorimetric method (*Intern. Sugar J.*, 1937, **39**, 300; 1944, **46**, 211).

This method has the advantage over methods hitherto described (see below) that the concentration is accurately known and, as the results show, is maintained appreciably constant till the readings are complete. Exposure to the atmosphere occurs only on transfer of the solution to the experimental cell, after accurate cooling to the dew point which, in the absence of crystals, presents no difficulty.

Table IV records saturation concentrations for whole degrees calculated from the equation of the smoothed curve. For purposes of comparison the corresponding saturation concentrations given by Herzfeld and by Grut (*loc. cit.*) are also included. All weights are uncorrected for buoyancy. Herzfeld's equation was $C = 64.1835 + 0.13477t + 0.0005307t^2$ (no probable error given), and calculation shows that his curve would cut ours at 62° . Grut did not suggest an equation.

Discussion.—Herzfeld's equation is undoubtedly distorted by the fact that after a solution had been heated for a long period at 90 — 100° , he determined the saturation concentration of the solution at *ca.* 100° solely by a polarimeter reading. Also, he took no measurements between that temperature and 60° . Experiments in this laboratory have shown that at temperatures exceeding 85° inversion becomes rapid even in a vacuum, and the process is hastened by the presence of air. Consequently, the actual concentration in the above experiments of Herzfeld must have been considerably higher than that indicated by the polarimeter on the assumption that the percentage of invert present was negligible. Grut (*loc. cit.*), on the other hand, gives no satisfactory indication as to how he attacked the problem of loss of water by evaporation. It is, therefore, probable that Herzfeld's saturation concentrations above 60° are too low and Grut's too high. Our values fall between the two. Inspection of Table IV shows that in the concentration region of 78 – 80% , Herzfeld's saturation temperatures are about 2° higher than ours and Grut's about $1\frac{1}{2}^{\circ}$ lower.

There is some confirmation of the validity of our equation in a determination of the solubility of sucrose at 25° by Scatchard, Hamer, and Wood (*J. Amer. Chem. Soc.*, 1938, **60**, 3061), who used an isopiestic method which appears to be extremely accurate as far as temperature measurement is concerned, though the method of drying otherwise pure sucrose is less reliable than the standard method used by us. Nevertheless, the recorded solubility of 67.44 g. of sucrose per 100 g. of solution (corrected for buoyancy) is probably more accurate than any other practically determined value, and it agrees remarkably with the extrapolated value of 67.357% at 25° calculated from our equation, and corrected in this example for buoyancy. If there were error appreciably greater than the calculated probable error in our results, extrapolation should expose it.

In conclusion, it may be pointed out that any method which tends to increase the accuracy of the determination of saturation concentrations is important for the calculation of other thermodynamic relationships. For example, Williamson (*Trans. Faraday Soc.*, 1944, **40**, 435, eqn. 34) has introduced the quantity $(dm/dt)_{\text{sat}}$, where m = mols. of sucrose/1000 g. of water, into an exact equation for the calculation of heats of solution. This quantity is immediately obtained, for any given value of t , from our equation by substitution for C in terms of m and differentiation.

My thanks are due to Mr. Philip Lyle, of Messrs. Tate and Lyle, Ltd., for arranging that this work shall be submitted for publication, to Professor W. E. Garner, C.B.E., F.R.S., for suggesting the method and for helpful advice, and also to Miss Marjorie J. Littleton, B.A., for calculating the equation for the smoothed curve and the probable mean error of the experiment.

This work has been carried out by arrangement with the Ministry of Food, Sugar Division.

336. *Experiments on the Synthesis of Cyanomaclurin.*

By ERIC L. FONSEKA.

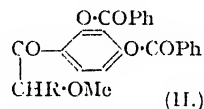

ω -Methoxy-2 : 4-dibenzoylresacetophenone (II, R = H) does not undergo the Mannich reaction, thereby excluding a proposed synthesis of the cyanomaclurin nucleus from (I, R = $\text{CH}_2\cdot\text{NEt}_3$) and phloroglucinol. Catalytic reduction of the flavylum salt (III, R = H) apparently to the flaven (IV, R = H), indicated an alternative route, but the hydrogenation product of O-5 : 2' : 4'-tribenzoyl-O-3-methylmorinidin chloride (III, R = O-COPh), which resembled cyanomaclurin in its colour reactions, could not be recrystallised.

IN the course of experiments on the synthesis of cyanomaclurin (I) (see also Bhalla and Rây, *J.*, 1933, 288; Mitter and Saha, *J. Indian Chem. Soc.*, 1934, **11**, 257; Mitter and Maitra, *ibid.*, 1936, **13**, 236), attempts have been made to prepare a Mannich base, e.g. (II, R = $\text{CH}_2\cdot\text{NEt}_3$), which, on condensation with phloroglucinol, would be expected to give a cyanomaclurin derivative. Despite the use of a wide variety of conditions, ω -methoxy-2 : 4-dibenzoylresacetophenone (II, R = H) failed, however, to undergo the Mannich reaction.

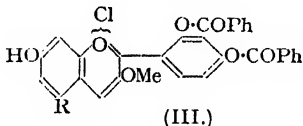

An alternative route was therefore examined, depending on the catalytic reduction of an appropriate flavylum salt. In order to explore the method, experiments were first carried out with 7-hydroxy-2' : 4'-dibenzoyloxy-3-methoxyflavylum chloride (III, R = H), which was

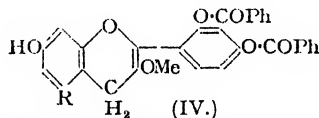

(I.)

(II.)

(III.)

(IV.)

prepared from β -resorcyraldehyde, ω -methoxy-2 : 4-dibenzoylresacetophenone (II, R = H), and hydrogen chloride in ethyl acetate solution. Reduction in acetic acid in presence of Willstätter's platinum catalyst gave a product analysing as a *sesquihydrate* of the flaven (IV, R = H), and showing with alkali and with concentrated sulphuric acid the colour reactions associated with the cyanomaclurin nucleus.

Similarly, the condensation of 2-benzoylphloroglucinaldehyde with (II, R = H) gave the well-defined O-5 : 2' : 4'-tribenzoyl-O-3-methylmorinidin chloride (III, R = O-COPh), which also absorbed two mols. of hydrogen on catalytic reduction. The crude substance likewise exhibited the colour reactions of cyanomaclurin, but all attempts to recrystallise the product for analysis were unsuccessful.

EXPERIMENTAL.

ω -Methoxy-2 : 4-dibenzoylresacetophenone (II, R = H).—Recrystallised ω -methoxyresacetophenone (Slater and Stephen, *J.*, 1920, 312) (13.2 g.) was dissolved in pyridine (65 c.c., redistilled over potassium hydroxide) and the solution cooled in ice while pure benzoyl chloride (24.5 g.) was added with vigorous stirring during 20 minutes. Stirring was continued for $\frac{1}{2}$ hour longer, by which time the smell of benzoyl chloride had practically disappeared, and the mixture left over-night. It was then poured on a mixture

of crushed ice and dilute sulphuric acid, with stirring all the time; a lemon-yellow oil separated, which gradually grew more viscous and finally solidified. The solid was collected, and washed first with cold diluted sulphuric acid and then with water. Recrystallised twice from alcohol, the *dibenzoate* (25 g.) separated in flat needles, m. p. 74–75°, which gave no reaction with ferric chloride (Found, after drying over calcium chloride in a vacuum desiccator: C, 70.8; H, 4.5. $C_{22}H_{18}O_6$ requires C, 70.8; H, 4.6%).

7-Hydroxy-2': 4'-dibenzoyloxy-3-methoxyflavylum Chloride (III, R = H).—Well-dried ω -methoxy-2: 4-dibenzoylresacetophenone (1.18 g.) was dissolved in dry ethyl acetate (30 c.c.). Resorcyaldehyde (0.63 g., dried in a vacuum over sulphuric acid) was added and the mixture warmed to complete solution. The clear liquid was cooled in ice and saturated with dry hydrogen chloride for 2 hours, care being taken to prevent access of moisture. A deep orange-red solution was obtained which was left in a tightly corked flask in the ice chest for 2 days. The *flavylum* salt separated as a red solid which crystallised from hot glacial acetic acid in flat, rectangular, orange prisms (Found, in air-dried substance: C, 62.1; H, 4.4; Cl, 6.2; OMe, 5.4. $C_{30}H_{24}O_7Cl_3 \cdot 3H_2O$ requires C, 61.8; H, 4.6; Cl, 6.1; OMe, 5.3%).

7-Hydroxy-2': 4'-dibenzoyloxy-3-methoxyflaven (IV, R = H).—The *flavylum* salt (1 g.) dissolved in glacial acetic acid (160 c.c.) was placed in a hydrogenation flask with the platinum catalyst (0.1 g.). The absorption of hydrogen, which was fairly rapid up to 35 c.c., slowed down considerably and after 24 hours reached 45 c.c. (2H requires 36 c.c.), while the deep orange-red solution turned light brown. The reduced solution was diluted with a large quantity of ether and the ethereal extract, after being washed with ice water, sodium bicarbonate solution, and then again with ice water, was dried ($CaCl_2$) and the ether removed under reduced pressure at room temperature. A faintly pink solid was obtained which, after repeated precipitations with dry petrol from an ethereal solution, was crystallised from a mixture of these two solvents. The crystals were faintly yellow, and on treatment with sodium hydroxide in the cold gave a blue dichroic solution which turned green on standing. With concentrated sulphuric acid, a claret-red solution was obtained (Found, in substance dried in a vacuum over calcium chloride: C, 69.0; H, 4.6. $C_{30}H_{24}O_7 \cdot 1.5H_2O$ requires C, 69.2; H, 4.7%).

O-5: 2': 4'-tribenzoyl-O-3-methylmorinidin Chloride (III, R = O-COPh).—Pure dry ω -methoxy-2: 4-dibenzoylresacetophenone (5 g.) was dissolved in dry ethyl acetate (100 c.c.), and 2-benzoylphloroglucinaldehyde (3.2 g.) added. The mixture was warmed to ensure complete solution and filtered. The clear solution, cooled in ice, was saturated with dry hydrogen chloride for 3 hours. A small quantity of the sparingly soluble benzoylphloroglucinaldehyde separated and was removed. The clear deep red solution was left in the ice chest for 3 days, but no *flavylum* salt separated. It was then poured into dry ether, and the solid which separated was collected and washed with dry ether. The *salt* was deep red with a green reflex; unlike the resorcinol analogue it was readily soluble in glacial acetic acid. It was crystallised from methyl cyanide, separating in flat orange rectangular plates (Found, in substance dried over sulphuric acid: C, 66.6; H, 3.82; Cl, 5.1. $C_{27}H_{22}O_9Cl_3 \cdot H_2O$ requires C, 66.6; H, 4.05; Cl, 5.3%).

The *flavylum* salt (1 g.) was dissolved in glacial acetic acid (60 c.c.), Willstätter's platinum catalyst (0.1 g.) added, and the solution shaken with hydrogen. The quantity of hydrogen taken up was 34 c.c. (2H requires 34 c.c.). The solution changed in colour from dark orange-red to light brownish-red which darkened considerably in contact with air. It was quickly filtered into ice-water, and the faintly pink solid collected, washed with water, and dried in a vacuum over calcium chloride. In dilute sodium hydroxide solution a faint green colour was observed, which on heating became bright blue, while concentrated sulphuric acid dissolved it to yield a crimson solution.

The author expresses his thanks to Sir Robert Robinson, P.R.S., for advice and encouragement during the course of this work.

[Received, November 15th, 1946.]

337. The Synthesis of β -6-Methoxyquinolyl(4)ethylamine, β -6-Methoxyquinolyl(4)propionamidine, and β -6-Methoxyquinolyl(4)ethylguanidine.

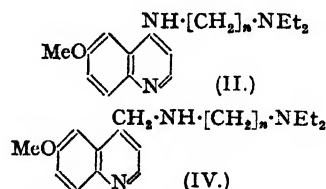

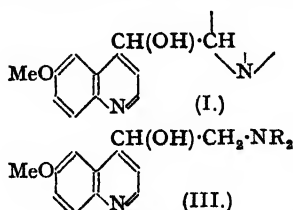

By JAMES WALKER.

β -6-Methoxyquinolyl(4)-ethylamine, -propionamidine, and -ethylguanidine have been synthesized. In common with quinine, each possesses a strongly basic group separated by a chain of two carbon atoms from the 4-position of 6-methoxyquinoline. The substances were devoid of antimalarial activity.

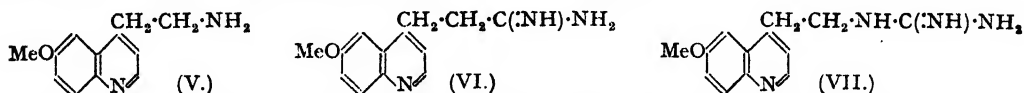

In quinine, the significance of which in the chemotherapy of malaria requires no emphasis, one finds that a strongly basic group is separated from the 4-position of 6-methoxyquinoline by a chain of two carbon atoms as shown in the partial formula (I), where details of the quinuclidine ring system are omitted for the sake of clarity.

Although Giemsa and Oesterlin (*Arch. Schiffs- u. Tropen-Hygiene*, 1933, **37**, Beiheft 4), in studying numerous modifications of the quinine molecule, have attached considerable significance to the alcoholic hydroxyl group, and its replacement in the cinchona alkaloids by chlorine results in loss of antimalarial activity (Cohen and King, *Proc. Roy. Soc.*, 1938, **B**, **125**, 49), the prime necessity for the carbinol group appears to be discounted by the activity of 4- ω -dialkylaminoalkyl-amino-6-methoxyquinolines (II) (Magidson and Rubtsov, *J. Gen. Chem. Russia*, 1937, **7**, 1896) in

avian malaria. King and his colleagues (*Proc. Roy. Soc.*, 1938, B, 125, 60; *J.*, 1940, 1307) have shown that some latitude is possible with the quinuclidine half of the quinine molecule by demon-

strating antimalarial activity in certain carbinolamines of type (III; R = alkyl), thus inviting comparison of types (II) and (III). Interposing a methylene group between the quinoline ring in (II) and the proximate nitrogen atom of the aliphatic diamine group, giving substances of type (IV), has been shown to have a dystherapeutic effect (Schönhöfer, "Medicine in its Chemical Aspects," 1938, 8, 66; Work, *J.*, 1942, 426). Assuming, in line with current thought regarding the mode of action of drugs, that the antimalarial activity of quinine is due to its interference with the function of an essential structure in the parasite, it is likely that the two basic groups play a large part in the reaction and, if it is due to multipoint fit on a protein, the distance separating the basic centres should be significant. The three bases, β -6-methoxyquinolyl(4)-ethylamine (V), -propionamidine (VI), and -ethylguanidine (VII) were therefore synthesized since, in common with quinine, each possesses a strongly basic group separated by a chain of two carbon atoms from the 4-position of 6-methoxyquinoline.

Condensation of 6-methoxyepidrine with chloral was most advantageously carried out by heating them together at 120° in the presence of a little xylene as a flux. The use of pyridine as solvent at water-bath temperature (Alberts and Bachman, *J. Amer. Chem. Soc.*, 1935, 57, 1284; Clemons and Hoggarth, *J.*, 1939, 1242) was much less satisfactory, the methoxyl group in the 6-position appearing to reduce significantly the reactivity of the methyl group in the other nucleus. Hydrolysis of the resulting $\alpha\alpha\alpha$ -trichloro- β -hydroxy- γ -6-methoxyquinolyl(4)propane (VIII) afforded β -6-methoxyquinolyl(4)acrylic acid (IX), which was also obtained in less satisfactory over-all yield from 6-methoxyquinoline-4-aldehyde and malonic acid. Notwithstanding the use of freshly prepared selenium dioxide (Kaplan, *J. Amer. Chem. Soc.*, 1941, 63, 2654) for the preparation of 6-methoxyquinoline-4-aldehyde, $\alpha\beta$ -bis-6-methoxyquinolyl(4)ethylene (X), together with quininic acid, was formed in considerable amount during the oxidation of 6-methoxyepidrine, indicating the formation of this type of compound not to be attributable solely to ageing of the selenium dioxide used in the oxidation. Hydrogenation of the unsaturated acid (IX) afforded β -6-methoxyquinolyl(4)propionic acid (XI), which was converted through the methyl ester into the hydrazide, from which the amine (V), characterised as the dihydrochloride, was obtained in good yield by Naegeli's modification (*Helv. Chim. Acta*, 1929, 12, 227) of the Curtius degradation. The acid (XI) was also converted through the amide into the nitrile from which the amidine (VI), characterised as the nitrate and as the benzoate, was prepared by the orthodox Pinner method. When 6-methoxyquinolylethylamine (V) was liberated from the dihydrochloride in concentrated aqueous solution with the calculated volume of standard alkali and refluxed with *S*-methylisothiurea sulphate in the usual way, an indifferent yield of the required guanidine (VII) was obtained and the product was difficult to purify. An excellent method, however, was found to be the interaction of the amine (V) dihydrochloride with *S*-methylisothiurea sulphate in concentrated aqueous ammonia at room temperature, the crude guanidine (VII) sulphate readily separating. This seemingly unorthodox technique has previously been used for the conversion of amino-acids into guanidino-acids (D.R.-P. 535,070; Schütte, *Z. physiol. Chem.*, 1943, 279, 52) and is presumably applicable generally to primary and secondary amines which are stronger bases than ammonia, so that the ammonia, present in large excess, competes at a disadvantage with a more powerful nucleophilic reagent for the *S*-methylisothiurea. The guanidine (VII) was characterised as the nitrate.

Tests for therapeutic activity in *P. relictum* infections in canaries were kindly carried out by Dr. Ann Bishop at the Molteno Institute, Cambridge, on (V) (dihydrochloride) and (VI) (nitrate). Miss I. M. Tonkin kindly tested (V) (dihydrochloride), (VI) (nitrate and benzoate), and (VII)

(nitrate) for therapeutic activity in *P. gallinaceum* infections in chicks. No antimalarial action was observed.

EXPERIMENTAL.

6-Methoxylepidine.—The following reduction of 2-chloro-6-methoxylepidine is an improvement on previously described procedures. The chloro-compound (100 g.) (Ainley and King, *Proc. Roy. Soc.*, 1938, B, 125, 60) in alcohol (750 c.c.) containing aqueous sodium hydroxide [23 g. (20% excess) in 75 c.c.] was vigorously stirred (mercury seal) in an atmosphere of hydrogen in the presence of palladised strontium carbonate (9 g.), the vessel being kept in a bath at 50–55° throughout. The anticipated volume of hydrogen was absorbed in a few hours, and the alcohol was removed by distillation from the filtered solution. The crude product was taken up in excess of 2N-sulphuric acid, filtered from any unreduced material, and the reduction product was liberated by careful addition, with stirring, of 40% aqueous sodium hydroxide. The precipitated oil quickly crystallised, affording 6-methoxylepidine monohydrate (88.2 g.; 96%), m. p. 52°.

aaa-Trichloro- β -hydroxy- γ -6-methoxyquinolyl(4)propane (VIII).—6-Methoxylepidine monohydrate (108.7 g.) was dehydrated by exhaustive azeotropic distillation with benzene and then mixed with anhydrous chloral (125 g.; 1½ mols.) and xylene (15 c.c.) which served as a flux. The mixture was heated at 118–120° for 15 hours, becoming solid during the process. The product crystallised from alcohol in colourless rectangular plates (165 g.; 91%), m. p. 196–197° (Found: C, 48.5; H, 4.1; Cl, 33.4. $C_{13}H_{11}O_3NCl_3$ requires C, 48.7; H, 3.7; Cl, 33.2%).

The final mother-liquors were treated in the manner described below with potassium hydroxide to convert any remaining chloral-methoxylepidine into the acrylic acid, but only a small amount (7.5 g.) of unchanged 6-methoxylepidine was recovered.

β -6-Methoxyquinolyl(4)acrylic Acid (IX).—(A) The above chloral-methoxylepidine (146.5 g.) was added in portions to a solution of potassium hydroxide (146 g.) in absolute alcohol (600 c.c.) which was heated and stirred on the water-bath. A vigorous reaction took place after each addition, and finally the mixture was left for one hour on the water-bath. The precipitated potassium chloride was removed and washed with spirit. The alcoholic solution and washings, diluted with an equal volume of water, were concentrated under reduced pressure on the water-bath to remove alcohol. The aqueous solution, treated with norite, afforded, on acidification with glacial acetic acid, a yellow precipitate of the acrylic acid monohydrate (89 g.; 79%). The acid separated from 90% acetic acid in pale yellow fine needles which showed an intense yellow fluorescence in ultra-violet light, m. p. 277–278° (Found: C, 62.9; H, 5.2; loss at 110° in a vacuum, 7.8. Found, for anhydrous material: C, 67.5; H, 4.8. $C_{13}H_{11}O_3N \cdot H_2O$ requires C, 63.2; H, 5.2; H_2O , 7.3. $C_{13}H_{11}O_3N$ requires C, 68.1; H, 4.8%).

(B) 6-Methoxyquinoline-4-aldehyde (29.3 g.) (Kwartler and Lindwall, *J. Amer. Chem. Soc.*, 1937, 59, 524) and malonic acid (37.5 g.) were condensed in pyridine (72 c.c.) containing piperidine (2 c.c.) on the water-bath for 3 hours and finally under reflux for ¼ hour. The product was isolated in the usual way and purified by reprecipitation from solution in excess of aqueous sodium hydroxide and recrystallisation from 90% acetic acid (yield, 25.3 g.; 65%), m. p. 277°.

$\alpha\beta$ -Bis-6-methoxyquinolyl(4)ethylene (X).—The selenium-containing residues from the oxidation of 6-methoxylepidine in dioxan (Kaplan's conditions, *loc. cit.*) were extracted with hot pyridine. The hot solution was treated with norite and cooled, whereupon a solid separated. The solid was extracted with chloroform, and quininic acid remained undissolved, m. p. after recrystallisation from nitrobenzene, 279–280° (Found: C, 65.0; H, 4.2. Calc. for $C_{11}H_9O_3N$: C, 65.0; H, 4.4%). The reddish-orange chloroform extract was filtered through alumina, affording a clear orange solution with a strong greenish-blue fluorescence. Evaporation to dryness and recrystallisation of the residue from ethyl acetate afforded fine yellow prisms of the *ethylene*, m. p. 195–196° [Found: C, 76.6; H, 5.4; N, 8.4; *M* (Rast), 368. $C_{22}H_{19}O_6N_2$ requires C, 77.2; H, 5.3; N, 8.2%; *M*, 342].

β -6-Methoxyquinolyl(4)propionic Acid (XI).—The above acrylic acid (IX) (25.3 g.) was dissolved in a slight excess of 2N-aqueous sodium hydroxide and shaken in an atmosphere of hydrogen in the presence of palladised strontium carbonate (7 g.). The theoretical volume of hydrogen was readily absorbed (in 3 hours) and no further absorption took place on continued shaking (for 1 hour). The product (24.3 g.) was isolated in the usual way. The acid separated from 30% aqueous acetic acid in fine colourless prisms, m. p. 225–226° (Found: C, 67.2; H, 5.6. $C_{13}H_{13}O_3N$ requires C, 67.5; H, 5.6%). The solid and its solution in aqueous acetic acid both showed an intense bluish-white fluorescence in ultra-violet light.

The *methyl ester* (24.9 g.) was obtained by refluxing the acid (25 g.) with methanol (150 c.c.) and concentrated sulphuric acid (9 c.c.) for 8 hours. It was isolated in the normal way, and separated from ligroin containing a little benzene in colourless rectangular prisms, m. p. 90° (Found: C, 68.3; H, 5.9. $C_{14}H_{15}O_3N$ requires C, 68.6; H, 6.1%).

The *amide*, obtained by treating the methyl ester (24.9 g.) in methyl alcohol (50 c.c.) with excess of concentrated aqueous ammonia (300 c.c.) at 37° for 5 days, separated from water in colourless needles (19.6 g.), m. p. 187–188° (Found: C, 67.5; H, 6.0; N, 12.2. $C_{13}H_{14}O_2N_2$ requires C, 67.8; H, 6.1; N, 12.2%).

The *hydrazide*, obtained by refluxing the methyl ester (29.2 g.) with a slight excess of 50% hydrazine hydrate in methyl alcohol (70 c.c.) for 5 hours, separated from spirit in minute colourless prisms (28 g.), m. p. 161–162° (Found: C, 63.2; H, 6.0; N, 16.8. $C_{13}H_{15}O_2N_3$ requires C, 63.7; H, 6.1; N, 17.1%).

β -6-Methoxyquinolyl(4)propionitrile.—The above amide (5.5 g.) was refluxed with phosphorus oxychloride (6 c.c.) in dry chloroform (20 c.c.) for 25 minutes, the solid rapidly dissolving. Solvent and excess of phosphorus oxychloride were removed in a vacuum on the water-bath and the residue was distributed between ether and ice-cold aqueous alkali. The ethereal solution was dried over sodium sulphate and evaporated, the desiccant being washed with acetone to recover some of the product which crystallised out, and the thick colourless syrup (4.9 g.) promptly crystallised on removal of the solvent.

The *nitrile* separated from benzene-ligroin (*ca.* 1 : 1) in clusters of transparent, colourless, rectangular prisms, *m. p.* 96–97° (Found : N, 13.3. $C_{13}H_{12}ON_2$ requires N, 13.2%).

β-6-Methoxyquinolyl(4)propionamidine (VI) *Nitrate*.—A solution of the above nitrile (6.66 g.) in a mixture of absolute alcohol (15 c.c.) and dioxan (15 c.c.) was saturated with hydrogen chloride at 0° and kept in the ice-chest for several days. The solvent and excess of hydrogen chloride were removed at room temperature in a vacuum and the residue was warmed at 37° with 10% alcoholic ammonia (90 c.c.) for a week. The small amount of ammonium chloride was rejected and the filtered solution, on evaporation to dryness, afforded a crude hydrochloride (7.7 g.) which could not be satisfactorily crystallised. The main bulk of the product was dissolved in a small volume of water and treated with a similar solution of an equal weight of ammonium nitrate, and the mixture was evaporated to dryness. The *nitrate* crystallised from about 1½ times its own weight of water in clusters of fine colourless needles, *m. p.* 190–191° (decomp.) (Found : C, 53.3; H, 5.5; N, 18.6. $C_{13}H_{12}ON_3 \cdot HNO_3$ requires C, 53.4; H, 5.5; N, 19.2%).

β-6-Methoxyquinolyl(4)propionamidine *Benzoate*.—The crude amidine hydrochloride, prepared from the nitrile (7.2 g.) as described above, was dissolved in a small volume of water and treated with a slight excess of sodium benzoate in concentrated aqueous solution. The precipitated *benzoate* (11.3 g.) separated from about 8 times its own weight of water in colourless prisms, *m. p.* 192° (Found : C, 68.0; H, 6.0; N, 11.9. $C_{13}H_{12}ON_2 \cdot C_7H_5O_2$ requires C, 68.4; H, 6.0; N, 11.9%). The benzoate was much more soluble in spirit than in water.

β-6-Methoxyquinolyl(4)ethylamine (V) *Dihydrochloride*.—The above hydrazide (31.9 g.) was dissolved in 40% aqueous acetic acid (325 c.c.) and cooled below 0° while an aqueous solution (100 c.c.) of sodium nitrite (36 g.) was added dropwise with thorough stirring. The azide quickly separated and the solid was collected after 1½ hours. The filtrate was neutralised to pH 8.5 with solid sodium carbonate and the azide was re-suspended in the slightly alkaline liquor and again collected, washed with water, and dried overnight in a vacuum over phosphoric oxide. The crude *dry* azide was then cautiously warmed in dry benzene (100 c.c.) until reaction set in. After the spontaneous reaction subsided the mixture was refluxed for 20 minutes and cooled. The brown solution was treated with concentrated hydrochloric acid (50 c.c.) and the benzene was removed on the water-bath after the reaction had ceased. Water was added to keep the hydrochloride in solution, and the *dihydrochloride*, obtained after decolourisation with charcoal and evaporation to dryness, separated from 90% alcohol in fine colourless needles (29.7 g.; 83%), *m. p.* 253° (Found : C, 52.7; H, 6.0; N, 10.4. $C_{13}H_{14}ON_2 \cdot 2HCl$ requires C, 52.4; H, 5.8; N, 10.2%).

β-6-Methoxyquinolyl(4)ethylguanidine (VII) *Nitrate*.—The preceding dihydrochloride (3 g.) and *S*-methylisothiurea sulphate (3 g.; 2 equivs.) were dissolved in concentrated aqueous ammonia (35 c.c.) at room temperature and set aside for 42 hours, crystallisation of solid commencing within 2 hours. The crude methoxyquinolylethylguanidine sulphate was collected, washed with a little water, and dried in a vacuum (yield, 2.8 g.); recrystallisation at this stage afforded a somewhat gelatinous product. The reaction mother-liquors were evaporated to dryness and worked up for nitrate (0.11 g.). The crude sulphate (1 g.) was dissolved in hot water (*ca.* 10 c.c.) and treated with a warm aqueous solution (2 c.c.) of ammonium nitrate (2 g.), whereupon the *nitrate* crystallised out. Recrystallisation from a small volume of water afforded colourless clusters of extremely fine felted needles, *m. p.* 239° (decomp.), giving a positive Sakaguchi reaction (Found : C, 50.6; H, 5.7; N, 22.5. $C_{13}H_{14}ON_4 \cdot HNO_3$ requires C, 50.8; H, 5.6; N, 22.8%). The over-all yield of the nitrate was 70%.

When the foregoing reaction was carried out in hot aqueous solution, using (in the order of mixing) 1 mol. of amine dihydrochloride, 2 mols. of sodium hydroxide, and 1 equiv. of *S*-methylisothiurea sulphate, the yield and quality of the product were markedly inferior.

The author is greatly indebted to Dr. Ann Bishop and to Miss I. M. Tonkin, B.Sc., for kindly carrying out the antimalarial tests, and to Mr. L. V. Sharp for assistance in the preparation of starting materials.

338. *Hydrated Oxalates of Some Rare-earth Elements.*

By A. W. WYLIE.

The preparation of the "interstitial hydrates" of some cerium-group oxalates and of yttrium oxalate is described. A 6-hydrate and a 2-hydrate of lanthanum oxalate and a 2-hydrate of yttrium oxalate have been prepared. Some properties of these compounds, including optical properties, have been studied, and the structure of the hydrates discussed.

ALTHOUGH numerous hydrates of the rare-earth oxalates have been reported in the literature (Beilstein, "Handbuch der Organischen Chemie", 4th edtn.), confusion persists as to the identity of many of them. Further information about these compounds seems desirable in view of their importance in the chemistry of the rare-earth elements.

It was shown by Löwenstein (*Z. anorg. Chem.*, 1909, 63, 69, 113) that oxalates of lanthanum, cerium, and yttrium containing between 9 and 12 mols. of water per mol. of oxalate varied continuously in composition at a given temperature with the pressure of aqueous vapour. This behaviour is characteristic of a group of hydrates containing what is sometimes termed "zeolitic" water. Although conveniently classing together those hydrates which give a bivalent system

on dehydration, the designation "zeolitic hydrate" is misleading, in that salts such as the rare-earth oxalates of the above-mentioned composition contain none of the interstitial cations present in the natural and synthetic zeolites. Barrer and Ibbitson (*Trans. Faraday Soc.*, 1944, **40**, 195) and Barrer (*Ann. Reports*, 1944, **41**, 31) consider that the state of water and other solutes in the zeolites is best described as an "interstitial solid solution", and since water in the rare-earth oxalates and similar compounds may also be regarded as being in interstitial solid solution, it is proposed to distinguish such compounds as "interstitial hydrates".

The work of Löwenstein and others indicates that substances previously classed as 9-, 10-, and 11-hydrates are to be regarded as interstitial hydrates, to which no definite composition can be attributed, but it is not clear from the literature whether a number of other substances containing considerably more or less water than indicated above are to be included in this category or regarded as separate entities. That the latter alternative is correct is shown subsequently, for the range of composition of interstitial hydrates precipitated from solution and isolated by the usual methods has been found to vary from 9.6 to 10.9 mols. of water per mol. of oxalate.

Well-formed crystals of the interstitial hydrates may readily be obtained by slow precipitation in nitrate solutions at 70°. Chemical and crystallographic evidence shows that these hydrates are identical with an isomorphous series of 11-hydrates described by Wyrnuboff (*Bull. Soc. franç. Min.*, 1901, **24**, 105, 111; 1902, **25**, 66). Identification is most readily made by optical methods owing to variable development of crystal faces and a tendency to adopt different habits according to the mode of preparation.

Conditions for the precipitation of the interstitial hydrates differ from one oxalate to another. For instance, in 3% nitric acid the cerium compound is obtained at temperatures between 0° and 100°. The lanthanum and the yttrium compound, however, are formed only below 80°, 6-hydrates being obtained at higher temperatures. Although lanthanum forms the interstitial hydrate at 0°, yttrium forms a 17- or higher hydrate below 15°. "Didymium" oxalate and the mixed rare-earth oxalates in which cerium predominates resemble the pure cerium compound in behaviour.

The isolation of a 6-hydrate of lanthanum oxalate raises the question of analogous cerium-group oxalates, though no such compounds could be prepared. Since the 6-hydrates of both lanthanum and yttrium oxalate appear to form 2-hydrates on heating, formation of the latter type of hydrate may be general in the case of the 6-hydrates of the yttrium-group oxalates prepared by Marsh (*J.*, 1944, **40**). No 17-hydrate other than $\text{Y}_2(\text{C}_2\text{O}_4)_3 \cdot 17\text{H}_2\text{O}$ (Brauner, *J.*, 1898, **73**, 951; Marsh, *loc. cit.*) has been reported for oxalates of the rare earths, but in view of the behaviour of the so-called 17-hydrate either alone or when mixed with other hydrates, it is possible that a similar or higher hydrate was present in the material described by Wirth (*Z. anorg. Chem.*, 1912, **76**, 174) as a 14-hydrate of erbium oxalate. The degree of hydration of such compounds is unusually high for oxalates.

Properties of the Interstitial Hydrates.—Preservation of crystal form and transparency after dehydration is characteristic of this class of hydrate. Density measurements on the cerous compound reveal that dehydration is accompanied by a volume contraction exceeding 27%. The observation that certain inter-edge angles change markedly upon dehydration while other inter-edge angles remain almost unchanged suggests that contraction parallel to the (010) plane exceeds that in other directions. This contention is supported by cleavage of many dehydrated crystals parallel to the (010) plane.

Rapid yet incomplete expulsion of water from these crystals on heating, and resorption of water vapour at lower temperatures by the partly hydrated substances, indicates that transference of water to and from the crystal lattice is readily reversible in the early stages of dehydration. Very slow escape of residual water and similar slow resorption of water vapour by a sufficiently dehydrated product may be attributed to contraction of the interstitial channels. The sorption-desorption mechanism under either of these conditions possibly follows the process of activated diffusion visualised for the natural zeolites by Emmett and De Witt (*J. Amer. Chem. Soc.*, 1943, **65**, 1253) and by Barrer (*Trans. Faraday Soc.*, 1944, **40**, 206, 555). This contrasts with the simpler and more speedy diffusion process operative when the diameter of the channel exceeds the effective diameter of the solute molecules.

The action of water on the partly dehydrated oxalates varies with the extent of dehydration. If this is sufficient to cause extensive changes in the lattice *viz.*, greater than about 90% in the cerium-group oxalates and greater than about 70% in yttrium oxalate, less energy is required to move ions from the lattice to the solution than is involved in transferring a water molecule from solution to an appropriate position in the crystal; solution effects therefore predominate

over sorption effects. An immediate consequence of the entry of ions into solution is the deposition of the fully hydrated interstitial hydrate, which is the appropriate solid phase at the temperature of the system. If the extent of dehydration and lattice rearrangement is less, lattice forces are sufficiently strong to prevent escape of ions and sorption of water by the lattice predominates.

Conversion of rare-earth oxalates into "hydroxides" is usually accomplished by boiling with sodium hydroxide. It has been found that reaction with the interstitial hydrate proceeds rapidly in cold 15% sodium hydroxide. With suitable crystals migration of the phase boundary between newly-formed "hydroxide" and residual crystalline hydrate can readily be followed under the microscope. Initially the process is assumed to involve transfer of hydroxyl and oxalate ions across the ingoing surface:

Since the product appears to be non-crystalline when examined in visible light, possessing only a "relic" structure, it is further assumed that subsequent rearrangement of cerous and hydroxyl ions and of interstitial water molecules occurs, leading to formation of a hydrous oxide or hydroxide of cerium in a gelatinous or microcrystalline condition.

By ignition of the interstitial hydrates in air at 900°, particles of oxides are formed which still retain the sharp outlines of the original hydrate crystals (cf. Urie and Wylie, *J. Soc. Chem. Ind.*, in the press). The channels in the dehydrated oxalate crystal must therefore be sufficiently wide to allow decomposition products of the oxalate radical to escape without disintegration of the structure. Furthermore, the mobility of the anions and cations of the residual oxide must be small at 900°, though sufficient at 1200° to bring about collapse of the relic structure and relatively speedy formation of a thermally stable form of oxide.

Limiting Composition and Structure of Interstitial Hydrates.—The highest values found in this investigation for the molar ratio of water in the lanthanum and cerium hydrates approach 11, a value found by James and Robinson (*J. Amer. Chem. Soc.*, 1913, **35**, 754) for pure neodymium oxalate at 25° in water and solutions of neodymium nitrate. For yttrium oxalate this molar ratio approaches 10 in samples known to be homogeneous. No study of the composition of this solid in contact with water or aqueous solutions has been reported. If the interstitial hydrates were strictly isomorphous, the number of interstitial positions available to water molecules should be the same in each hydrate and the maximum molar ratio should be 11 for oxalates of both the cerium and the yttrium group. Yttrium oxalate, however, differs in a number of respects from the cerium-group oxalates and strict isomorphism cannot be assumed. These differences must ultimately be traced to differences in the ionic radii and polarisabilities of the cations.

Since James and Robinson found that the "11-hydrate" of neodymium oxalate behaved as a definite compound it must be assumed, in order to reconcile this result with the properties of the solid interstitial hydrates, that the substance $\text{M}_2(\text{C}_2\text{O}_4)_3 \cdot 11\text{H}_2\text{O}$ (where M is a rare-earth element) forms a continuous series of solid solutions with its dehydration products. This interpretation requires that the *p-c* isotherms of the system oxalate-water vapour should extrapolate to the same composition for the interstitial hydrates of lanthanum, cerium, and neodymium. As the curves obtained by Löwenstein (*loc. cit.*) show little indication of behaving in this fashion at 25°, it is assumed that the systems investigated were not in equilibrium. It seems doubtful if the curve given for erbium oxalate was obtained with homogeneous material.

No X-ray determination of the crystal structures of rare-earth oxalates has been made. It is assumed that water molecules are held in the lattice of the interstitial hydrates in interstices between the cations and the larger oxalate ions, the latter of which have a predominating effect in determining the crystal structure. Forces restraining water molecules in the lattice presumably consist of electrostatic forces (ion-dipole and ion-induced dipole forces) and dispersion forces. In the fully saturated hydrates $\text{M}_2(\text{C}_2\text{O}_4)_3 \cdot 11\text{H}_2\text{O}$ in which all available interstitial positions are occupied by water molecules an ordered arrangement of solute molecules may be assumed, whereas in the partly hydrated substances the distribution of water molecules is assumed to be statistical.

A survey of the optical properties of various forms of oxalic acid and its salts reveals that the great majority of these substances resemble the rare-earth oxalates in forming strongly birefringent monoclinic crystals. This behaviour may largely be attributed to the high refracting power and anisotropy of the oxalate ion (Evans, "Crystal Chemistry", Cambridge Univ. Press, 1939, **24**, 270; Wooster, *Z. Krist.*, 1931, **80**, 495; Robertson, *J.*, 1936, 1817). The optical data appear to exclude the possibility of a layer lattice in the interstitial hydrates. The

almost isotropic character of the crystals formed by expulsion of water from the lanthanum and cerium hydrates may be explained by assuming rotation of planar oxalate ions about a centre until, when 90% or more of the water is expelled, the anions of the lattice consist of oxalate groups inclined in all directions in space. A similar arrangement is not reached in yttrium oxalate owing to decomposition of the oxalate before sufficient water can be expelled to allow the necessary degree of rotation of the anions.

EXPERIMENTAL.

Purity of Materials.—Commercial brands of lanthanum, cerium, and yttrium nitrates "free from other rare earths" were employed as the hexahydrates. *Lanthanum nitrate.* The only impurities detected were phosphate (0.01%) and traces of calcium; the average atomic weight, calculated from the ratio $\text{La}_2\text{O}_3 : 3\text{C}_2\text{O}_4$, was 138.6. *Cerous nitrate.* Traces of phosphate were present; the average atomic weight, calculated from the ratio $2\text{CeCO}_3 : 3\text{C}_2\text{O}_4$, was 140.3. *"Didymium" nitrate.* A salt containing a preponderating amount of neodymium nitrate was used. *Yttrium nitrate.* A 10-cm. thickness of a 2M-solution showed faint absorption lines due to erbium and holmium; the average atomic weight was 89.4 and this value was used in calculating the composition of various hydrates of yttrium oxalate. *Mixed cerium-group nitrates.* These, containing thorium, were prepared from the mixed hydroxides by dissolving them in nitric acid and reducing ceric nitrate by addition of hydrogen peroxide.

Solutions for precipitation were placed in a thermostat, and 10% oxalic acid added in excess unless stated otherwise. The rate of precipitation was varied by controlling the rate of addition of oxalic acid. Products formed at 50° or above were digested in solution for 1 hour before being filtered; below 50° the digestion time was 4 hours. Each hydrate was washed four times with water at the temperature of precipitation, and after treatment with alcohol and ether was dried to constant weight in air and transferred to sealed jars.

All samples were examined under the microscope for homogeneity before analysis.

The oxalate radical was determined by dissolving the compound in warm 10% sulphuric acid and titrating at 80° with 0.1N-potassium permanganate. Oxides were determined by igniting the oxalates to 1000°. Cerium, determined volumetrically by oxidation with ammonium persulphate followed by titration with ferrous ammonium sulphate (tri-*o*-phenanthrolineferrous complex indicator), agreed satisfactorily with results obtained by the ignition method. The oxalate was first brought into solution by heating with ammonium persulphate, sulphuric acid, and silver nitrate (Axt, *J. Soc. Chem. Ind.*, 1941, 60, 229).

Lanthanum Oxalate.—The solutions contained (a) lanthanum nitrate 10 g., 66% nitric acid 3 ml., water 100 ml., and (b) lanthanum nitrate 5 g., 66% nitric acid 3 ml., water 1 l.

Solu- tion.	Temp.	Precipitation time, mins.	Molar ratio of water in product.	Remarks.
a	98—75°	120	6.00 *	Small granular crystals and aggregates
b	50	3	7.5—8.6	Mixture
		60	10.5	Interstitial hydrate,† well-formed crystals
		5	10.5	" " poorly-formed crystals
	20	60	10.4, 10.4	" " globular aggregates
	0	60	10.4, 10.6	" " " "

* Found: La_2O_3 , 50.1, 50.0; C_2O_4 , 40.6, 40.6. $\text{La}_3(\text{C}_2\text{O}_4)_3 \cdot 6\text{H}_2\text{O}$ requires La_2O_3 , 50.1; C_2O_4 , 40.6%.

† Also formed by adding just insufficient oxalic acid to cause precipitation at 75°, and cooling to 20°.

At 180° the hexahydrate appears to form a stable dihydrate [Loss of wt., 11.1—11.3. Required for loss of $4\text{H}_2\text{O}$, 11.1%. Found: C_2O_4 , 45.7. $\text{La}_3(\text{C}_2\text{O}_4)_3 \cdot 2\text{H}_2\text{O}$ requires C_2O_4 , 45.7%].

The interstitial hydrate at 180° rapidly lost up to 85% of its water content. A further 10% was lost very slowly, even in a vacuum, the molar ratio of water in the residue falling to approximately 0.53 after 142 hours without constancy in composition being reached. At 280° the oxalate slowly decomposed. When dehydration was somewhat less than 85% complete, the residues resorbed water when placed in an atmosphere of water vapour at 20°, at first rapidly and then more slowly, resorption being eventually complete. When dehydration was more than 85% complete, reaction with water vapour was very slow, less than 7% of the total water content being resorbed after 100 hours.

When heated with 5.7N-sulphuric acid for 2 days at 25°, the interstitial hydrate formed rectangular, lath-shaped crystals belonging to the orthorhombic or tetragonal system. Although sulphate could not be completely removed by washing with water without decomposing the crystals, the composition approximated to the 7-hydrate described by Brauner and Pavlicek (*J.*, 1902, 81, 1264) and by Wirth (*Z. anorg. Chem.*, 1908, 58, 226).

Cerous Oxalate.—Solutions (a) and (b) were similar in composition to those used for preparation of lanthanum oxalate.

Solu- tion.	Temp.	Precipitation time, hrs.	Molar ratio of water in product.	Remarks.
a	101°	3.5	8.5—9.2	Mixture of interstitial hydrate and lesser amount of small granular crystals
b	98	1	10.3	Interstitial hydrate, well-formed crystals
		2	10.6	" " " "
a	80	1	10.3—10.6	" " " "
	20	1	10.8, 10.9	" " globular aggregates
	0	2	10.9	" " " "

Attempts to prepare a pure 6-hydrate by boiling the interstitial hydrate for 17 hours in water or 1% nitric acid were unsuccessful.

The rates of dehydration of the interstitial hydrate at 180° and of resorption of water vapour at 20° were very similar to the rates observed for the analogous lanthanum hydrate. Prolonged heating in air caused slow formation of a yellow ceric compound, although approximately 92% of the water content could be removed in a vacuum at 180° without decomposition of the oxalate. Rapid oxidation in air occurred at 280°.

The contraction of the interstitial hydrate during dehydration was followed by determining the density of well-formed crystals in bromobenzene at 25° ± 0.01°. This substance is known to be occluded to a negligible extent by dehydrated zeolites (Barrer, *Ann. Reports*, 1944, 41, 44):

Molar ratio of water	10.5	8.36	5.00	2.81	1.18
d_{25}^{25}	2.36, 2.36 *	2.47	2.72	3.02	3.27

* Determined in kerosene.

The density of the final product was equivalent to a contraction in volume of 27.9%.

Yttrium Oxalate.—The solution contained yttrium nitrate 3 g., 66% nitric acid 2 ml., water 100 ml. Duration of precipitation was 2 hours.

Temp.	Molar ratio of water in product.	Remarks.
98°	6.00 *	Short, thick, well-formed crystals
80	7.5—8.5	Mixture
70	9.62, 9.92	Interstitial hydrate, well-formed crystals
25	10.4, 12.9	Mixture of aggregate and poorly-formed crystals
15	16.8, 10.1	Globular aggregates of very small crystals
9	14.8	" " " " "
0	15.5, 16.7, 15.8 †	" " " " "

* Found: Y_2O_3 , 41.1, 41.2; C_2O_4 , 47.9, 48.0. Calc., for $Y_2(C_2O_4)_3 \cdot 6H_2O$; Y_2O_3 , 41.2; C_2O_4 , 47.9%.

† Precipitate digested in mother-liquor for 72 hours.

Precipitates formed at 25° or below appeared to consist either of mixtures of the interstitial hydrate and a higher hydrate such as the 17-hydrate described by Brauner (*loc. cit.*) and by Marsh (*loc. cit.*) or else of a second interstitial hydrate containing approximately 17 or more mols. of water per mol. of oxalate. Physicochemical data are required to reveal the true nature of the solid phase.

Both the interstitial hydrate and the unidentified hydrate obtained below 25° gave the 6-hydrate when heated in water for 7 hours at 98°.

A dihydrate was formed from the hexahydrate at 180° [Found: C_2O_4 , 55.0, 55.0. $Y_2(C_2O_4)_3 \cdot 2H_2O$ requires C_2O_4 , 55.1%. Loss of wt., 13.1. Required for $4H_2O$, 13.1%].

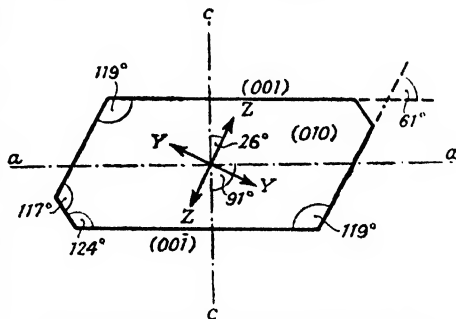

At 180° the interstitial hydrate readily lost approximately 57% of its water content. A further 20% was lost more slowly, leaving a residue in which the molar ratio of water was 2.1—2.2. The unidentified hydrate gave a similar residue at 180°. No further loss of water took place at 220°, and at 280° the oxalate slowly decomposed. Resorption of water vapour at 20° was comparatively rapid when dehydration of the interstitial hydrate was less than 57% complete; beyond this point water vapour was taken up much more slowly, less than 15% of the total water content being resorbed after 45 hours.

"Didymium" Oxalate.—Between 50° and 98° only the interstitial hydrate was precipitated from didymium nitrate solutions comparable in composition to solution (b) used for the preparation of lanthanum oxalate.

Mixed Oxalates.—Solution (a) contained mixed nitrates 10 g., 66% nitric acid 38 ml., water 1 l. Solution (b) contained rare-earth oxides 5.1 g., thoria 0.6 g., sulphuric acid 18.0 g., phosphoric acid 3.2 g., water 100 ml., and was obtained by heating monazite with sulphuric acid, dissolving the sulphates in water and filtering the solution. The interstitial hydrate was the only hydrate obtained from either solution (a) (50—98°) or (b) (80—98°). Crystals precipitated in (a) differed in habit from those precipitated in (b), the former resembling crystals precipitated from lanthanum or cerous nitrate solution. The identity of these products was established by determining the optical properties of the crystals.

Microscopical Examination of Interstitial Hydrate and Reaction Products.—Crystals 40—400 μ in length, surfaces often curved. Inclusions numerous if rapidly precipitated. Flattened perpendicular to *b* axis if deposited by cooling saturated acid solutions.

For lanthanum, cerium, and yttrium hydrates with molar ratios of water 10.3, 10.4, and 9.92, respectively, optical properties were: crystals monoclinic, optically—, $X = b$, $Z \wedge c = 26^\circ \pm 2^\circ$, $2V$ large. Elongation, — in nitrate solution, + in sulphuric-phosphoric acid solution. Refractive indices: α 1.47(5), β 1.55, γ 1.61 [except for the yttrium hydrate: α 1.48(5), β 1.55, γ 1.61]. No changes in α , β , or γ were detected for variations of $\pm 2\%$ in the above values of the molar ratio of water. Cleavage was distinct parallel to (010). The (001) face often showed striae parallel to the 010 edge. "Didymium" and the mixed rare-earth compounds were almost optically identical with the lanthanum and cerium compounds.

Optical orientation of interstitial hydrates.

None of these observations conflicts with a meagre description of a series of 11-hydrates of cerium-group oxalates given by Wyrouboff (*loc. cit.*) with the exception of the angle $Z \wedge c$, which was said to be 18° . The figure gives the optical orientation of the interstitial hydrates, $c \wedge a$ being the axial angle given in Wyrouboff's paper for the lanthanum compound.

Transparent crystals preserving the outline of the parent substance were obtained when 90% of the water of hydration was removed (180°) from lanthanum or cerous oxalate. Although no change was detected in profile views of the (010) face (see fig.), yet profile views of the (001) face disclosed marked changes in inter-edge angles. Cleavage of a number of crystals along the 010 plane was noted. The dehydrated crystals were weakly birefringent and the average refractive index was 1.68—1.69. When treated with water at 20° , these crystals were gradually changed into a mass of small (2—10 μ) acicular crystals, the optical properties of which, as far as could be determined, resembled those of the fully hydrated interstitial hydrate. The recrystallisation process was slightly exothermic. The optical properties of the partly (40—70%) dehydrated oxalates were of an intermediate character, smaller or thinner crystals being apparently dehydrated to a greater extent than others in the same sample. The former reacted with water only if the extent of dehydration approached 90%.

Transparent crystals resembling the parent substance were obtained at 180° only from thin crystals of yttrium oxalate, thicker specimens disintegrating on heating. After loss of 75% of the total water content, a brittle residue was obtained with approximate refractive indices: α 1.50, β 1.67, γ 1.67—1.68. Treatment with water changed this residue into small rectangular laths of the interstitial hydrate.

After ignition for 1 hour at 900° , the interstitial hydrates formed coherent particles of oxides closely resembling the parent crystals, providing these were thin. The particles were highly refractive and the majority showed aggregate polarisation. Prolonged ignition completely destroyed the outline of the original crystals and resulted in formation of opaque, sintered products.

By boiling with 15% aqueous sodium hydroxide the interstitial hydrates were converted into "hydroxides" consisting of discrete particles similar in shape to the parent substance. The particles were isotropic or faintly birefringent. By observing the process on a microscope slide the rate of attack was seen to be rapid even at 20° . The sodium oxalate produced separated from solution in radiating clusters of acicular crystals.

Microscopical Examination of Hexahydrate of Yttrium Oxalate.—Crystals monoclinic, 20—60 μ in length, often pinacoidal parallel to c axis and flattened parallel to (100). Cleavage distinct parallel to (010). Optically—, $X = b$, $Z \wedge c = 40^\circ$, $2V$ small, α 1.47, β 1.61, γ 1.62. A granular mass of small birefringent fragments was formed on heating to 180° . The crystals swelled and disintegrated when treated with 15% sodium hydroxide.

Crystals of the hexahydrate of lanthanum oxalate were too small for satisfactory optical examination.

The author wishes to acknowledge the assistance of Dr. A. R. Alderman and Mr. A. J. Gaskin with the optical determinations.

[Received, February 6th, 1947.]

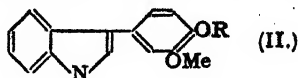

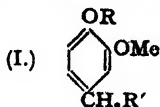

339. Homovanillin.

By A. A. L. CHALLIS and G. R. CLEMO.

Homovanillin (I; $R = H$, $R' = CHO$) was prepared in 65% yield by ozonolysis of *O*-carbethoxyeugenol, followed by catalytic decomposition of the ozonide, and removal of the hydroxyl-protecting group by mild hydrolysis. Eugenol methyl ether and acetyl- and carbobenzyloxy-eugenol similarly gave the analogously substituted homovanillins.

Homovanillin and its derivatives were used in the Fischer indole synthesis, and the Strecker amino-acid synthesis; and condensation with cyclohexanone followed by cyclisation and dehydrogenation provided a new route to substituted phenanthrenes.

HOMOVANILLIN was obtained in poor yield by Harries and Haarmann (*Ber.*, 1915, 48, 29, 868) by ozonolysis of eugenol and decomposition of the ozonide by zinc and acetic acid. We have found that at 0° and in ordinary freezing mixtures a solution of *O*-carbethoxyeugenol (I; $R = CO_2Et$, $R' = \cdot CH_2CH_3$) in ethyl acetate with excess of ozone gives chiefly *O*-carbethoxyhomovanillic acid, but at -70° 5% ozone is almost completely utilised if the special vessel illustrated in the figure is employed, and if the ozonide is immediately decomposed by shaking with hydrogen and palladised charcoal (cf. Henne and Perilstein, *J. Amer. Chem. Soc.*, 1943, 65, 2183), good yields of *O*-carbethoxyhomovanillin were produced which could be converted into homovanillin by hydrolysis in dry 2% alcoholic hydrochloric acid. The final product—a viscous pale yellow oil—did not solidify, but gave a *p*-nitrophenylhydrazone, a 2:4-dinitrophenylhydrazone, and a semicarbazone, all in 85—90% yield. In the presence of even small amounts of aqueous alkali or acid, the homovanillin polymerised, but otherwise was quite stable.

O-Acetylhomovanillin was prepared in an analogous manner. Oxidation in very dilute potassium permanganate solution containing excess of magnesium sulphate gave *O*-acetylhomovanillic acid; more vigorous conditions gave *O*-acetylvanillic acid. Nitration of *O*-acetylhomovanillin in acetic anhydride with the theoretical quantity of nitric acid for either the mono- or the dinitro-compound gave nitrogenous red oils which would not solidify and could not be distilled.

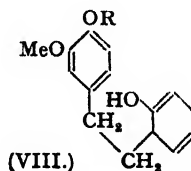

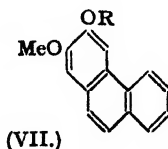

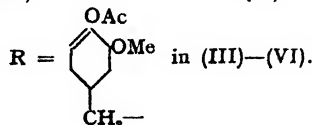

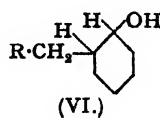

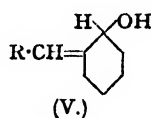

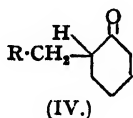

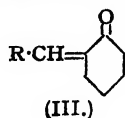

It was found that the ozonide of *O*-carbobenzyloxyeugenol (I; $R = CO_2CH_2Ph$, $R' = CH_2CH_3$) (Bergmann and Zervas, *Ber.*, 1932, 65, 1194; Olcott, *J. Amer. Chem. Soc.*, 1939, 59, 392) gave only *O*-carbobenzyloxyhomovanillin (I; $R = CO_2CH_2Ph$, $R' = CHO$) on catalytic reduction. The use of large amounts of catalyst did not result in hydrogenolysis to homovanillin.

Homovanillin phenylhydrazone was used in a Fischer indole synthesis giving 3-4'-hydroxy-3'-methoxyphenylindole (II; $R = H$). This gave only a slight colour in the Ehrlich rosindole reaction (indoles substituted in position 3 usually give this reaction, and the failure in this case may be due to steric hindrance of the substituent, since neither 2- nor 3-phenylindole gives a colour), but the pine-shaving test was strong, ferric chloride gave a deep red colour, and concentrated sulphuric acid a series of colour changes.

The hydroxyl group of the indole was readily acetylated and benzoylated. These derivatives gave only slight colours in the rosindole test. With the pine-shaving a good violet colour was obtained, but no colour was given with ferric chloride.

O-Acetylhomovanillin was used in a Strecker synthesis of β -4-hydroxy-3-methoxyphenylalanine [I; $R = H$, $R' = CH(NH_2)CO_2H$]. A slight modification of the general method of Cocker and Lapworth (*J.*, 1931, 1391) was used, but the yield obtained (ca. 30%) does not compare with the 65% by the synthesis of Johnson and Bengis (*J. Amer. Chem. Soc.*, 1913, 35, 1613), who hydrolysed vanillylhydantoin, obtained by the reduction of vanillylidenehydantoin, with barium hydroxide.

O-Acetylhomovanillin was condensed with cyclohexanone in technical pyridine to give the homovanillylidene derivative (III), which crystallised only with difficulty, possibly owing to the presence of geometrical isomers; the dihydro-compound (IV) crystallised fairly readily. This was obtained by reduction of (III) either with sodium amalgam in alcohol-acetic acid, or by catalytic hydrogenation, using Adams's catalyst; it was saturated but still gave an oxime. On prolonged refluxing of a moist ethereal solution of (III) with aluminium amalgam, a compound was obtained which was unsaturated and non-ketonic and was consequently formulated as (V). This compound also was difficult to obtain crystalline and when catalytically hydrogenated gave a non-ketonic saturated dihydro-compound identical with that obtained by action of aluminium amalgam on (IV). The latter gives a benzoyl derivative; and is therefore 2-*O*-acetylhomovanillyl-cyclohexanol (VI).

Attempts to cyclise it by using sodium ethoxide, syrupy phosphoric acid, or phosphoric oxide in benzene all failed. This may be due to the fact that while free rotation about the carbon bonds of the atoms joining the two cyclic systems allows favourable orientation of the hydrogen and hydroxyl groups on the two rings, all three bonds would have to be in definite positions to enable this orientation to take place. The substance (III), however, was found to cyclise in small yield in either a boiling benzene suspension of phosphoric oxide or on standing at room temperature in a chloroform solution of phosphorus oxychloride. With these drastic

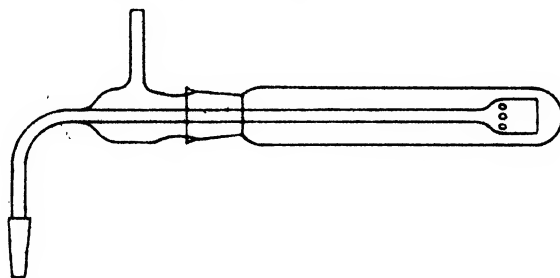

reagents, enolisation and isomerisation of (III) to (VIII) would be expected; this would then cyclise *para* to the methoxy-group and aromatisation would occur to give 3-acetoxy-2-methoxy-9:10-dihydrophenanthrene. This structure was confirmed by a fairly smooth selenium dehydrogenation of the cyclisation product to phenanthrene. Further, less drastic dehydrogenation by heating to 210–220° with palladium-black (Majima and Murahs, *Proc. Imp. Acad. Japan*, 1934, 10, 342) gave 3-acetoxy-2-methoxyphenanthrene (VII, R = Ac; Gilman and Cook, *J. Amer. Chem. Soc.*, 1940, 62, 2816), which was hydrolysed to 3-hydroxy-2-methoxyphenanthrene (VII, R = H; Gilman and Cook, *loc. cit.*); methylation gave 2:3-dimethoxyphenanthrene (VII, R = Me; Pschorr and Buckow, *Ber.*, 1900, 33, 1831).

EXPERIMENTAL.

(All m. p.s and b. p.s are uncorrected. Sodium sulphate was used as the drying agent unless otherwise stated.)

O-Carboethoxyeugenol.—Sodium hydroxide solution (35 g., 40%) was added dropwise with cooling and shaking to a mixture of eugenol (54 g.) and ethyl chloroformate (40 g.). The whole was extracted with ether, the extract washed with water and dried, the ether removed, and the residue distilled in a vacuum (50 g., b. p. 135–138°/1.5 mm.). The distillate solidified to stout rhombs, m. p. 31°.

O-Carboethoxyhomovanillin.—O-Carboethoxyeugenol (10 g.) was dissolved in ethyl acetate (100 c.c.), the solution placed in the ozonolysis vessel (see fig.), and the whole cooled in acetone-Drikold. A

stream of 5% ozone at 50 c.c./min. was passed in for 6 hrs. The cold solution of the ozonide was hydrogenated in the presence of palladised charcoal (2 g.); hydrogen being rapidly absorbed (530 c.c. at 17° and 754 mm. in 40 mins.). The flask was evacuated, air admitted, the flask shaken for 10 mins., the air replaced by hydrogen, and the flask shaken for 5 hrs. The solution was filtered (the catalyst, after being washed with a little alcohol and dried, can be used 10–12 times), and the solvent removed under reduced pressure. The residue was dissolved in ether, the solution washed with saturated sodium hydrogen carbonate solution (washings A, see below), dried, the ether removed, and the residue fractionated in a vacuum: 0.5 g., b. p. 135–140°/2 mm.; 7.5 g., b. p. 150–155°/2 mm.; 1 g., b. p. 170–200°/2–3 mm. The redistilled middle fraction was O-carboethoxyhomovanillin (Found: C, 60.7; H, 6.1. $C_{11}H_{14}O_5$ requires C, 60.5; H, 5.9%); its 2:4-dinitrophenylhydrazones formed short yellow needles, m. p. 129–130° (Found: C, 51.7; H, 4.7. $C_{11}H_{10}O_5N_4$ requires C, 51.7; H, 4.3%), from alcohol, and its *p*-nitrophenylhydrazones crystallised from alcohol in orange-red rhombs, m. p. 85–86° (Found: C, 57.6; H, 5.0. $C_{11}H_{10}O_5N_2$ requires C, 57.8; H, 5.1%).

Homovanillin.—Carboethoxyhomovanillin (4.5 g.) was dissolved in absolute alcohol (75 c.c.), and dry hydrogen chloride (1.5 g.) passed in. The whole was heated for 1 hr. at 60°, the alcohol removed under reduced pressure, and the residue dissolved in ether; the ethereal solution was washed with saturated sodium hydrogen carbonate solution, dried, the ether removed, and the residue twice distilled in a vacuum (3.2 g.), b. p. 147–149°/2 mm. (Found: C, 65.5; H, 6.0. Calc. for $C_9H_{10}O_3$: C, 65.2; H, 6.2%). Homovanillin is a pale oil, stable in air, and giving a blue coloration with ferric chloride. Its 2:4-dinitrophenylhydrazones crystallised from alcohol in yellow cubes, m. p. 203°. Its *p*-nitrophenylhydrazones, recrystallised from ethyl acetate, had m. p. 154° (Harries and Haarmann, *loc. cit.*, give m. p. 154–155°). The semicarbazone, recrystallised from alcohol, had m. p. 173° (Harries and Haarmann, *loc. cit.*, give 173°), and the oxime, colourless needles from alcohol, had m. p. 115° (Harries and Haarmann, *loc. cit.*, give 115°).

O-Carboethoxyhomovanillic Acid.—On acidifying the wash liquor (A) from carboethoxyhomovanillin a colourless crystalline solid was precipitated; it recrystallised from water as glistening, colourless, elongated plates of the acid (0.1 g.), m. p. 125–126° (Found: C, 56.5; H, 5.3. $C_{11}H_{14}O_6$ requires C, 56.7; H, 5.5%).

Homovanillic acid. O-Carboethoxyhomovanillic acid (1 g.) was heated for 2 hours on a water-bath with sodium hydroxide (10%, 6 c.c.), and the product, precipitated by acidification and cooling, was recrystallised from water, forming glistening plates (0.7 g.), m. p. 139° (Harries and Haarmann, *loc. cit.*, give 139°).

O-Acetylhomovanillin.—O-Acetyleneugenol (13 g.) was ozonised for 11 hrs. and worked up in the same manner as the carboethoxy-compound (0.6 g., b. p. 139–135°/2 mm.; 9.2 g., b. p. 140–145°/2 mm.; 2 g., b. p. 150–200°/2 mm.). The redistilled middle fraction (Found: C, 63.1; H, 5.6. Calc. for $C_{11}H_{12}O_4$: C, 63.4; H, 5.8%) gave a 2:4-dinitrophenylhydrazone, which crystallised from alcohol in yellow cubes, m. p. 144–145° (Found: C, 52.8; H, 4.3. $C_{11}H_{10}O_7N_4$ requires C, 52.6; H, 4.1%).

O-Acetylhomovanillic Acid.—(1) Homovanillic acid (0.5 g.) was dissolved in a solution of sodium hydroxide (0.3 g.) and poured into acetyl chloride (1 c.c.). The product which separated on cooling crystallised from water in glistening plates (0.45 g., m. p. 135–136°) (Harries and Haarmann, *loc. cit.*, give 134°). Hydrolysis gave homovanillic acid, m. p. and mixed m. p. 139°.

(2) The bicarbonate wash liquor from acetylhomovanillin gave, on acidification and recrystallisation from water, the same acid (0.2 g., m. p. and mixed m. p. 135–136°).

(3) *O*-Acetyl Eugenol (2 g.) in ethyl acetate (100 c.c.) was ozonised for 12 hrs. at 0°. Removal of the solvent, dissolution of the residue in ether, extraction of the ethereal solution with saturated bicarbonate solution, and acidification of the extract gave acetylhomovanillic acid (1.2 g.), m. p. and mixed m. p. 135–136°.

(4) Acetylhomovanillin (2 g.) in acetone (15 c.c.) was shaken with a solution of potassium permanganate (1 g.) in water (1500 c.c.) containing magnesium sulphate (2 g.) for 24 hrs. The manganese dioxide was filtered off, and the filtrate evaporated to dryness. Hydrochloric acid (6*N*, 13 c.c.) was added, and acetylhomovanillic acid filtered off and recrystallised from water (0.8 g.), m. p. and mixed m. p. 135–136°; a small amount of homovanillic acid was also formed.

Vanillic Acid.—Acetylhomovanillin (1 g.) in acetone (30 c.c.) was shaken with potassium permanganate (1 g.) dissolved in water (100 c.c.), the manganese dioxide filtered off, the filtrate evaporated to dryness, and the residue ground with concentrated hydrochloric acid (5 c.c.) and warmed on the water-bath for 15 mins. The vanillic acid was filtered off, and recrystallised from water as lustreless cubes (0.25 g., m. p. and mixed m. p. 207°).

Nitration of *O*-Acetylhomovanillin.—Fuming nitric acid (*d* 1.52, 0.36 g.) was added dropwise to a mechanically stirred solution of acetylhomovanillin (2 g.) in acetic anhydride (25 c.c.) in a freezing mixture, and the whole was set aside overnight. Urea (1 g.) was added, the mixture diluted with water (100 c.c.) and extracted with ether, the extract washed with sodium hydrogen carbonate solution (5%), dried, and the ether removed. The residue was a deep red oil which solidified in "Drikold" but melted again at room temperature; it could not be distilled. Use of twice the quantity of nitric acid and warming the reaction mixture on the water-bath gave an apparently identical product.

***O*-Carbobenzyloxyeugenol.**—Carbobenzyloxy chloride (3.5 g.) (Bergmann and Zervas, *loc. cit.*) was added to a suspension of eugenol (3 g.) in water (70 c.c.) containing sodium carbonate (1 g.). The whole was shaken for 48 hrs., the smell of the acid chloride then having almost gone (cf. Olcott, *loc. cit.*). The suspension was extracted with ether, the extract dried, the ether removed, and the residue distilled in a vacuum (5.8 g., b. p. 170–180°/1–2 mm.). On standing, the distillate solidified into stout needles, m. p. 53°.

***O*-Carbobenzyloxyhomovanillin.**—Carbobenzyloxyeugenol (13 g.) was ozonised for 6 hrs. and worked up in the same manner as the carbethoxy-compound except that 6 g. of palladised charcoal were used. The middle fraction (9 g., b. p. 160–170°/1 mm. Found: C, 67.7; H, 5.5. $C_{17}H_{16}O_8$ requires C, 68.0; H, 5.3%) gave no coloration with ferric chloride.

***O*-Carbobenzyloxyhomovanillic Acid.**—The bicarbonate wash liquor from the last experiment, on neutralisation, gave this acid, which crystallised from water in long lustrous needles (0.8 g., m. p. 107–108°). On refluxing with hydrochloric acid (4*N*, 10 c.c.), this gave homovanillic acid, m. p. and mixed m. p. 139°.

3-4'-Hydroxy-3'-methoxyphenylindole.—Homovanillin (2.2 g.) and phenylhydrazine (1.5 g., freshly distilled) were refluxed in alcohol (25 c.c.) for 3 hrs., and the alcohol distilled off. Fresh alcohol (25 c.c.) was added and the solution saturated with dry hydrogen chloride and refluxed for 1 hr. The alcohol was distilled off, alcohol (25 c.c.) added, and the whole saturated with dry hydrogen chloride at 0° and set aside overnight, then refluxed for 1 hr. and the alcohol distilled off. The residue was extracted with hot benzene, and the extract cooled, filtered, and the benzene removed. The residual oil (0.5 c.c.), dissolved in benzene (0.7 c.c.), was poured dropwise into well-stirred light petroleum (b. p. 40–60°). The creamy-white precipitate was filtered off and washed with a little light petroleum, then recrystallised from benzene-light petroleum (b. p. 80–100°) (0.5 g., m. p. 117°, softening at 100°) (Found: C, 75.1; H, 5.4. $C_{15}H_{13}O_2N$ requires C, 75.3; H, 5.45%). The indole is soluble in alcohol, benzene, acetone, acetic anhydride, and sodium hydroxide solution, and slightly soluble in hot light petroleum. It gives no coloration in the Ehrlich test, but gives a red-violet pine-shaving reaction, and with concentrated sulphuric acid, a blood-red colour, changing to purple and brown. 3-Phenylindole also gives no Ehrlich test, but with concentrated sulphuric acid it gives a yellow colour, changing to red and brown.

The *O*-acetyl derivative, had m. p. 96° (softening at 90°) (Found: C, 70.9; H, 5.1. $C_{17}H_{15}O_3N$ requires C, 71.4; H, 5.6%), and the *O*-benzoyl derivative m. p. 133° (softening at 130°) (Found: C, 78.2; H, 4.5. $C_{22}H_{17}O_3N$ requires C, 78.9; H, 4.95%), both from benzene light petroleum (b. p. 80–100°).

Both compounds were soluble in organic solvents, but almost insoluble in sodium hydroxide solution or water; neither gave an Ehrlich reaction, but both gave a violet colour in the pine-shaving test.

β-4-Hydroxy-3-methoxyphenylalanine.—*O*-Acetylhomovanillin (20 g.) was dissolved in liquid hydrogen cyanide (40 c.c.), and after 10 mins. the solution was slowly added with stirring to a solution of ammonia (20 g.) in water (25 c.c.) cooled to –70°. The result was sealed, and the mixture set aside overnight and then slowly added to a mechanically stirred solution of sulphuric acid (1200 c.c., 40%), heated to 125° for 3 hrs., and poured into water (2 l.). The solution was heated to boiling and barium hydroxide (700 g.) added. Superheated steam was passed through the boiling solution, while barium carbonate was added in small portions till no more ammonia was evolved (ca. 250 g. required). Dilute sulphuric acid was added until the solution showed the presence of sulphate ion, and the barium sulphate was filtered off and well washed, and the combined filtrate and washings concentrated to 100 c.c. The hot solution was treated with lead carbonate until effervescence ceased (ca. 10–12 g.); it was not acid to Congo-red. The whole, after standing overnight, was filtered and the filtrate saturated with hydrogen sulphide, allowed to stand, and refiltered. After being boiled with charcoal (3 g.), the filtered solution was concentrated to 20 c.c. and set aside. The crystals (5 g., and a further 1.4 g. obtained on concentration) melted at 228–229°. Recrystallisation from water afforded colourless needles (4 g.), m. p. 254–255° (decomp.), after losing water of crystallisation (Johnson and Bengis, *loc. cit.*, report a dihydrate, m. p. 255–256°, decomp.).

The anhydrous hydrogen cyanide used was conveniently stored in an equal volume of glacial acetic acid. No heat was evolved on mixing, and the solution was kept in an ordinary well-stoppered bottle without deterioration. The pure cyanide was obtained by distilling the solution from a bath at 30–40°.

2-O-Acetylhomovanillylidene-cyclohexanone (III).—Acetylhomovanillin (13 g.) and cyclohexanone (8 g.) in dry technical pyridine (80 c.c., b. p. 135°) were heated under reflux for 8 hrs., the solvent evaporated off, and the residue poured into water (180 c.c.). The mixture was acidified and extracted with warm benzene, the extract washed (dilute hydrochloric acid; dilute sodium hydroxide solution; water), dried, and refluxed for 0.5 hr. with active charcoal (2 g.). The hot solution was filtered and concentrated to 40 c.c., the residue poured dropwise into well-stirred cold light petroleum (b. p. 40–60°), and the creamy-white precipitate of the compound (III) (18 g.) filtered off, washed with a little petroleum, and recrystallised from benzene–light petroleum or dilute alcohol (10 g.), m. p. 84° (Found: C, 70.5; H, 7.3. $C_{17}H_{20}O_2$ requires C, 71.0; H, 7.0%). The oxime formed needles, m. p. 106°, from alcohol.

2-Homovanillylidene-cyclohexanone.—(1) The above ketone (0.5 g.) was shaken with sodium hydroxide solution (6%, 25 c.c.) at 100° for 0.5 hr., then heated at this temperature for 1 hr. After cooling, the solution was extracted with ether, acidified, and extracted with benzene. The benzene extract was dried and boiled under reflux with active charcoal (0.2 g.) for 0.25 hr. The extract was filtered, concentrated to 4 c.c., and poured dropwise with stirring into cold light petroleum (b. p. 40–60°). The creamy-white precipitate was filtered off and washed with a little petroleum, then recrystallised from benzene–light petroleum or dilute alcohol (0.3 g., m. p. 105°).

(2) **O-Acetylhomovanillin** (3.5 g.) and cyclohexanone (2 g.) were refluxed in absolute alcohol (50 c.c.) containing sodium (2.5 g.) for 4 hrs. Glacial acetic acid (6.5 c.c.) was added, and the alcohol removed. The residue was poured dropwise into well-stirred ice-water, and the precipitate collected, washed, dried, dissolved in benzene (50 c.c.), and worked up as above, giving 3 g., m. p. and mixed m. p. with the above 105°.

2-O-Acetylhomovanillyl-cyclohexanone (IV).—(1) 2-Acetylhomovanillylidene-cyclohexanone (3 g.) was dissolved in alcohol (25 c.c.), and the solution vigorously stirred while sodium amalgam (4%, 40 g.) was added in small portions. The solution was kept just acid by gradual addition of glacial acetic acid (4.5 c.c.). The temperature towards the end of the reaction was kept between 50° and 60°. The whole was made slightly basic (sodium hydroxide) and evaporated to dryness. The residue was extracted with hot benzene, the extract washed with a little water, dried, refluxed with active charcoal (0.8 g.) for 0.3 hr., filtered, concentrated to 8 c.c., and poured dropwise into well-stirred cold light petroleum (b. p. 40–60°). The colourless precipitate was collected, washed with a little petroleum, and crystallised from benzene–light petroleum or dilute alcohol (2.5 g., m. p. 134°).

(2) The same ketone (30.13 mg.) was quantitatively hydrogenated in glacial acetic acid (10 c.c.) with freshly reduced Adams's catalyst (3 mg.), 2.30 c.c. of hydrogen at N.T.P. being absorbed in 20 mins. (0.985 double bond). The solution was filtered and concentrated to 1.5 c.c., water (20 c.c.) was added, and the precipitate recrystallised from benzene–light petroleum, giving 0.02 g., m. p. and mixed m. p. with the above 134°. The compound was saturated and gave an oxime, needles (from alcohol), m. p. 83°.

2-O-Acetylhomovanillylidenecyclohexanol (V).—2-Acetylhomovanillylidene-cyclohexanone (3 g.), dissolved in moist ether (150 c.c.), was heated under reflux for 12 hrs. with freshly prepared aluminium amalgam (4 g.), the mixture filtered, and the alumina and excess of amalgam washed with ether; the filtrate and washings were dried, the ether removed, and the residual oil dissolved in benzene (8 c.c.) and poured dropwise into well-stirred cold light petroleum. The precipitate was collected, washed with a little petroleum, and recrystallised from benzene–light petroleum. The compound (2.4 g., m. p. 151°) was unsaturated and did not form an oxime, but was soluble in sodium hydroxide.

2-O-Acetylhomovanillyl-cyclohexanol (VI).—(1) The above hexanol (36.41 mg.) was quantitatively hydrogenated in glacial acetic acid solution (10 c.c.) with freshly reduced Adams's catalyst (5 mg.); 2.76 c.c. of hydrogen at N.T.P. were absorbed in 15 mins. (0.982 double bond). The solution was filtered and concentrated to 1.3 c.c., water (20 c.c.) was added, and the precipitate recrystallised from benzene–light petroleum (0.02 g., m. p. 171°).

(2) 2-Acetylhomovanillyl-cyclohexanone (3 g.), treated with aluminium amalgam and worked up exactly as in the preparation of (V), gave 2.58 g., m. p. and mixed m. p. with preparation (1) 171°; the compound (VI) was saturated and non-ketonic (Found: C, 70.0; H, 8.0. $C_{17}H_{24}O_2$ requires C, 70.0; H, 8.2%). This gave a benzoate, m. p. 156° (Found: C, 72.4; H, 6.9. $C_{21}H_{28}O_3$ requires C, 72.7; H, 7.1%), from benzene–light petroleum.

Attempted Cyclisations.—(1) **2-Homovanillyl-cyclohexanol.** 2-Acetylhomovanillyl-cyclohexanol (0.3 g.), dissolved in absolute alcohol (10 c.c.) containing sodium (0.2 g.), was heated under reflux for 2 hrs. Glacial acetic acid (1 c.c.) was then added, and the whole evaporated to dryness. The residue was extracted with ether, and the extract washed (sodium carbonate), and dried. The ether was removed, and the oily residue dissolved in benzene (1.5 c.c.) and poured into cold, well-stirred light petroleum (b. p. 40–60°). The precipitate, recrystallised from benzene–light petroleum (0.14 g.), had m. p. 161–163° and was probably 2-homovanillyl-cyclohexanol (Found: C, 72.1; H, 8.5. $C_{17}H_{22}O_2$ requires C, 72.0; H, 8.8%).

(2) The cyclohexanol (0.5 g.) was stirred into syrupy phosphoric acid (3 c.c.) and set aside for 10 hrs. The whole was poured into water, basified (sodium hydroxide), and extracted with ether. This extract contained only a trace of material. The aqueous solution was acidified and extracted with ether, and the extract worked up like the ethereal extract in (1), giving 0.3 g., m. p. and mixed m. p. with the starting material 171°.

(3) The cyclohexanol (0.5 g.) was stirred into syrupy phosphoric acid (3 c.c.) and warmed on the water-bath for 1 hr. Considerable tar was formed. Working up as in (2) afforded only 0.1 g. of starting material.

(4) To the cyclohexanol (0.3 g.) refluxing in benzene (10 c.c.), phosphoric oxide (0.6 g.) was added in small portions during 1.5 hrs. Water (25 c.c.) was added to the cooled reaction mixture, and the whole worked up as above. Only impure starting material (0.1 g.) was obtained.

3-Acetoxy-2-methoxy-9:10-dihydrophenanthrene. (1) 2-O-Acetylhomovanillylidene-cyclohexanone (10

g.) and benzene (100 c.c.) were heated under reflux while phosphoric oxide (10 g.) was added in small portions during 3 hrs. The mixture was decomposed with water (200 c.c.), and the whole basified (sodium hydroxide) and extracted with ether (extract *A*). The aqueous solution was acidified and extracted again with ether (extract *B*). Extract *A* was washed with water, dried, and the ether removed. The residue, recrystallised several times from dilute alcohol, gave needles (0.18 g.), m. p. 174° (Found: C, 75.9; H, 5.66. $C_{11}H_{14}O_2$ requires C, 76.1; H, 6.0%). Extract *B* similarly gave 0.049 g. of leaflets from dilute alcohol, m. p. 147° (compound *H*).

(2) The cyclohexanone (5 g.) was dissolved in chloroform (40 c.c.), and phosphorus oxychloride (6 c.c.) added. The whole was kept overnight, shaken with water, and then with sodium carbonate solution. The chloroform layer was filtered and dried, the chloroform removed, and the residue (ca. 1 g.) dissolved in a little alcohol. The crystals deposited on standing were recrystallised from dilute alcohol, affording needles (0.2 g.), m. p. and mixed m. p. with the above 174°.

The above compound, m. p. 174° (0.05 g.), was heated at 290–300° with selenium (0.1 g.). The sublimate (ca. 0.03 g.), resublimed in a vacuum, had m. p. and mixed m. p. with phenanthrene, 99°; picrate (from alcohol), m. p. 141°.

3-Acetoxy-2-methoxyphenanthrene (VII; R = Ac).—(1) The above dihydro-compound (0.1 g.) was mixed with palladium-black (0.1 g.) and heated at 210–220° until no further change was visible. Alcohol (2 c.c.), was added, the whole warmed and filtered, the filtrate concentrated to 0.3 c.c., and hot water (1 c.c.) added. The crystals which separated on cooling, recrystallised from dilute alcohol, formed needles (0.02 g.), m. p. 144°.

(2) The dihydro-compound (0.3 g.) was heated under reflux for 5 hrs. with maleic acid (0.8 g.), palladium-black (0.25 g.), and water (6 c.c.), diluted with alcohol (12 c.c.), filtered hot, and the filtrate evaporated to dryness. The residue was warmed and stirred with sodium carbonate solution (12 c.c.) and extracted several times with ether, the extract dried, and the ether removed. The residue recrystallised from alcohol in stout, colourless needles (0.2 g.), m. p. 144° (Gilman and Cook, *loc. cit.*, give 146–147°) (Found: C, 74.6; H, 5.6. Calc. for $C_{17}H_{14}O_2$: C, 74.9; H, 5.3%).

3-Hydroxy-2-methoxyphenanthrene. (1) The above acetoxy-compound (0.16 g.) was heated for 2 hrs. with sodium hydroxide solution (8%, 3 c.c.), and the solution acidified, allowed to cool, and filtered. The precipitate recrystallised from dilute alcohol in short needles (0.11 g.), m. p. 143° (Gilman and Cook, *loc. cit.*, give 145–146°) (Found: C, 80.3; H, 5.6. Calc. for $C_{17}H_{14}O_2$: C, 80.5; H, 5.35%).

(2) Compound *H* (above) (0.03 g.) was refluxed for 4 hrs. with maleic acid (0.1 g.), palladium-black (0.05 g.), and water (1.2 c.c.), and the product worked up as above; it gave 0.01 g. of needles, m. p. and mixed m. p. with the above, 143°.

2:3-Dimethoxyphenanthrene. The above hydroxy-compound (0.1 g.) was dissolved in sodium hydroxide solution (3 c.c., 2%), and the solution heated on the water-bath. Methyl sulphate (0.1 c.c.) was added with stirring, and after 0.25 hr., sodium hydroxide solution (3 c.c., 4%) was added, and the whole heated for a further 0.25 hr. The reaction mixture when cold was extracted with ether, and the extract dried. The ether was removed, and the residue recrystallised from dilute alcohol in leaflets (0.08 g.), m. p. 130–131° (Pschorr and Buckow, *loc. cit.*, and Pschorr, *Annalen*, 1912, 391, 39, give m. p. 131°) (Found: C, 80.5; H, 5.7. Calc. for $C_{18}H_{14}O_2$: C, 80.7; H, 5.9%). The picrate separated in yellow needles, m. p. 125–126° (Pschorr, *loc. cit.*, gives 127°).

NOTES.

Derivatives of Indene and of Butyric Acid. By J. S. H. DAVIES and D. S. MORRIS.

THE work of various authors (*Chem. Reviews*, 1945, 37, 481) has shown that certain derivatives of 6-hydroxy-2-*p*-hydroxyphenylindene and of 6-hydroxy-2-*p*-hydroxyphenyl-3:4-dihydronaphthalene possess oestrogenic activity. Our programme to extend the work of these authors, although well advanced, was anticipated by the publication of Silverman and Bogert (*J. Org. Chem.*, 1946, 11, 34).

The present note deals with two similar indenenes, not previously described, and also with unsuccessful attempts to prepare α -diphenylbutyric acid and α -di-*p*-methoxyphenylbutyric acid from ethyl α -diphenylacetoacetate and its di-*p*-methoxy-derivative respectively, as intermediates in an alternative route to 2-phenyltetralone and 7-methoxy-2-*p*-methoxyphenyltetralone.

6-Methoxy-2-*p*-methoxyphenylindene.—The 6-methoxy-2-*p*-methoxyphenylindanone required was prepared by the route independently used by Silverman and Bogert (*loc. cit.*). The indanone (1 g.) was hydrogenated at ordinary temperature and pressure in ethyl alcohol in presence of Raney nickel (2 g.). The residue obtained after filtration and removal of solvent was stirred with concentrated sulphuric acid (1 drop), warmed for a few minutes on the water-bath, and extracted with benzene. The indene formed small needles, m. p. 194° from alcohol (Found: C, 80.2; H, 6.2. $C_{17}H_{14}O_2$ requires C, 81.0; H, 6.3%).

6-Methoxy-2:3-di-*p*-methoxyphenylindene.—The above indanone (1.5 g.) in toluene (14 c.c.) was added to the Grignard reagent prepared from *p*-anisyl bromide (2.1 g.), magnesium (0.27 g.), and ether (28 c.c.). After the ether had been removed, the toluene solution boiled for 1 hour, and the complex decomposed, the residue from the toluene was dissolved in a mixture of light petroleum (b. p. 40–60°) and benzene (1:1 by vol.) and chromatographed (alumina). Pure 6-methoxy-2:3-di-*p*-methoxyphenylindene (0.7 g.) was obtained as small needles, m. p. 129–130° (Found: C, 80.0; H, 6.4. $C_{24}H_{20}O_2$ requires C, 80.4; H, 6.1%).

β -Hydroxy- α -diphenylbutyric Acid.—Ethyl α -diphenylacetoacetate (28.2 g.), prepared by the

method of Conant and Blatt (*J. Amer. Chem. Soc.*, 1929, **51**, 1227), was hydrogenated in ethyl alcohol at atmospheric pressure and a maximum temperature of 50–60° in presence of Raney nickel; only one molecular proportion of hydrogen was absorbed. Removal of the catalyst and solvent, followed by hydrolysis of the residue by refluxing it for 4 hours with potassium hydroxide (6.5 g.) in 50% aqueous alcohol, furnished a mixture of a neutral substance (3.8 g.), believed to be phenylethyl alcohol, and β -hydroxy- α -diphenylbutyric acid (13.5 g.) which formed needles, m. p. 210°, from aqueous methyl alcohol (Found: C, 75.1; H, 6.6; equiv., 254. $C_{18}H_{18}O_2$ requires C, 75.0; H, 6.3%; equiv., 256).

The application of Rosenmund's procedure (*Ber.*, 1942, **75**, 1850) to ethyl α -diphenylacetoacetate (1 g.) using palladised barium sulphate (1 g.) in acetic acid (100 c.c.) containing perchloric acid (1 drop) in order to effect further reduction was unsuccessful, the products isolated after hydrolysis being β -hydroxy- α -diphenylbutyric acid (0.3 g.), phenylacetic acid (0.7 g.), and a neutral substance, probably phenylethyl alcohol. The hydrogenation of sodium β -hydroxy- α -diphenylbutyrate in water with copper chromite at 200° and 160 atmospheres gave likewise an acidic product consisting almost entirely of phenylacetic acid.

Ethyl ester. The β -hydroxy-acid (10.5 g.) was refluxed for 4 hours in ethyl alcohol saturated with dry hydrogen chloride. The ester was obtained as an oil (9.5 g.), b. p. 158–160°/1 mm., which slowly solidified and melted at 61–62° (Found: C, 76.3; H, 7.3. $C_{18}H_{20}O_2$ requires C, 76.1; H, 7.0%).

All attempts to dehydrate the acid or ester, which included the phosphoric oxide method of Kon and Nargund (*J.*, 1932, 2461) and the xanthate method (Kon and Narracott, *J.*, 1938, 672), were unsuccessful.

Ethyl α -Di-*p*-methoxyphenylacetoacetate.—Following the method of Conant and Blatt (*loc. cit.*), ethyl *p*-methoxyphenylacetate (114 g.) in ether (100 c.c.) was slowly added to a stirred, cold solution of isopropylmagnesium bromide, prepared from isopropyl bromide (123 g.), magnesium (24.3 g.), and ether (200 c.c.). The mixture was stirred at room temperature for 1 hour, refluxed for 4 hours, and left overnight. Propane was evolved during the reaction. After processing, the oil was distilled and the fraction, b. p. 140–150°/0.0001 mm. (56 g.), was collected. This fraction solidified on standing and was crystallised from alcohol to yield the ester as pale yellow needles, m. p. 61–62° (Found: C, 70.4; H, 6.4. $C_{20}H_{22}O_4$ requires C, 70.2; H, 6.4%).

β -Hydroxy- α -di-*p*-methoxyphenylbutyric Acid.—The above ester (4.5 g.) in ethyl alcohol (200 c.c.) was hydrogenated at ordinary temperature and pressure in the presence of Raney nickel (2 g.); only one molecular proportion of hydrogen was absorbed. Removal of the catalyst and solvent gave the crude ester as an oil (4.5 g.). The oil (1 g.) was shaken for 6 hours at room temperature with aqueous sodium hydroxide (20 c.c., 2N) and ethyl alcohol (10 c.c.). The acid (0.4 g.) was obtained as small needles, m. p. 135–136° raised to 138° after crystallisation from benzene-light petroleum (b. p. 40–60°) (Found: C, 68.3; H, 6.6. $C_{18}H_{20}O_5$ requires C, 68.4; H, 6.3%).—BRITISH SCHERING RESEARCH INSTITUTE, BROOK LANE, ALDERLEY EDGE, CHESHIRE. [Received, January 21st, 1947.]

Compounds Related to 2:3-Dimethylpyridine. By AHMED MUSTAFA and MUSTAFA KAMAL HILMY.

(I) **Action of Aromatic Aldehydes on 2:3-Dimethylpyridine.**—(a) *In presence of acetic anhydride.* The following stilbazoles were prepared by refluxing the appropriate benzaldehyde (1 mol.) with 2:3-dimethylpyridine (1 mol.) and acetic anhydride (6 mols.) for 30 hours, followed by steam distillation (cf. Shaw and Wagstaff, *J.*, 1933, 77). **3-Methyl-2-stilbazole**, obtained as colourless crystals from light petroleum (b. p. 30–50°), m. p. 55° (Found: C, 85.8; H, 6.5; N, 7.1. $C_{14}H_{13}N$ requires C, 86.2; H, 6.6; N, 7.2%), was easily soluble in benzene, alcohol, and hot light petroleum (b. p. 50–70°); picrate, yellow needles, m. p. 198° from alcohol. Its 2'-nitro-derivative, pale yellow needles from light petroleum (b. p. 50–80°), m. p. 105° (Found: C, 69.9; H, 5.0; N, 11.7. $C_{14}H_{11}O_2N_2$ requires C, 70.0; H, 5.0; N, 11.7%), was easily soluble in ether and hot ethyl alcohol; picrate, yellow crystals, m. p. 190–191° from alcohol. Its 3'-nitro-derivative, yellow crystals from ethyl alcohol, m. p. 124° (Found: C, 69.7; H, 5.0; N, 11.7%), was difficultly soluble in cold benzene or cold ethyl alcohol; picrate, yellow crystals, m. p. 208–209° from alcohol; and the 4'-nitro-derivative, yellow crystals from alcohol, m. p. 145° (Found: C, 69.7; H, 4.9; N, 11.8%), was soluble in hot ethyl alcohol and hot benzene; picrate, yellow crystals, m. p. 198–199°, from alcohol.

(b) *In presence of water.* The following alkenes were prepared by heating the aromatic aldehyde and 2:3-dimethylpyridine (1 mol. each) with water (4 mols.) in a sealed tube for 10 hours at 170°. The mixtures were not homogeneous at room temperature. The products were treated as in the preparation of the corresponding stilbazoles (Shaw and Wagstaff, *loc. cit.*). They crystallised as pale yellow crystals from ethyl alcohol. **2'-Nitro-3-methyl-2-stilbazolealkene**, m. p. 105° (Found: C, 65.1; H, 5.1; N, 10.5. $C_{14}H_{11}O_2N_2$ requires C, 65.1; H, 5.4; N, 10.9%); **3'-nitro-analogue**, m. p. 131° (Found: C, 65.0; H, 5.3; N, 11.1%); **4'-nitro-isomer**, m. p. 125–126° (Found: C, 65.1; H, 5.4; N, 10.6%).

The above three alkenes (1 mol. each), boiled with acetic anhydride (4 mols.) for 2 hours, afforded the corresponding stilbazoles (mixed m. p.) in almost pure condition.

(II) **Action of Aromatic Aldehydes on 2:3-Dimethylpyridine Methiodide.**—Solutions of equimolecular amounts of the reagents in a minimum of absolute ethyl alcohol, treated with a few drops of piperidine and then set aside at room temperature for some time, deposited crystals of the condensation product; when this was heated at about 260° under reduced pressure, the corresponding stilbazole distilled over (cf. Koelsch, *J. Amer. Chem. Soc.*, 1944, **66**, 2166).

2:3-Dimethylpyridine methiodide, colourless crystals from absolute ethyl alcohol, m. p. 205° (Found: C, 39.0; H, 5.0; N, 5.6; I, 51.1. $C_8H_{10}NI$ requires C, 38.5; H, 4.8; N, 5.6; I, 51.0%), easily soluble in cold water and soluble in ether, afforded **4'-methoxy-2-methyl-2-stilbazole methiodide**, yellow needles from water, m. p. 234° (decomp.; orange melt) (Found: C, 52.4; H, 4.9; N, 3.7; I, 34.2. $C_{14}H_{15}ONI$ requires C, 52.3; H, 4.9; N, 3.8; I, 34.6%), readily soluble in hot water and practically insoluble in benzene and light petroleum (b. p. 30–50°). The corresponding stilbazole formed almost colourless crystals from light petroleum (b. p. 50–70°), m. p. 88° (Found: C, 79.7; H, 6.7; N, 6.2. $C_{14}H_{15}ON$

requires C, 80.0; H, 6.6; N, 6.2%); it was soluble in ethyl alcohol; picrate, yellow crystals, m. p. 196–197° from ethyl alcohol.

2'-Methoxy-3-methyl-2-stilbazole methiodide formed yellow crystals from water, m. p. 205° (decomp.) (Found: C, 52.3; H, 4.8; N, 3.7; I, 35.0%), and the stilbazole separated in colourless crystals from light petroleum (b. p. 30–50°), m. p. 60° (Found: C, 79.6; H, 6.5; N, 5.9%); picrate, yellow crystals from alcohol, m. p. 208–209°.

3'-Nitro-3-methyl-2-stilbazole methiodide, pale yellow crystals from water, m. p. 245° (decomp.) (Found: C, 44.9; H, 4.4; N, 6.7; I, 32.1. $C_{18}H_{15}O_2N_2I \cdot H_2O$ requires C, 45.0; H, 4.3; N, 7.0; I, 31.7%), difficultly soluble in cold ethyl alcohol and light petroleum (b. p. 30–50°), afforded the stilbazole as yellow crystals from light petroleum (b. p. 90–100°), m. p. 124° (Found: C, 69.5; H, 5.2; N, 11.6%), identical (mixed m. p.) with the specimen described in (I).

3-Methylpiperolidine-2-picoline methiodide, yellow crystals from hot water, m. p. 260° (Found: C, 50.4; H, 4.5; N, 3.7; I, 33.0. $C_{18}H_{15}O_2NI$ requires C, 50.4; H, 4.2; N, 3.7; I, 33.3%), almost insoluble in light petroleum (b. p. 50–70°), afforded the base as almost colourless crystals from light petroleum (b. p. 90–100°), m. p. 117° (Found: C, 75.0; H, 5.4; N, 6.1. $C_{15}H_{13}O_2N$ requires C, 75.3; H, 5.4; N, 5.9%), soluble in hot ethyl alcohol or benzene; picrate, yellow crystals, m. p. 219° (decomp.), from ethyl alcohol.

4'-Dimethylamino-3-methyl-2-stilbazole methiodide, reddish silky crystals from hot water, m. p. 255° (decomp.) (Found: N, 6.9; I, 33.0. $C_{18}H_{19}N_2I$ requires N, 7.4; I, 33.4%), almost insoluble in cold water and in light petroleum (b. p. 30–50°), afforded the stilbazole as golden-yellow needles from ethyl alcohol, m. p. 93° (yellow-brown melt) (Found: C, 80.5; H, 7.5. $C_{18}H_{19}N_2$ requires C, 80.7; H, 7.5%), soluble in benzene and hot light petroleum (b. p. 80–90°); picrate, brick red crystals, m. p. 202° (red melt) from ethyl alcohol.

(III) Action of Alcoholic Potassium Hydroxide on Stilbazoles.—4'-Nitro-3-methyl-2-stilbazole (1 g.) and ethyl alcoholic potassium hydroxide (15%; 10 c.c.) were heated at 100° for 15 minutes; the crystals which separated were filtered off, washed with water, and crystallised from benzene, forming golden-yellow crystals, m. p. 220° (red melt) (Found: C, 78.2; H, 5.6; N, 13.3. $C_{22}H_{14}ON_4$ requires C, 77.8; H, 5.5; N, 13.0%). 4'-Azoxy-3-methyl-2-stilbazole was difficultly soluble in ethyl alcohol and gave a deep red colour with concentrated sulphuric acid. Similarly, the 3'-azoxy-compound was obtained as brown crystals from benzene, m. p. 157° (Found: C, 78.2; H, 5.3; N, 12.9%), difficultly soluble in cold ethyl alcohol and giving a red colour with sulphuric acid; and the 2'-azoxy-isomer formed pale yellow crystals, from benzene, m. p. 174° (Found: C, 78.3; H, 5.6; N, 12.7%), difficultly soluble in ethyl alcohol and giving an orange-red colour with sulphuric acid.—FOUAD I UNIVERSITY, FACULTY OF SCIENCE, ABBASSIA-CAIRO, EGYPT. [Received, January 27th, 1947.]

The Infra-red Spectrum of Vulcanised Rubber and the Chemical Reaction Between Rubber and Sulphur.

By N. SHEPPARD and G. B. B. M. SUTHERLAND.

IN an earlier paper (*Trans. Faraday Soc.*, 1945, **41**, 261) we described an infra-red spectroscopic investigation of the vulcanisation of rubber, and drew attention to a band at 10.4μ (960 cm^{-1}) which appeared in the spectrum of both straight and accelerated vulcanisation. We have further investigated this phenomenon and find that the intensity of this band correlates well with the amount of sulphur chemically incorporated, but not with the degree of vulcanisation as reflected in the physical properties of the finished product.

We were unable to explain this band in a convincing manner in terms of C-S linkages, but more recently have found a band in the same position (10.4μ), and another at 11.2μ (890 cm^{-1}) in certain thermally degraded rubbers. Since in this case the two new bands are obviously due respectively to the development of new CHR:CHR', and CRR':CH₂ groups, it seemed probable that the 10.4μ band in vulcanised rubber might also be caused by new groupings of the former type. An investigation of the spectrum of an ebonite (in which the rubber-sulphur reaction has been carried to an extreme) gave confirmation of this idea. In this spectrum, absorptions in the region of 6μ showed that a considerable number of double bonds remained, but the characteristic absorption at 12.0μ arising from CRR':CHR' groups in rubber had largely disappeared. On the other hand the band at 10.4μ (although now shifted to slightly longer wave-lengths) had greatly increased in intensity.

These facts find a convincing explanation in the hypothesis that the reaction between rubber and sulphur causes at some stage a shift in the position of the double bond of type —CMe:CH— in the rubber chain, giving rise to a group of the type CHR:CHR. Further confirmation of this comes from the studies of Farmer and Shipley (this vol. p. 1519) on the reaction between sulphur and the diolefins, geraniolene and dihydromyrcene. The available data on the structures of these reaction products have led these authors to conclude that α -methylene initiation of the sulphuration reaction occurs to an important extent.

They envisage attack of the $-\overset{1}{\text{CH}_2}-\overset{2}{\text{CMe}}:\overset{3}{\text{CH}}-\overset{4}{\text{CH}_2}-$ group which is common to rubber and the diolefins at positions (1) or (4) with the initial removal of a hydrogen atom from the α -methylene carbon atoms. The radical formed by removal of a hydrogen atom from (1) could by resonance cause the double bond to move to the left. In this new position the double bond would still be of type CRR':CHR' and would be expected to absorb at the usual 12.0μ position. However, removal of the hydrogen atom from (4) would give rise to a radical which could move the double bond to the right and thus give rise to CHR:CHR' groups, and hence to a band at 10.4μ in the final product.

The work described above on the vulcanisation and degradation of rubber will be published in more detail later. We should like to express our thanks to Dr. E. H. Farmer and Dr. R. F. Naylor for helpful discussions on the above points.—THE LABORATORY OF COLLOID SCIENCE, CAMBRIDGE. [Received, March 24th, 1947.]

The Ernst Julius Cohen Memorial Lecture.

DELIVERED BEFORE THE CHEMICAL SOCIETY ON OCTOBER 2ND, 1947.

By F. G. DONNAN, C.B.E., D.Sc., LL.D., F.R.S.

AMONGST the distinguished Dutch men of science of the generation that is now passing, or has already passed, away, a very high place must, by universal consent, be assigned to the subject of this Memoir. It would be no exaggeration to say that the name, and very often the personality, of Ernst Cohen have been known to students of chemistry and physics throughout the world for nearly fifty years. His famous researches in the fields of polymorphism, electrochemistry, thermochemistry, and piezochemistry, the excellent books he wrote, his many visits to other countries and the lectures he gave therein, and—last but not least—the important part he played in the national and international organisation and development of chemical science, made Ernst Cohen one of the most outstanding and well beloved men of science of his day and generation.

He was the devoted pupil and disciple of the great van't Hoff, and belonged to that famous Dutch school of physicochemical science associated with the names of van't Hoff, Roozeboom, Cohen, and Schreinemakers. Although van't Hoff is, perhaps, best known to students of chemistry for his pioneer work on optical activity and the "tetrahedral carbon atom", the laws of osmotic pressure, and the application of thermodynamics to the study of chemical equilibria and "chemical dynamics", he became interested in the conditions of formation and decomposition of double salts before he left Amsterdam, and during his Berlin period (from 1895 onwards) devoted himself to the study of the formation of oceanic salt deposits. The famous work of Roozeboom on "Heterogene Gleichgewichte" is well known to physical chemists and metallurgists, whilst Schreinemakers, the mathematician and geometer, became the great investigator and exponent of "geometrical" thermodynamics as applied to the transformations and equilibria of heterogeneous multicomponent systems. Broadly speaking, we may say that Cohen took a line of his own, and devoted a large proportion of his researches to the investigation of the polymorphism of one-component systems: the conditions of equilibrium, the transitions, and the stable and metastable states of the various solid (crystalline) modifications of chemically pure substances, especially the elements. His work was characterised by the use of exact electrochemical and thermochemical methods, and by the study of equilibria and transformations at high pressures (up to 1500 atmospheres). Apart from these extensive "piezochemical" researches, he made a long-continued and intensive study of electrochemical thermodynamics, especially in relation to the study of standard galvanic cells (so-called "normal elements").

Ernst Cohen may well be regarded as the greatest of the disciples of van't Hoff. His thesis for the doctorate in Amsterdam under van't Hoff (1893) was probably the starting point, perhaps indeed the fundamental stimulus, of much of his subsequent research work. It was entitled "The Electrical Method of determining Transition-points and the Electromotive Force of Chemical Reactions". If under a given external pressure a chemical reaction be conducted isothermally and reversibly it will yield the maximum external work possible under these conditions. This maximum work, according to van't Hoff, measured the "affinity" of the reaction. Hence the importance of determining the reversible E.M.F. of a galvanic cell in which a chemical reaction occurs isothermally and reversibly, for in this case the maximum work per unit reaction can be calculated. So in his thesis for the doctorate Cohen entered the field of electrochemical thermodynamics, a subject which he developed throughout a long series of researches and which underlay his very important and detailed work on standard cells and other galvanic combinations. It may not be unnecessary to remark that, as probably every student knows now-a-days, the fundamental principles of electrochemical thermodynamics were established by Willard Gibbs in the period 1876—78. We may indeed say that the general *physical* theory underlying the researches of Cohen on the polymorphism and equilibria of solid phases of one-component systems and on galvanic cells, namely the principles of thermodynamics as applied to heterogeneous systems (*i.e.*, multi-phase systems), were established by Willard Gibbs. It is well known that van der Waals directed the attention of Roozeboom to this earlier work of Gibbs, and it is also well known that this indebtedness of the famous Dutch school has been very generously acknowledged. Needless to say, in mentioning the work of Gibbs there is no intention to underrate in the slightest degree the originality and the great scientific value of the work of van't Hoff, Cohen, Roozeboom, and Schreinemakers.

ERNST JULIUS COHEN.

[To face p. 1700.]

Ernst Julius Cohen was born in Amsterdam on March 7th, 1869. It is in the highest degree probable that he would, in normal circumstances, be alive to-day. But, alas, the circumstances were terribly and horribly abnormal. Owing to the fact that he was a man of Jewish descent, it is now a practical certainty that he was foully murdered on or about March 5th, 1944, in a gas chamber at the "extermination" camp of Auschwitz. Concerning this tragic event something more will be said at the conclusion of this Memoir.

Chemistry was in his blood, for his father, Jacques Cohen, born at Düsseldorf in 1833, studied under Liebig at Giessen and afterwards under Bunsen at Heidelberg, where in 1853 he obtained his doctorate in chemistry. Having held posts in technical chemistry at Brussels and Amsterdam, Dr. Jacques Cohen, together with several friends, formed in 1864 the "Company for Chemical Industry" (the Netherlands Coal Tar Distillery), of which he remained Director until his death in 1881. He married in 1863 Johanna Rosenthal, a native of Hanover. Both Jacques Cohen and his wife became Dutch by naturalisation. Ernst Julius was the third of their children.

At the secondary school (Hoogere Burgerschool) in Amsterdam the young Ernst studied chemistry and took a great interest in photography, for which the summer holidays, often spent with his parents in Switzerland, gave him plenty of opportunity. His earliest publications dealt with subjects relating to the art and science of photography. After the school "passing-out examination" came the preparation for the State examination giving access to the University. During this period he was fortunate to obtain excellent private lessons in Latin and Greek from Dr. J. S. Speyer, teacher at the Amsterdam Gymnasium (higher secondary school) and later Professor at Leiden University. This classical and literary training was invaluable to him in later years. In June 1888 he passed the State examination and was then able to devote himself to the study of the exact sciences at the University. The lectures of van't Hoff, van der Waals, and Korteweg particularly attracted him, and with Dr. Ch. M. van Deventer (one of van't Hoff's assistant) he made an investigation of heats of solution. Having passed the "Candidate Examination" in 1890 he went, on van't Hoff's advice, to Paris and worked for a short time in the laboratory of Moissan (then very famous for his isolation of fluorine in 1886). Armed with introductions from van't Hoff, he also visited Berthelot, Pasteur, and Gabriel Lippmann, and saw something of their work and their laboratories. Professor Marey also showed him his photographs of animals in motion. Returning to Amsterdam, he soon afterwards spent some time at the State Agricultural Experimental Station at Breda, where he acquired valuable experience in analytical chemistry. Then came the preparation for the "Doctoral Examination" at the University and attendance at the senior lectures of van der Waals and van't Hoff. This examination was successfully passed in November 1892.

The young candidate for the Doctorate had now to choose the subject for his Doctor thesis. Apparently his reading of van't Hoff's "*Études de Dynamique Chimique*" induced him to request of his prospective sponsor permission for an investigation of the electromotive force resulting from a chemical reaction. Van't Hoff agreed—but with a warning about the difficulties. However, all went well in the end, and on November 8th, 1893, Cohen attained the doctorat in chemistry with honours. The title of his thesis has already been given (see p. 1700).

With his appointment as a demonstrator in van't Hoff's laboratory, there now began a very strenuous period of teaching and research, lasting nine years. Shortly after graduation he married Miss Louise Gompertz, who greatly contributed to the happiness of his home life and the efficiency of his University work. Van't Hoff's new laboratory at Amsterdam became a very active centre of research. In the old laboratory Arrhenius and Meyerhoffer were already working, and to the new laboratory came many men whose names became well known in chemical science—W. D. Bancroft, H. C. Jones, R. Löwenherz, V. Rothmund, and J. Verschaffelt.

Ernst Cohen soon became a Lecturer (Privat Dozent) and a very active and successful investigator. In collaboration with Bredig and van't Hoff he continued the work on "transition elements", and published several papers on subjects related to his interest in photography, e.g., the action of hydrogen on silver bromide gelatine plates; the solubility of silver halides in various solutions; the supposed influence of gelatine on the double decomposition of salts.

A great change came in the Amsterdam laboratory when, in 1895, van't Hoff resigned, and was succeeded by Bakhuis Roozeboom. Cohen now took a much greater part in the lectures on physical chemistry, but this did not interfere with his output of research. Besides work on the decomposition of arsine and on the ionisation of substances in alcohol-water mixtures, his famous series of investigations on the allotropic modifications of tin began, at first in collaboration with van Eijk, whose attention had been drawn to this problem by Roozeboom.

Cohen's reputation as a physical chemist had now risen so high that in 1898 he was offered

the Chair of Physical Chemistry at McGill University in Montreal. He was, however, so happy in Amsterdam and his relations with Roozeboom were so friendly that he declined the honour. In 1901 he became "extraordinary" Professor of Chemistry in the University of Amsterdam, with special reference to Physical Chemistry.

His reputation as a physical and inorganic chemist was now established, with the result that in 1902 he was appointed to the Professorship of Inorganic and General Chemistry at the University of Utrecht. At first he had to occupy the old and very inadequate laboratory which dated from the time of G. J. Mulder. But he had accepted the Chair at Utrecht on the condition that a new laboratory should be built. The new and excellent laboratory, built to his own designs and named the van't Hoff Laboratory in honour of his great teacher and inspirer, was opened on May 18th, 1904, with van't Hoff himself as the guest of honour.

Now began the great period of his life as Professor at Utrecht and Director of the van't Hoff Laboratory, a period which lasted until his retirement in 1939. During this period of thirty-five years he built up one of the world's great centres of teaching and research in physical chemistry. However, it might have happened that Utrecht soon lost Cohen, for, after he had been only five years there, Roozeboom died (1907), and the Professorship at Amsterdam became vacant. It was offered at first to Schreinemakers, who declined. Then the invitation came to Cohen. But he was so happy in his new laboratory and amongst his new colleagues that he also declined the honour.

A very large proportion of the researches in Utrecht due to Cohen and his collaborators and students dealt with the polymorphism of substances, both elements and compounds. The work on tin, begun in Amsterdam, was continued and much developed. This is perhaps the most famous of all his investigations. It had been known before his time that certain organ pipes made of tin in the old castle church at Reitz had largely crumbled into a grey powder during a cold winter (as reported by G. L. Erdmann in 1851), and Fritzsche in 1869 had described a case where blocks of Banca tin had similarly "decayed" in the store of a custom house in Russia. These extraordinary phenomena were explained by Cohen, who showed that they were due to the transformation of ordinary "white" tin into another modification, "grey" tin. By dilatometric and other methods he found the transition temperature to be 18° (corrected later to 13.2°). Below this equilibrium temperature, ordinary white tin is unstable with regard to the stable modification, *i.e.*, the grey tin. But under ordinary conditions the change does not occur, the white tin being then "metastable". The change may, however, be greatly accelerated by various means, *e.g.*, lowering of temperature, presence of certain solvents, "inoculation" with grey tin, etc. Cohen drew attention to the fact that objects of tin kept in museums sometimes develop warty "intumescences", owing to the gradual and local onset of the change to grey tin. He called this the "museum disease", and such changes became celebrated as the "tin disease".

The next case he investigated was the phenomenon known as "explosive antimony". If a concentrated solution of antimony chloride in water (plus some hydrochloric acid) be electrolysed with an antimony anode and a platinum cathode, the metallic deposit on the cathode, if scratched or struck, shows a sudden large evolution of heat, accompanied by clouds of white fumes. Cohen showed that this phenomenon is due to the fact that the original metallic deposit is an unstable (*i.e.*, metastable) modification which changes with evolution of heat to a stable modification, the clouds being caused by the volatilisation of occluded antimony chloride.

He was now well embarked on his great series of investigations of the "physical metamorphosis" (as he called it) of solid substances. In the case of tin, the grey tin is (at ordinary atmospheric pressure) stable below the corresponding transition temperature, the white tin stable above it. This is a case of *enantiotropy*, the two forms being *enantiotropic*. In the case of antimony, one modification has no temperature region of true stability (always metastable). This is an example of *monotropy*. In a long series of researches these phenomena of polymorphism of solid (crystalline) substances were investigated in numerous instances—phosphorus, tellurium, cadmium, bismuth, zinc, copper, the "explosive" platinum metals of Bunsen, lead, silver, potassium, sodium, antimony iodide, cadmium iodide, silver iodide, thallous picrate, ammonium nitrate, etc.

Special attention was paid to the existence of metastable phases and to their usual formation under conditions where the stable ones would be "thermodynamically" expected. The phenomena of both enantiotropy and monotropy were found to be exceedingly common amongst both elements and compounds. From 1909 onwards a series of papers entitled "The metastability of our metal world on account of allotropy, and its significance for physics, chemistry, and technology" were published by Cohen, who had gradually come to the conclusion that most

metals in common use were, if not entirely metastable, at least mixtures of stable and metastable forms (phases). The same thing applied to the majority of solid non-metallic substances. He was also forced to the conclusion that the well-known tables of physical constants, *e.g.*, density, specific heat, etc., contained unreliable data owing to the *physical* "impurity" of solid chemically pure substances.

Reference may be finally made to Cohen's investigations of what he called the "strain disease". Cold working, especially polishing, of metals produces, according to him, metastable conditions as a result of partial disruption or deformation of crystalline structures and the formation of "amorphous" states which, owing to vibration or other causes, are liable to a sort of "recrystallisation", *i.e.*, reversion to the stable crystalline state (compare the "flowed" state of Beilby). Hence the technically troublesome phenomenon of "season cracking".

In his work on the transformation of solid substances from one stable phase to another one, stable at higher temperatures, a very characteristic feature of Cohen's researches was the employment of what he called "transition elements". Various types of such galvanic cells were used, of which a few examples may be mentioned here. If the E.M.F. of the cell

Metal <i>M</i> in the <i>stable</i> solid phase	A solution of a salt of <i>M</i>	Metal <i>M</i> in the <i>metastable</i> solid phase
--	-------------------------------------	--

be measured at a constant pressure but at different temperatures, it will have a zero value at the transition temperature (equilibrium temperature). The transition cell

Metal <i>M</i> in the <i>stable</i> solid phase	A solution of a salt of <i>M</i>	An amalgam electrode of the metal <i>M</i>
--	-------------------------------------	---

will show a break in the curve relating E.M.F. to temperature at the transition temperature, provided that the amalgam suffers no change of condition (such as a change from a purely liquid to a heterogeneous state, or vice versa), and that the phase change of *M* is not retarded.

The cell (analogous to the standard Clark cell)

Zinc amalgam	Saturated solution of $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$ in contact with the solid salt	$\text{Hg}_2\text{SO}_4 \cdot \text{Hg}$
--------------	---	--

will show a break in the E.M.F.-temperature curve when the solid heptahydrate changes to the solid hexahydrate.

A study of galvanic cells led him to a long series of researches on the electrochemistry of the standard Clark and Weston cells, including also the Daniell cell and the calomel cell of Lipscomb and Hulett. A close and accurate investigation of all the actions occurring in such cells and the conditions of stability or metastability of all the phases present, whether solid metals, metallic amalgams, or solid salts, led to great and important advances, including, for example, the demonstration that the standard Weston cell (as then employed) was quite unreliable. This close and accurate analysis enabled him to determine with high precision the various quantities occurring in the Gibbs-Helmholtz equation. His work in this field was indeed a most valuable contribution to electrochemical thermodynamics.

An important part of the researches carried out in the Utrecht laboratory by Cohen and his collaborators concerned the effect of pressure on the reactions and equilibria occurring in condensed (liquid and solid) systems. To this branch of chemical science he gave the name "piezochemistry". An account of the work carried out in this field up to 1914 was published by Cohen and Schut in a book entitled "*Piezochemie kondensierter Systeme*" (Leipzig, 1919). This valuable work contained detailed references to the existing scientific literature. An excellent and detailed account of his researches in piezochemistry (up to 1925) can be found in his book entitled "*Physico-chemical Metamorphosis and some Problems in Piezochemistry*" (McGraw Hill, 1928), which contains the twenty-one lectures which he delivered at Cornell University as the George Fisher Baker Non-Residential Lecturer (1925-26). It may be said in passing that anyone wishing to obtain a first-hand and detailed account of Cohen's principal fields of research may be referred to this book.

The elaborate high pressure apparatus constructed in the Utrecht Laboratory enabled measurements to be made up to 1500 atmospheres. A mere enumeration of the principal types of effects which were studied will indicate the extent of this work. These included the effect of pressure on: (1) rates of chemical reaction; (2) transition temperatures of solid phases; (3) electromotive force of galvanic cells; (4) solubilities of solid substances; (5) Faraday's first law; (6) velocity of diffusion in liquid systems; (7) viscosity of liquids; and (8) electrical conductivity of solutions. So great was the extent and detail of these investigations that only a few remarks

can be made on an occasion such as the present. The rate of inversion of sucrose at 25° in an aqueous hydrochloric acid solution was found to be reduced by about 26% when the pressure is increased from one to 1500 atmospheres. In the hydrolysis of ethyl acetate by sodium hydroxide in aqueous solution a rise of pressure from one to 1500 atmospheres increased the reaction-velocity constant by 37%. In these and other similar cases of reaction-velocities the measured effects could not be related to thermodynamical equations dealing with equilibrium states. In the case, however, of transition temperatures of solid phases, use could be made of the well-known Clapeyron equation

$$\frac{dT}{dp} = \frac{T(v_2 - v_1)}{q},$$

where $v_2 - v_1$ denotes the volume change, T the transition (equilibrium) temperature, p the pressure, and q the corresponding heat absorption. In connection with the effect of pressure on solubility, Cohen was able to relate his experimental data to the thermodynamical equation known as "Braun's law", namely

$$\left(\frac{\partial x}{\partial p}\right)_T \bigg/ \left(\frac{\partial x}{\partial T}\right)_p = -T\Delta v/Q,$$

where x denotes the solubility (as moles of solute in a given mass of solvent). On the right-hand side of the equation, Δv denotes the so-called "fictitious" volume change, *i.e.*, that corresponding to the solution of one mole of the solute in a large quantity of the saturated solution at T and p , and Q the corresponding amount of heat absorbed under such conditions, *i.e.*, the "fictitious heat of solution". These fictitious quantities are simply the *limiting* values approached as the concentration of the solution approaches the saturation (equilibrium) value at the given p and T . A fuller and more precise discussion of these matters and a mathematical proof of Braun's equation would have been desirable, but the foregoing remarks must suffice for the purpose of indicating the general nature of Cohen's work in this particular field of investigation.

The measurement of the effect of pressure on the E.M.F. of a reversible galvanic cell at constant temperature enabled Cohen to ascertain the effect of pressure on the "affinity" (in the sense of van't Hoff's definition) of the chemical reactions occurring in the cell, and led him to a very interesting series of investigations (which included measurements of the effect of pressure on the Clark and Weston cells and the lead accumulator). In connection with his work on the effect of pressure on diffusion velocity, a brief reference may be made to the potentiometric measurement of the rate of diffusion of cadmium into mercury. It was found that the velocity of diffusion of cadmium into mercury at 20° is reduced by 5% on application of an external pressure of 1500 atmospheres. Measurements of the viscosity of mercury (at 20°) at pressures of one atmosphere and 1500 atmospheres led Cohen to the conclusion that the product of the diffusion velocity and the viscosity is equal to a constant *independent* of the pressure. Finally, it may be mentioned that he proved experimentally that the electrical charge of an ion in solution is unchanged by an increase of pressure up to 1500 atmospheres.

This brief sketch of some of the main lines of investigation carried out by Cohen and his collaborators might be much extended, did space permit. For example, much excellent calorimetric work on specific heats of solids and solutions and on heats of solution deserves mention, especially the very interesting investigation on the (negative) heats of solution of the various polymorphic forms of cadmium iodide, and their mixtures, which was made possible by the use of a specially constructed and very accurate form of electrical adiabatic calorimeter. Many other lines of work would be worthy of discussion, but the mere mention of a few of them must suffice: osmotic pressure and its measurement; corrosion of metals; effect of traces of water on equilibria in solutions, and superheating in relation to the intensive drying of liquids; influence of dispersity on solubility and physico-chemical constants; velocity of polymorphic changes and the influence of mechanical deformation; polymorphy of ice at one atmosphere pressure.

A very characteristic part of the many activities of Ernst Cohen was due to his deep interest in the history of science, especially, of course, chemical science. Anyone visiting his laboratory or his home was at once struck by the abundance of old prints relating to personalities and events of interest or importance in this history. In his own country he was the moving spirit in the establishment of the historical Committee of the Dutch Chemical Society and the formation of its valuable historical library. He was also one of the founder members of the Dutch Society for the History of Medicine, Natural Sciences, and Mathematics, becoming its Chairman in 1916. A long series of "chemical-historical" articles and notes in the *Chemisch Weekblad* bear ample

witness to his activity in historical research, as do also various books, namely one on the history of "laughing" gas, one on Herman Boerhaave, and his great book on the life and work of van't Hoff.

For a man so actively engaged in the laboratory, his scientific-literary output of books was quite remarkable. In addition to those to which reference has been made, the following may be mentioned: "Studien zur chemischen Dynamik" (an enlarged edition of van't Hoff's "Études de Dynamique Chimique"); Monograph on Tin in Abegg's "Handbuch der anorganischen Chemie"; two textbooks for medical students, one on physical chemistry, and one (with van Romburgh) on inorganic chemistry.

In the field of national and international organisation and co-operation in science, Ernst Cohen took an active and distinguished part. He was a member of the original executive Committee of the Dutch Chemical Society (founded in 1903), and became its first President. He took a very active share in the work of this Society, becoming President again ten years afterwards and finally Honorary President. Elected a member of the Royal Netherlands Academy of Sciences in 1913, he did much to promote the scientific work, organisation, and prestige of this famous Academy. He became a member, and subsequently Chairman, of the Dutch Committee on Coinage. In the international field he took an active part as a member of the Council of the International Union of Pure and Applied Chemistry, becoming President of the Union in succession to Sir William Pope. For many years he was a valuable member of the International Committee responsible for the annual tables of physical and chemical constants. It is no exaggeration to say that as time went on he became one of the great cosmopolitan representatives of chemical science. Invitations to give lectures came to him from many countries. These lectures were very successful, for he was not only a good lecturer but a good linguist, speaking fluent English, French, and German. In this country he delivered the Kamerlingh Onnes and Messel lectures, and also a number of other lectures during his frequent visits to London, Oxford, and Cambridge. Perhaps the most famous—certainly the most extensive—visit was one to Cornell University in the second semester of 1925—26, when he gave a course of twenty-one lectures, as Non-Resident Lecturer in Chemistry on the Baker Foundation. Besides such invitations for special lectures, he took part on various occasions in the meetings of the Faraday Society, the German Bunsen Society, the German Naturforscherversammlung, and many similar societies. So high indeed was his position in the esteem of chemists throughout the world that it would scarcely be possible on the present occasion to enumerate the many invitations he received to visit various countries for special ceremonies. Perhaps it may be permissible to make one exception, namely his visit to Liverpool in 1906 on the occasion of the opening ceremonies of the Muspratt Laboratory of Physical and Electro-Chemistry.

Honours came to him from many countries. It is pleasant to remember that in this country he was elected a Foreign Member of the Royal Society, an Honorary Fellow of the Chemical Society, and an Honorary Member of the Royal Institution.

One of the greatest things Cohen did in the cause of international friendship and co-operation was the famous meeting at Utrecht in the summer of 1922. When staying with Donnan in 1920, the suggestion was made by the latter that it would be a fine thing if an international meeting of chemists could be held in some "neutral" country, preferably Holland. This idea was eagerly taken up by Cohen, who, ably assisted by his colleague, Professor van Romburgh, formed a small international Committee to discuss the matter. This Committee, consisting of E. Biilmann (Copenhagen), G. Bruni (Milan), Victor Henri (Zürich), R. Schenck (Münster), Paul Walden (Rostock), and R. Wegscheider (Vienna), together with Cohen, van Romburgh, Kruyt, and Donnan, met at Cohen's house in 1921. Invitations to 100 chemists in many countries were issued in March 1922, and the great Reunion was held at Utrecht during June 21st—23rd, 1922. Unfortunately, no Belgians or French were present, but from Germany came Bodenstein, Bredig, Hahn, Pfeiffer, Schlenk, Schenck, Stock, Walden, and Wieland. Cohen opened the meeting with words of warm welcome (in five languages), many scientific lectures were held, and magnificent hospitality was provided by our generous Dutch hosts. The Utrecht Reunion was a great success, and a very splendid and noble deed in the cause of international friendship on the part of Dutch men of science.

Ernst Cohen was a man of firm and sincere character, who had many friends in the world of science. The writer of this Memoir met him first in 1904 and was privileged to enjoy his friendship for thirty-five years. His equable and kindly, though serious, temperament, his dry wit and good-natured humour, his constant regard for the wishes and wants of others—all these qualities endeared him to his friends. He was very methodical and systematic in his ways of life, which was one of the secrets of his huge accomplishment of work. He was thrice married,

and is survived by his third wife, née Miss W. A. T. de Meester (now Mrs. van Ginneken-de Meester). His friend and colleague, Professor H. R. Kruyt, has written an appreciation of Cohen's personal qualities as a University teacher and director of research. He possessed in high measure the power of inspiring and guiding his research students and collaborators. Great freedom of thought and initiative were encouraged by the director, but if necessary one had to defend one's point of view by reasoned argument. The result was a happy and co-operative band of successful workers. So great was the number of his research collaborators and assistants that only three can be mentioned here, namely, Miss W. A. T. de Meester (who later became his wife), H. R. Kruyt, and A. L. Th. Moesveld. As is well known, H. R. Kruyt later became a University Professor and colleague of Cohen at Utrecht, and created in the van't Hoff laboratory a famous school of teaching and research in colloid chemistry.

The tragic end of Cohen's life has been described by Kruyt in the *Chemisch Weekblad* (1945, 41, 126—128). In 1941 his property was seized and in April 1942 his house was taken for German officers, but fortunately friendly neighbours took Cohen and his wife into their house. In May 1942 he was obliged to wear the "yellow star" and became subject to the restrictions imposed on Jews. Matters came to a head in 1943, when on a visit to the laboratory he was arrested and taken to a prison in Amsterdam, the charge being that he had entered a "public" building. The many efforts of his friends to secure his release were unavailing, and Cohen was sent to the concentration camp at Vught in Holland. At a discussion of this state of affairs by the Council of the Dutch Chemical Society, it was proposed by Dr. Kappelmeier that an approach be made to the S.S. authorities at the Hague. This was successful, Cohen was released, and soon afterwards was freed from practically all the restrictions imposed on Jews. But the enemies of the Jews had not yet finished with him. On February 28th, 1944, a friend, having found out that an order for his arrest had come from Amsterdam to the Utrecht police, telephoned Cohen, who then, on good advice, moved to another friend's house (thus evading immediate arrest), and when night fell came to see Kruyt. Kruyt advised him strongly to "dive", and so give his many friends time to approach the German headquarters at the Hague. But this he refused to do, maintaining that he had done nothing wrong and that the whole affair must be due to some misunderstanding. Moreover, he refused Kruyt's advice to approach the S.S. headquarters at the Hague himself. Instead, he informed the Utrecht police of his whereabouts, was arrested and taken to Amsterdam, and on March 1st to Westerbork. Here further efforts were made by his friends to induce him to approach the Hague, but all in vain. The end was now not far off. All the evidence goes to show that on March 3rd he was transported (with many others) to the notorious "death" camp at Auschwitz and there murdered in a gas chamber. It is only fair to say that the good treatment Cohen received at the Hague was due to a certain Fräulein Slotke and her chief, Zöpf, who stood next in rank to Rauter. But towards the end of February 1944 Zöpf was not in Holland! So the enemies of Cohen seized their chance. As regards Cohen himself, Kruyt's opinion was that the shock of the earlier events had shaken his morale and enfeebled his judgment. It seems very probable that if he had taken Kruyt's good advice, his many friends would have safely hidden him until Zöpf returned to the Hague, and so saved his life.

So was murdered by some Nazi criminals the man who had worked in the friendliest co-operation with German men of science for fifty years, the man who had published a large proportion of his scientific work in the German language, the man who had organised the "Peace of Utrecht".

In conclusion, I express my sincere thanks to Professor H. R. Kruyt who kindly supplied me with a number of reports on the life and work of Ernst Cohen. I am also much indebted to Dr. S. Coffey and Mr. Francis Bolam for help with translations from the Dutch originals.

OBITUARY NOTICES.

HARRY THORNTON CALVERT.

1878—1947.

HARRY THORNTON CALVERT was born on May 3rd, 1878, in Leeds, Yorkshire, where he received his early education before proceeding to the Yorkshire College, now the University of Leeds, to study in the Honours School of Chemistry. Though only twenty years of age at the time of graduation in 1898, he had shown such promise as a student that he was at once awarded an 1851 Exhibition, and spent the next three years at the University of Leipzig, where he took the Ph.D. degree. His research at Leipzig was concerned with the dielectric properties of hydrogen peroxide.

After returning from Leipzig, Calvert was for a short time a demonstrator in chemistry under Professor Arthur Smithells at the University of Leeds. He then moved to Hull to serve as Chemist to Messrs. Reckitt & Sons, where he obtained valuable experience in chemistry applied to industry and an insight into industrial problems from many angles.

In 1903 he was appointed Chemist to the West Riding of Yorkshire Rivers Board, a joint committee of the Local Authorities of the area, which had been formed to administer the Rivers Pollution Prevention Acts. This change marked the beginning of his interest in the problems of water supply, sanitation, and prevention of river pollution. Calvert and Maclean Wilson, who was then Chief Inspector of the Rivers Board, proved to be ideal partners in guiding this important work. They were not inspectors in the narrow sense relying on legal authority: they studied in detail the problems with which the managers of local sewage works and industrial concerns were confronted in the disposal of waste liquids, and assisted in finding practicable methods of overcoming the difficulties, while at the same time having in mind the need to decrease the pollution of the local rivers, some of which were in a deplorable condition. It was after some years together on this work that Wilson and Calvert collaborated in writing the book "Trade Waste Waters—Their Nature and Disposal", which has long been accepted as the authoritative work on the subject. Calvert's outstanding investigations in this field were recognized in 1915 by the award of the degree of D.Sc. of the University of Leeds.

During the First World War, he was released on loan to the Department of Explosives Supply of the Ministry of Munitions. In his work in this Department, the wide knowledge he had acquired of a variety of chemical and other industries was of great value, and his success led to the award of the M.B.E.

In 1920 Calvert took up a new appointment as Chemical Inspector of the Ministry of Health, a post which gave him great scope for using his wide scientific and technical knowledge and his sound judgment. When the Water Pollution Research organization was established in 1927 under the Department of Scientific and Industrial Research he was the obvious choice as Director of Research, and he carried this responsibility while continuing his work for the Ministry of Health. With characteristic thoroughness, he steadily built up the work of the Water Pollution Research organization on a sure foundation. Every investigation, whether in the field of fundamental research in University Departments or in the nature of development work with large-scale installations in industrial establishments, was carefully planned before it was undertaken. Calvert was not interested in grandiose and costly schemes sketchily planned; and in consequence few research organizations can claim so much achievement in relation to the expenditure incurred as the Water Pollution Research organization. In all this work he had the full support of every member of the Research Board, for he had the power of inspiring interest and enthusiasm in all concerned, and in unobtrusively getting Boards, Committees, and staff working together amicably and efficiently.

On the outbreak of the Second World War in 1939 he was seconded to the Ministry of Supply as Deputy Controller of Sulphuric Acid, which post he retained until his retirement early in 1947 for reasons of health.

He will be remembered in his profession as an authority in the field of water supply and sanitation, not only in Great Britain, but throughout the world. Kind of heart and always ready to help, he made many close friends here, on the Continent, and in America.

In addition to his many scientific and technical papers and addresses in Great Britain, including chapters in the *Applied Chemistry Reports* and a Chadwick Public Lecture in 1926, Calvert was invited to give the Sedgwick Lecture in 1940 at the Massachusetts Institute of Technology, but owing to the war was unable to deliver the lecture. In 1944, he received the

Kenneth Allen award of the American Federation of Sewage Works Associations. He took a great interest in the Institute of Sewage Purification, of which he was President in 1927, 1928, and 1939. He was also a prominent Fellow of the Royal Sanitary Institute and of the Institution of Sanitary Engineers, a Professional Associate of the Institution of Water Engineers, and a member of the Society of Chemical Industry. He obtained the Associateship of the Institute of Chemistry in 1899 and the Fellowship in 1904, and had been a Fellow of the Chemical Society since April 22nd, 1903.

A. PARKER.

RICHARD CAYLEY GIFFARD MOGGRIDGE.

1915—1946.

RICHARD MOGGRIDGE was born on February 24th, 1915, and educated at Winchester and Balliol College, Oxford. After a short period of research in Oxford he worked until the outbreak of war with Professor Harington at University College Hospital Medical School. During the war he worked first at a Ministry of Supply Research Establishment, and later in other fields of scientific war research. At the end of the war he was appointed to the staff of Messrs. Courtaulds' Research Institute at Maidenhead, but his work there was cut short by his sudden death on March 26th, 1946, at the age of 31.

This bare statement conceals a career of considerable achievement and great promise. Richard Moggridge came to Balliol in 1933, holding both the Frazer Scholarship from Winchester and an open Domus Scholarship. He did not take much part in the social life of the College, but his work in chemistry showed from the very beginning a high standard of all-round achievement, and his essays (written in a minute but beautifully legible hand) were models of accuracy and exposition. His first piece of research was carried out with Dr. A. G. Ogston before he took his degree examination, and dealt with the electrometric titration of vitamin B₁ (*Biochem. J.*, 1935, 29, 866). However, his chief interest was in pure organic chemistry, and his fourth year was spent with Dr. S. G. P. Plant in investigating some structural problems in the indole series (*J.*, 1937, 1125).

He was placed near the top of the first class in his final examination, and left Oxford in 1937 to take up a research post in Professor C. R. Harington's laboratory in the University College Hospital Medical School. His interest in biochemical topics had been kindled by his first piece of research in Oxford, and his chief work in London was also concerned with vitamin B₁, as it dealt with the synthesis of an aminothiazolepropionic acid related to this vitamin. This rather difficult piece of synthetic work was successfully completed (*J.*, 1939, 443), and a later paper on the action of yeast on the synthetic amino-acid (*Biochem. J.*, 1940, 34, 685) is of considerable biochemical interest. As a side issue to this synthetic work Moggridge carried out some experiments in the glutamic acid series (*J.*, 1940, 706), and he also collaborated with Dr. Neuberger in a physico-chemical study of the hydrolysis of methylglucosaminides, which provided contributory evidence as to their structures (*J.*, 1938, 745).

During this period Richard Moggridge showed an increasing grasp of his subject, both in practical skill and in versatility of outlook, and everything pointed to a distinguished scientific career in the future. He was very popular with his colleagues, and happy both in his work and in his marriage to Daphne Simpson, which took place in 1938. When the war came he did not feel justified in continuing with his academic research work, and, after a short period as a full-time air raid warden, in April 1940 he took up a position in the Chemical Defence Research Establishment of the Ministry of Supply at Sutton Oak. His work there involved materials which were mostly unpleasant and often dangerous, but he devoted himself to it with unsparing energy, without regard for comfort or even health. Matters were aggravated by war-time accommodation difficulties, and it seems likely that the strain of this period contributed to his sudden death some years later. His work at Sutton Oak gave rise to a series of post-war publications on derivatives of 2 : 2'-dichlorodiethyl sulphide and related substances (*J.*, 1946, 813, 815, 816, 1105; 1947, 530).

In 1942 he was transferred to a different type of war job, which proved more congenial though no less strenuous. He was engaged on research and development work in connection with the supply of special equipment and arms to underground movements in enemy-occupied Europe. It was often necessary to improvise mines, weapons, explosive charges, special fuzes, and initiating mechanisms at very short notice, and Moggridge was given the responsibility of devising and carrying out such "user" trials as were practicable under these conditions. Risks

had to be taken, but by great thoroughness and attention to detail he succeeded in carrying out an arduous task with conspicuous success. During 1943—45 a constant stream of supplies was provided for various countries, and in France in particular the partisan movement was able to assist materially in the first few critical days after D-day.

In August 1945 Richard Moggridge became Senior Organic Chemist in the newly founded research station of Messrs. Courtaulds, Ltd., at Maidenhead. Here his previous interest in proteins and amino-acids fitted in with fundamental problems of textile research, and he had planned a programme of work for himself and his collaborators. However, he had barely had time to get this work under way when he died, suddenly and unexpectedly, in March 1946 just before his son Robin's third birthday.

Richard Moggridge was liked and respected by all his associates for his integrity of mind and character and his consideration for others. His scientific ability was matched by an interest in many things outside science which grew as he got older. His chief loves were music and climbing, in both of which he was joined by his wife. His knowledge of music was wide, but it was particularly choral music in which he took an active part, first at Winchester and in the Oxford Bach Choir, and later in London and Richmond. His climbing (in the Alps and the British hills) was also much more than a technical accomplishment, being based on a real love of mountain scenery and country people.

The last year of his life contained a new element, which he would certainly wish to be mentioned here. In June 1945 he and his wife joined a group of choral singers at St. Martin-in-the-Fields, and from that time the Christian faith became an increasingly important part of his life. It seems likely that, had he lived, he would have become even more intimately associated with the Church. On April 9th, 1946, his friends at St. Martin's held a choral service there in memory of him, and the beauty and sincerity of that occasion showed how deep an impression he had made among his fellow Christians. One phrase from that service forms a fitting conclusion to this notice: to know Richard was to realise "how possible it is to have at one's side goodness unaware of its good, greatness that honestly believes it is small".

My thanks are due to Dr. C. R. Harington and Professor D. M. Newitt for help in preparing this notice.

INDEX OF SUBJECTS, 1947.

A.

- Acenaphthene series**, 742.
- Acenaphthylene**, photodimerisation of solutions of, 109.
- Acetamidine**, 2-amino-, benzoyl derivative, hydrochloride, and its other hydrochloride, 1374.
- Acetic acid**, nitro-*tert.*-butyl ester, 1518.
6- and 7-nitro-2-naphthyl esters, 331.
vinyl ester, photochemical polymerisation of, 1201.
polymerisation of, radical-sensitised, 1211.
- Acetic acid**, chlorothiol-, dihydromyrcene, *cyclohexyl*, and 2-methyl*cyclohexyl* esters, 138.
phenyl ester, 559.
mono-, *di*-, and *tri*-chlorothiol-, and thiol-, reactions of, 134.
dichlorothiol-, and its dihydromyrcene and *cyclohexyl* esters, 140.
trichlorothiol-, dihydromyrcene, *cyclohexyl*, and 2-methyl-*cyclohexyl* esters, 141.
thiol-, dihydromyrcene, *cyclohexyl*, and 2-methyl*cyclohexyl* esters, 138.
2-nitroethyl ester, 1480.
- N-Aceto-4:5-dimethyldiphenylamide**, 4'-chloro-3-amino-, and its hydrochloride, and 4'-chloro-3-nitro-, 913.
- 2-Acetonaphthalide**, 8-amino-, and 5- and 8-chloro-, 548.
1:7-dinitro-, 1060.
- Acetone**, reaction of, with ammonia, 1394.
- Acetone**, *s*-dichloro-, reaction of, with thiourea, 323.
- 3:4-Acetone α -methylaltrioside**, 2-bromo-, 17.
2-chloro-, 15.
- 3:4-Acetone β -methyl-D-arabinoside**, 2-methane- and 2-*p*-toluene-sulphonyl derivatives, 1343.
- 3:4-Acetone β -methyl-L-arabinoside** and its 2-*p*-toluene-sulphonyl derivative, 1343.
- 3:4-Acetone α -methyl-D-galacturonoside**, methyl ester, 1340.
- 3:4-Acetone 2-methyl α -methyl-D-galacturonoside**, methyl ester, 1340.
- 2-Acetonitrobenzthiazole**, preparation of, 1619.
- 2-Acetonitrobenzthiazole**, *isomeric*-, 1621.
- Acetophenone**, 2:3:4-trichloro-4-chloro-3-amino-, 3-acetyl derivative, 4-chloro-2-nitro-3- and -5-amino-, and 3:4- and 4:5-dichloro-2-nitro-, and their derivatives, 231.
4-chloro-2-amino-, and its 2-acetyl derivative, 4-chloro-2-nitro-, 4-chloro-3- and -5-nitro-2-amino-, and their 2-acetyl derivatives, 235, 236.
3-nitro-2-amino-, and its 2-acetyl derivative, 238.
- β -Acetylacrylic acid**, *p*-nitrophenylhydrazine, 553.
- N-Acetylbenzenesulphonmethyamide**, 387.
- Acetylbenzoic acid**, preparation of, 165.
- 2-Acetyl 4:6-benzylidene α -methylaltrioside**, 3-amino-, 3-acetyl derivative, 20.
- 3-Acetyl 4:6-benzylidene α -methylglucoside**, 2-amino-, 2-acetyl derivative, 21.
- 1-Acetyl-5:5-dimethyl-2-thiohydantoin**, 685.
- 2-Acetyl 3:5-dinitrolyl methylxyloturanoside**, 850.
- Acetylenedicarboxylic acid**, dihydrate, crystal and molecular structure of, 148.
- Acetylenic compounds**, 1578, 1579, 1583, 1586.
- Acetyl furan**, 2-bromo-, 1658.
- O-Acetylhomovanillin**, 2:4-dinitrophenylhydrazine, 1694.
- O-Acetylhomovanillylamine hydrochloride**, 616.
- N-Acetylindoxyl**, 5-bromo-, 609.
- 7-Acetyl-6-methyltetrahydrocarbazole**, 939.
- 1-Acetyl-5:5-cyclopentamethylene-2-thiohydantoin**, 686.
- 3-Acetyl-2-phenylpyrrocoline**, action of Grignard reagents and of iodine on, 670.
- 2-Acetyl-2-phenylpyrrocoline**, 1-iodo-, 672.
- Acetyl rubber**, thiol-, 139.
- Acetylsulphanilamidacetamide**, 1375.
- Acetylsulphanilamidacetamide hydrochloride**, 1375.
- 2-N⁴-Acetylsulphanilamido-4-methylthiazole-5-acetic acid**, and its ethyl ester, and its hydrochloride, 591.
- α -Acetylsulphanilamidothiopropanamide**, 1375.
- 7-Acetyltetrahydrocarbazole**, 6-bromo-, and 6-chloro-, 939.
- β -Acetylthio-*n*-butaldehyde**, and its dinitrophenylhydrazine, 1610.
- β -Acetylthio- β -methyl-*n*-butaldehyde dinitrophenylhydrazine**, 1611.
- β -Acetylthiopropaldehyde**, and its dinitrophenylhydrazine, 1610.
- β -(Acetylthio)propionic acid**, α -chloro-, 1033.
- Acids**, carboxylic, optically-active, esters, action of Grignard reagents on, 436.
dicarboxylic, crystal and molecular structure of, 142, 148, 1145.
polycarboxylic, esters, cyclisation of, 1028.
olefinic, 1030.
- Aconic acid**, and its salts and esters, 1176.
- Acridine**, 5-amino-, nuclear amidino-derivatives, 637.
1:6- and 1:8-diamino-, 596.
1:9-diamino-, and its diacetyl derivative, 1418, 1419.
5-amino-2-cyano-, and 5-chloro-2-cyano-, 638.
5-amino-3-cyano-, and 5-chloro-3-cyano-, 640.
3:7-dichloro-2:8-diamino-, 249.
- Acridines**, synthesis and reactions of, 244.
- Acridines**, amino-, synthesis of, from formic acid and amines, 244.
diamino-, synthesis of, 595.
5-chlorofluoro-, and fluoro-5-amino-, and their derivatives, 759.
- Acridone**, 1:6-, 1:8-, and 1:9-diamino-, 1:6- and 1:9-dinitro-, and 1-nitro-8-amino-, 596.
1:9-diamino-, and 1:9-dinitro-, 1418.
- Acrylic acid**, α -bromo-, reactivity of, 1030.
- 1-Acyl-2:3-dimethylindoles**, Friedel-Crafts reaction with, 1631.
- Address**, presidential, 582, 694.
at Centenary celebrations, 1271.
- Adenosine diphosphate**, synthesis of, 648.
sugar residue in, 355.
- Adenosine-5' benzyl phosphate**, phosphate, and pyrophosphate, and its acridine salt, 650.
- Adrenalinecarboxylic acid**. See β -Phenyl-N-methylserine, β :3:4-dihydroxy-.
- Ætiocholan-17-one**, 3(β):6(β)-dihydroxy-, and its semicarbazone, 814.
- Alanine**, conductivity and viscosity of, 76.
- Alcohols**, *cyclohexane* series, 205.
phosphorylation of, 674.
polyhydric, anhydrides of, 433, 1403, 1405.
primary, reduction of ketones by, 750.
- Alkaloids**, curare, 936.
- Alkanesulphonic acids**, 2-nitro-, preparation of, 1481.
- Alkoxyamines**, 963.
- Alkoxyguanidines**, 963.
- Alkyl cyanides**, ω -amino-, synthesis of, 1369.
2-nitro-, preparation and reduction of, 1500.
3-nitro-, preparation of, 1505.
reduction of, 1508.
halides, reaction of, with trialkyl phosphites, 1465.
- Alkylamines**, 2-chloro-, chemistry of, 513, 519, 527.
2-nitro-, preparation of, 1486.
- Alkylaminocinnolines**, 4-amino-, antimalarial action and synthesis of, 917.
- Alkylaminoquinazolines**, 2-chloro-4-amino-, 779.
- Alkylenedioxydiamines**, 963.
- Alkylenedioxydiguandines**, 963.
- Alkylisotormannilides**, reactions of, 976.
- Alkylphenols**, liquid and solid, spectra of, infra-red, 644.
- Alkylpyrimidines**, effect of substitution in derivatives of, 41.
- Allyl arsines**, phosphines, and stannanes, preparation and properties of, 1446.
- Allylpentabromostannic acid**, 1450.

- Aluminium oxide, alkylation by means of alcohols and, 973.
 thiosulphates, complex, 335.
Aluminium organic compounds :—
 Aluminium alkoxides, alkylation by means of, 973.
 Amides, spectra of, absorption infra-red, 1248.
 Amidines, 382, 390, 394, 497, 1110.
 chemotherapeutic, 82, 84, 87, 690, 738.
 α -Aminoacetamide hydrochloride, 617.
 2-Aminoacridine, 5-amino-, 638.
 3-Aminoacridine, 5-amino-, 640.
 Amidino-alkylarines, preparation of, 618.
 3- and 7-Amino-9-*p*-aminophenylphenanthrenes, and their derivatives, 86.
 Amidino-furans, 396.
 3-Aminofurfuryl alcohol, hydrochloride, 398.
 2-Amino-7-methoxyacridine, 5-amino-, and its hydrochloride, 639.
 3-Amino-7-methoxyacridine, 5-amino-, 640.
 3-Amino-9-methylphenanthridine, and its dihydrochloride, 86.
m-Aminodiphenyl methyl sulphone, thiocyanate, 392.
p-Aminodiphenyl methyl sulphone, 393, 394.
 2-*p*-Aminostyrylpyridine dihydrochloride, 89.
 α -Amino- α -vanillylideneacetamide hydrochloride, 617.
 2-Amidoximinoacridine, 5-amino-, 639.
 2-Amidoximino-7-methoxyacridine, 5-amino-, 639.
 2-Amidoximino-5-phenoxy-7-methoxyacridine, 639.
 Amines, aliphatic long-chain, preparation and properties of, 197.
 aromatic, alkylation of, 973.
 condensation products of ethyl cyclopentanone-2-carboxylate with, 1420.
 reactions of, with *N*-benzenesulphonylbenzothiazolone, 1229.
 reaction of, with phenyl thiocyanates, 816.
 Amino-acids, conductivity and viscosity of, in aqueous solution, 74.
 synthesis of, 1609.
tert-Amino-alcohols, benzilic esters, preparation of, diphenylchloroacetyl chloride as reagent for, 164.
 Aminoalkanes, bacteriostatic action and preparation of, 1419.
 α -Amino-nitriles, reaction of, with carbon disulphide, 1598.
 Ammonia, reaction of, with acetone, 1394.
 Ammonium nitrate III, crystal structure of, 1455.
n-Amyl cyanide, 5-amino-, and its derivatives, 1370.
 2-Nitroethyl ether, 1476.
iso-Amyl dihydromyrcene sulphide, 40.
iso-Amyl-di-*n*-hexylamine oxalate, 200.
iso-Amyl-*n*-hexylamine, and its salts, 200.
m-n-Amyloxyanisole, 104.
 3-Amyloxyphenoxyacetic acid, 104.
n-Amylphosphonic acid, diethyl ester, 1466.
 Analysis, chromatographic, theories of, 1302, 1308, 1315, 1321.
 semimicro-, qualitative, 1347.
 Anhydroacetylavanicin, hydroxy-, acetyl derivative, 1028.
 Anhydroavanicin, and its derivatives, 1027.
 Anhydroavanicin, bromo-, 1028.
 2,3-Anhydro- α -methyl-*l*-ribose, 972.
 Anhydrotetrone acid, structure of, and its derivatives, 1365.
 Aniline, *m*-substituted derivatives, Skraup reaction with, 437.
 Aniline, 2:4:6-tribromo-, and 2:4:6-trichloro-, diazotised, reaction of, with Sandmeyer reagent, 173.
 2,6-dichloro-4-nitro-, deamination of, 734.
 3:5-dicyano-, 83.
 β -Anilino- α -acetamidoacrylic acid, ethyl ester, 101.
 β -Anilino- α -amidino- β -3-methoxy-4-hydroxyphenylpropionamide hydrochloride, 618.
 2-Amino-4-aminoalkylaminoquinazolines, 2-*p*-chloro-, 781.
 1-Anilino-5-anilodimethyl-1:3-pentadienes, hydrohalides, 961.
 1-Anilino-5-anilomethyl-1:3-pentadiene hydrobromides, 961.
 4-Anilino-6-*p*-anisidino-1:3:5-triazine, 2-amino- and 2-chloro-4-*p*-chloro-, 159.
 2-Anilino-7:8-benzoquinoline, 4-chloro-2-*p*-chloro-, 906.
 4-Anilino-6- γ -bisdiethylaminopropylamino-1:3:5-triazine, 2-amino- and 2-chloro-4-*p*-chloro-, 159.
 2-Anilino-4:6-di-*p*-anisidino-1:3:5-triazine, 2-*p*-chloro-, 160.
 4-Anilino-6- β -diethylaminoethylamino-2:5-dimethylpyrimidine, 4-*p*-bromo-, and its dihydrochloride, 1359.
 4-*p*-chloro-, and its dihydrochloride, 1358.
 4-*p*-nitro-, and its dihydrochloride, 1359.
 2-Anilino-4- β -diethylaminoethylamino-6-hydroxy-1:3:5-triazine, 2-*p*-chloro-, 159.
 4-Anilino-6- β -diethylaminoethylamino-2-methyl-5-ethylpyrimidine, 4-*p*-chloro-, and its dihydrochloride, 1360.
 4-Anilino-6- β -diethylaminoethylamino-5-phenyl-2-methylpyrimidine, 4-*p*-chloro-, 1361.
 4-Anilino-6- β -diethylaminoethylaminopyrimidine, 2-amino-4-*p*-chloro-, 1362.
 4-Anilino-2- β -diethylaminoethylaminoquinoline, 4-*p*-chloro-, dihydriodide, 905.
 2-Anilino-6- β -diethylaminoethylamino-4-methyl-1:3:5-triazine, 2-*p*-chloro-, 158.
 4-Anilino-6- β -diethylaminoethylamino-1:3:5-triazine, 2-amino-, 2-amino-4-*p*-chloro-, 2-chloro-, 2:4-di-*p*-chloro-, and 2-chloro-4-*p*-chloro-, and their hydrochlorides, 159.
 4-Anilino-6- δ -diethylamino- α -methylbutylamino-2:5-dimethylpyrimidine, 4-*p*-chloro-, 1359.
 4-Anilino-6- δ -diethylamino- α -methylbutylamino-2-methylpyrimidine, 4-*p*-chloro-, and its dipicrate, 1357.
 2-Anilino-6-diethylamino-4-methyl-1:3:5-triazine, 2-*p*-chloro-, 158.
 2-Anilino-4- γ -diethylaminopropylamino-7:8-benzoquinoline, 2-*p*-chloro-, and its dihydrochloride, 906.
 4-Anilino-6- γ -diethylaminopropylamino-2:5-dimethylpyrimidine, 4-*p*-chloro-, and its dihydrochloride, 1359.
 4-Anilino-6- γ -diethylaminopropylamino-2-methyl-5-ethylpyrimidine, 4-*p*-chloro-, and its dihydrochloride, 1361.
 2-Anilino-4- γ -diethylaminopropylamino-3-methylquinoline, 2-*p*-chloro-, and its perchlorate, 908.
 2-Anilino-6- γ -diethylaminopropylamino-4-methyl-1:3:5-triazine, 2-*p*-chloro-, 158.
 4-Anilino-6- γ -diethylaminopropylamino-5-phenyl-2-methylpyrimidine, 4-*p*-chloro-, 1361.
 2-Anilino-4- γ -diethylaminopropylaminoquinoline, 2-*p*-chloro-, and its dihydrochloride, 905.
 7-chloro-2-*p*-chloro-, 908.
 4-Anilino-6- γ -dimethylaminopropylamino-2:5-dimethylpyrimidine, 4-*p*-chloro-, and its dihydrochloride, 1359.
 4-Anilino-6- γ -dimethylaminopropylamino-2-methyl-5-ethylpyrimidine, 4-*p*-chloro-, and its salts, 1360.
 6-Anilino-2:5-dimethylpyrimidine, 4-chloro-6-*p*-chloro-, 1358.
 4-chloro-6-*p*-nitro-, 1359.
 2-Anilino-4-ethoxyquinazoline, 2-*p*-chloro-, 780.
 6-Anilino-5-ethylpyrimidine, 4-chloro-2-amino-6-*p*-chloro-, and its hydrochloride, 1362.
 4-chloro-2-amino-6-*p*-cyano-, 1362.
 2-Anilino-3-ethylquinoline, 4-chloro-2-*p*-chloro-, 909.
 4-Anilino-6-hydroxy-2-methyl-5-ethylpyrimidine, 4-*p*-chloro-, 1360.
 8-Anilino-6-hydroxy-2-methylpurine, and its hydrochloride, 946.
 2-Anilino-4-hydroxy-6-methyl-1:3:5-triazine, 2-*p*-chloro-, 158.
 2-Anilino-4-hydroxyquinazoline, 2-*p*-chloro-, and its hydrochloride, 778.
 4-Anilino-2-hydroxyquinoline, and 4-*p*-chloro-, 904.
 2-Anilino-*iso*indolinone-3-acetic acid, 2'-bromo-4'-nitro-, and 2:2':6'-dibromo-4'-nitro-, and their methyl esters, 473.
 2:2'-chloro-4'-amino-, and 2:2':6'-dichloro-4'-nitro-, and its methyl ester, 472.
 2:2'-chloro-4'-nitro-, and its methyl ester, 471.
 2:4'-nitro-, 470.
 2:2':4'-dinitro-, and its derivatives, 832.
 2-Anilino-3-methylene-*iso*indolinone, 2-(2':4'-dinitro)-, 837.
 6-Anilino-2-methyl-5-ethylpyrimidine, 4-chloro-6-*p*-chloro-, 1360.
 2-Anilino-4-methyl-1:8-naphthyridine, 7-amino-, and 7-amino-2-*p*-chloro-, and its hydrochloride, 1409.
 Anilinoethylpyrimidines, aminochloro-derivatives, 1357, 1358.
 2-Anilino-3-methylquinoline, 4-chloro-2-*p*-chloro-, 908.
 2-Anilino-4-methylthioquinazoline, 2-*p*-chloro-, 780.
 2-Anilino-4-methyl-1:3:5-triazine, 6-amino-2-*p*-chloro-, and its 6-acetyl derivative, 158.
 2-(β -Anilino- α - and - β -methylvinyl)benzthiazole ethiodides, 958.
 4-Anilino-6-methoxycinnoline, 920.
 2-Anilino-4-phenoxy-6-methylpyrimidine, 2-*p*-chloro-, 790.
 2-Anilino-4-phenoxyquinazoline, 2-*p*-chloro-, 780.
 α -Anilino-phenylacet-*p*-chloroanilide, 1044.
 7-Anilino-4-phenyl-2-methyl-1:8-naphthyridine, 1410.

- 6-Anilino-5-phenylpyrimidine**, 4-chloro-2-amino-6-*p*-chloro-, 1362.
- 2-Anilino-4-isopropylamino-6-ethoxy-1:3:5-triazine**, 2-*p*-chloro-, 160.
- 4-Anilino-6-isopropylamino-1:3:5-triazine**, 2-amino- and 2-chloro-4-*p*-chloro-, 159.
- 6-Anilino-4-isopropylamino-6-ethoxy-1:3:5-triazine**, 4-chloro-2-amino-6-*p*-chloro-, and its hydrochloride, 1361.
- 2-Anilinoquinazoline**, 4-chloro-2-*p*-chloro-, 780.
- 2-Anilinoquinoline**, 4-chloro-, and 4:2-dichloro-, and 4-chloro-2-nitro-, 905.
- 4-Anilinoquinoline**, 2-chloro-, and 2:4-*p*-dichloro-, 904, 905.
- 6-Anilino-1:3:5-triazine**, 2:4-dichloro-6-*p*-chloro-, 158.
- Anilino-vanillyloxyacetic acid**, ethyl ester, 617.
- 2-β-Anilino-vinylbenzelenazole** ethiodide and ethochloride, 958.
- 2-β-Anilino-vinylbenzthiazole**, 5-chloro-, and 6-nitro-, and their derivatives, 957.
- Anionotropic rearrangement**, kinetics of, 1096.
- m*-Anisidine**, 4-cyano-, 440.
- 4-*p*-Anisidino-6-β-diethylaminoethylamino-2:5-dimethylpyrimidine**, and its dihydrochloride, 1359.
- 4-*p*-Anisidino-6-β-diethylaminoethylamino-2-methyl-5-ethylpyrimidine**, and its dihydrochloride, 1361.
- 4-*p*-Anisidino-6-β-diethylaminoethylamino-1:3:5-triazine**, 2-chloro-, hydrochloride, 159.
- 4-*p*-Anisidino-6-γ-dimethylaminopropylamino-2-methyl-5-ethylpyrimidine**, 1361.
- 6-*p*-Anisidino-2:5-dimethylpyrimidine**, 4-chloro-, 1359.
- 2-*o*-Anisidino-5-ethylcyclohex-1-enecarboxylic acid**, ethyl ester, 1038.
- 4-*p*-Anisidino-6-hydroxy-2-methyl-5-ethylpyrimidine**, 1361.
- 2-*p*-Anisidino-4-hydroxyquinazoline**, 2-hydroxy-, 780.
- 6-*p*-Anisidino-2-methyl-5-ethylpyrimidine**, 4-chloro-, 1361.
- 2-*p*-Anisidino-γ-clopent-1-enecarboxylic acid**, ethyl ester, 1037.
- 6-*p*-Anisidinopyrimidine**, 4-chloro-2-amino-, and its hydrochloride, 1362.
- 6-*p*-Anisidino-1:3:5-triazine**, 2:4-dichloro-, 158.
- Anisole**, 3-nitro-4-cyano-, 440.
- 2-*p*-Anisylisoarindoline**, and its derivatives, 666.
- 1-*p*-Anisylbuta-1:3-diene**, and its adducts, 1096.
- N*'-*p*-Anisyl-*N*-diethylaminoethylbenzamidine**, 163.
- N*'-*p*-Anisyl-*N*-diethylaminoethyl-2:4-dichlorobenzamidine**, 163.
- 2-*p*-Anisylidihydroglyoxaline**, and its salts, 500.
- 2-Anisyl-2:3-dihydroreteneoxazole**, 2-hydroxy-, 653.
- 4-*p*-Anisyl-3-methylcinnoline *N*-oxide**, 1651.
- 3-*p*-Anisyl-2-methylindole**, and its picrate, 1652.
- p*-Anisylpropenylcarbinol**, 1096.
- 1-*p*-Anisyl-1:4:9:10-tetrahydronaphthaquinone**, 1096.
- Annual General Meeting**, 702, 867.
- 10-Anthraldehyde**, 9-hydroxy-, anil, 978.
- Anthranilic acid**, 5-chloro-, methyl ester, preparation of, 884.
- Antibiotics**, production of, by fungi, 1021.
- Antimalarials**, new, 678, 1659.
- synthesis of**, related to niquidine, 222.
- synthetic**, 41, 154, 160, 775, 783, 890, 899, 910, 914, 917, 1354, 1613.
- chemistry of**, 1331.
- tetrahydroacridones**, 1034.
- Apple pectic acid**, molecular structure of, 1218.
- Arabinose**, determination of, 1048.
- D*- and *L*-Arabinoses**, derivatives of, 1341.
- 1-*d*-Arabinosidoglyoxaline-4:5-dicarboxamide**, 380.
- 1-*d*-Arabinosidoglyoxaline-4:5-dicarboxamide**, and its 1-tri-acetyl derivative, 380.
- Arachis hypogaea***, araban from, structure of, 1221.
- Aromatic compounds**, kinetics of substitution in, by halogens, 1167.
- reaction of benzoic anhydride with**, catalysed by boron trifluoride, 1237.
- iso*Arasindoline**, 2-chloro-, and 2-iodo-, 667.
- 5-chloro-2-iodo-**, 668.
- Arazines**, cyano-ethylation of, 618.
- Aryl isocyanates**, reaction of, with methyl alcohol, 713.
- 1-Arylalkyl cyanides**, 3-nitro-, preparation of, 1504.
- 4-Arylamino-6-aminoalkylaminopyrimidines**, 1354.
- 2-Arylamino-4-aminoalkylaminoquinazolines**, 775.
- Arylaminoalkylaminoquinazolines**, 899.
- 2-Arylamino-4-aminoalkylaminoquinazolines**, 907.
- 2-Arylamino-4-β-diethylaminoethylaminoquinazolines**, 782.
- 2-Arylamino-ketones**, molecular rearrangement and displacement of arylamine residues in, 1041.
- 2-Arylisoarindolines**, preparation and properties of, 662.
- 4-Arylcinnolines**, *N*-oxides, 1649.
- Aryldiazonium sulphates**, solid, preparation of, 325.
- Arylmethyl cyanides**, reaction of, with *o*-nitro-olefins, 1504.
- Aryloxydialkylaminoalkylaminopyrimidines**, 783.
- Aryl pyridyl sulphones**, synthesis of, 52.
- Arylthiodialkylaminoalkylaminopyrimidines**, 783.
- 9-Arylxanthens**, reactions of, in sunlight, 997.
- Aspergillus clavatus***, clavatul from, 611.
- Atomic weights**, reports on, 980, 983.
- table of**, 988.
- Azamethin [2-(4-methylthiazole)][2-(3-phenyl-4-methyl-2:3-dihydrothiazole)]**, 1658.
- Azamethin[2-(4-phenylthiazole)][2-(3:4-diphenyl-2:3-dihydrothiazole)]**, and its dihydrobromide, 1658.
- bicyclo(3:3:1)-2-Azanonane**, derivatives of, 399.
- 1-Azanthraquinone**, chemistry of, 539, 545.
- 1-Azanthraquinone**, 6-bromonitro-, chloronitro-, and hydroxy-derivatives, 544.
- chloro-derivatives**, 542.
- 1-Azanthraquinonesulphonic acids**, barium salts, and their *p*-chlorobenzyl-*ψ*-thiuronates, 542.
- Azeotropic systems**. See under Systems.
- Azole series**, 1594, 1598.
- 1:1'-Azonaphthalene**, reduction of, 77.
- 1:1'-Azonaphthalene**, 4:4'-dichloro-, and 4:4'-dinitro-, reduction of, 77, 78.
- 2:2'-Azonaphthalene**, 1:1'-dibromo-, 1392.
- Azoxy-3-methyl-2-stilbazoles**, 1699.

B.

 2-Ethoxy-3:6-dimethylpyrazine, and its picrate, 1182.
o-Ethoxyethylideneaminoacetic acid, potassium salt, 100.
o-(*o*-Ethoxyethylideneamino)- β -acetoxyacrylic acid, ethyl ester, 101.
o-(*o*-Ethoxyethylideneamino)- β -hydroxyacrylic acid, potassium ethyl ester, 101.
o-Ethoxyethylideneaminomalonic acid, ethyl ester, 100.
 2-Ethoxymethylpropane-1:3-diol, 2-nitro-, di-*p*-nitrobenzoyl derivative, 1477.
 7-Ethoxy-1:2:3:4-tetrahydroacridone, 1037.
 11-Ethoxythionaphthindole, 657.
 Ethyl β -benzoylpropimino-ether, and its hydrochloride, 1194.
isobutyl sulphide, 2-chloro-, 1515.
 cyanides, 1- and 2-amino-, and their derivatives, 1371.
 2-(*N*-diethylthiocarbamate)ethyl sulphide, 850.
 β -4-methoxybenzoylpropimino-ether hydrochloride, 1195.
nitro-tert.-butyl ether, 1476.
 Ethylamine, 2-hydroxy-, 2-acetyl derivative, and its chloride, 530.
 4-Ethylamino-2'-*N*-benzenesulphonylcarbamyl diphenyl sulphide, and its nitroso-derivative, 1232.
 4-Ethylamino-2-carboxydiphenyl sulphide, and its acetyl derivative, 1232.
 2-Ethylaminothioxanthone, 1233.
 Ethylammonium toluene-*p*-sulphonate, 2-amino-, 502.
 Ethylaniline, 2-nitro-, and its hydrochloride and acetyl derivative, 1488.
p-Ethylaniline, *p*-2-bromo-, hydrochloride, 1572.
 3-Ethyl-2-aniloethylidenebenzoxazoline, 959.
 3-Ethyl-2-aniloethylidenebenzeneselenazoline, 958.
 3-Ethyl-2-aniloethylidenebenzthiazoline, 956.
 3-Ethyl-2-aniloethylidenebenzthiazoline, 5-chloro-, 957.
 3-Ethyl-2-aniloethylidenebenzthiazolidine, 959.
 3-Ethyl-2-anilopropylidenebenzthiazolines, 958.
N-Ethylbenzaminium salts, 385.
 Ethylbenzene, 4-nitro-2':2':2'-trinitro-, and 2:4:6-trinitro-2':2':2'-trinitro-, 1236.
 2-Ethylbenzthiazole, preparation of, and its etho-*p*-toluene-sulphonate, 957.
o-Ethylbenzyl methyl ether, *o*-2-chloro-, and *o*-2-hydroxy-, 1639, 1640.
o-Ethyl- α -*n*-butylacetamidine, and its derivatives, 741.
o-Ethyl- α -*n*-butylacet-*N*-oxylamidines, and their salts, 741.
o-Ethyl- α -*n*-butyl- α -*n*-hexylacetamidine, 741.
 Ethyl-*n*-butyl-*n*-hexylacetoneitrile, 741.
o-Ethyl- α -*n*-butyloctylacetamidines, 741.
 Ethyl-*n*-butyloctylacetoneitriles, 741.
 Ethyl- γ -chloropropylaniline, 311.
 6-Ethyldec-6-en-5-ol, 758.
 3-Ethyl-2-dianiloisopropylidene-6:7-benzbenzthiazoline, 1439.
 3-Ethyl-2-dianiloisopropylidene-1:4-dihydroquinoline, 1441.
 3-Ethyl-2-dianiloisopropylidenebenzeneselenazoline, 1439.
 3-Ethyl-2-dianiloisopropylidenebenzthiazoline, and 5-chloro-, 1439.
 1-Ethyl-2-dianiloisopropylidene-1:2-dihydroquinoline, 1441.
 1-Ethyl-4-dianiloisopropylidene-1:4-dihydroquinoline, 1440.
 3-Ethyl-2-dianiloisopropylidenebenzthiazolidine, 1440.
 Ethylidi-(2-chloroethyl)amine, and its salts, 516.
 Ethyldichlorosilane, 1593.
 2-Ethyldihydro-1:3-benzthiazine-4-one, 764.
 Ethyldi-(2-hydroxyethyl)ammonium salts, 2-chloro-, 529.
 3-Ethyl-2-(3':5'-di-*m*-methoxybenzoyl)-2':4'-dienylidene-benzthiazoline, 1631.
 Ethyldi-*n*-nonylamine hydrochloride, 200.
 Ethyldi-*n*-octylamine, 200.
 Ethyldiisopropylamine, β -chloro-, hydrochloride, 59.
 Ethyldi-(2-isothioureido-8-ethyl)amine, 322.
 Ethylene, halogeno-derivatives, addition of halogens to, 630.
 Ethylenediammonium bistoluene-*p*-sulphonate, 503.
 Ethylenedi-*O*-benzophenone oxime, 968.
 Ethylenediphosphonic acid, tetraethyl ester, 1467.
 Ethylene oxide, anhydro sugars of, action of acid reagents on, 10.
 α , *β* -Ethylene carbinols, alkaline fission of, 756.
 Ethyl-2-ethoxyethylamine, and its picrolonate, 313.
 Ethyl-2-ethoxyethylcarbamyl chloride, 313.
 1-Ethylcyclohexane, 1-nitro-1:2-cyano-, 1507.
 3-Ethylhexane-1-carboxylic acid, 3:2-amino-, 2-benzoyl derivative, ethyl ester, 223.
 3:2-bromo-, and 1:3:2-dibromo-, 224.
 1-Ethylcyclohexene, 1-(1-nitro-2-hydroxy)-, and its 2-acetyl derivative, 1474.
 3-Ethylhexyl cyanide, 3:2-amino-, 2-benzoyl derivative, 223.
 Ethyl- γ -hydroxypropylaniline, 311.
 2-Ethylidenecyanoacetic acid, 1:2-diamino-, 2-benzoyl derivative, ethyl ester, 1375.
 2-Ethylidenemalononitrile, 1:2-diamino-, 2-benzoyl derivative, 1375.
 4-Ethylimino-5:5-dimethyl-2-thiohydantoin, 4:2'-hydroxy-, 686.
 4-Ethylimino-5:5-(3-methylcyclopentamethylene)-2-thiohydantoin, 4:2'-hydroxy-, 686.
 2-Ethylimino-5:5-cyclopentamethylenehydantoin, 2:2'-hydroxy-, 686.
 4-Ethylimino-5:5-cyclopentamethylenehydantoin, 4:2'-hydroxy-, 686.
 4-Ethylimino-5:5-cyclopentamethylene-2-thiohydantoin, 4:2'-hydroxy-, 686.
 Ethylmagnesium bromide, reaction of, with nitro-paraffins, 1492.
 3-Ethyl-2-methylene-6:7-benzbenzthiazoline, 956.
 3-Ethyl-2-methylenebenzeneselenazoline, 956.
 3-Ethyl-2-methylenebenzthiazoline, and 5-chloro-, 956.
 1-Ethyl-2-methylene-1:2-dihydroquinoline, 956.
 1-Ethyl-4-methylene-1:4-dihydroquinoline, 956.
N-Ethyl- γ -methylsulphonylbenzamidine, and its salts, 1112.
N-Ethylmorpholine, 2-hydroxy-, methochloride urethane, 181.
 Ethyl-2-nitroethylaniline, and its picrate, 1489.
 5-Ethyl-3-(2-nitro-2-hydroxymethylbutyl)tetrahydro-1:3-oxazine, 5-nitro-, 926.
 Ethyl-2-nitropropylanilines, hydrochlorides, 1489.
 Ethylpentachlorodisiloxane, 1591.
p-Ethylphenol, *p*-2-bromo-, 1572.
p-Ethylphenyldiallylphosphine, 1448.
p-Ethylphenyldi- β -methylallylphosphine, and its mercuri-chloride, 1449.
p-Ethylphenylmethylidimethyl- β -allylphosphonium iodide, and its mercuri-iodide, 1449.
 Ethylphosphonic acid, 2-bromo-, diethyl ester, 1467.
 Ethylpiperidine, β -chloro-, methiodide, 59.
 2-Ethylpropane-1:3-diol, 2-nitro-, additive compound of, with hexamethylenetetramine, 925.
o-Ethyl- α -isopropylacetamidine, and its hydrochloride, 741.
 Ethylisopropylamine, β -chloro-, hydrochloride, 59.
o-Ethyl- α -isopropyl- α -*n*-hexylacetamidine, 741.
 Ethylisopropyl-*n*-hexylacetoneitrile, 741.
 3-Ethylquinoline, 2:4-dichloro-, 909.
 4-Ethylsulphonylpyridine, 53.
 5-Ethyltetrahydro-1:3-oxazine, 5-nitro-, salts, 927.
N-Ethyl-1:2:3:4-tetrahydroquinoline, *N*-2-nitro-, 1488.
 γ -Ethylthio-*n*-butyronitrile, α -amino-, oxalate, 1612.
 5- β -Ethylthioethylidithiohydantoin, 1612.
 Ethylthiol, 2-nitro-, 1480.
N-Ethylthiomorpholine, *N*- β -chloro- and -hydroxy-, methochlorides, 60.
 6-Ethylthionaphthindole, 6:2-cyano-, 658.
 2-Ethylthio-4-phenylthiazole, and its hydrobromide, 1658.
 β -Ethylthiopropaldehyde *d*-nitrophenylhydrazones, 1611.
 4-Ethylthiopyridine hydriodide, 53.
 Ethyltrichlorotin, 1450.
 α , *β* -Ethyryl ketones, reaction of, with active methyl and methylene compounds, 1626.
 Eugenol, derivatives, sulphonation of, 124.
 Explosives, solid, thermal decomposition of, 1560.

F.

- Flavylum salts, *mono*- and *di*-hydroxy-, 349.
 Fluorescence of aromatic hydrocarbons, quenching of, van der Waals complexes in, 130.
 quenching of, in solvents, 105.

Fluorine organic compounds, with aminoacridines, 759.
Formaldehyde, reaction of, with 1-nitropropane and ammonia, 924.
Formic acid, chloro-, chloroalkyl esters, 178.
Formimidoisopropyl ether hydrochloride, 101.
Formylacetic acid, amino-, acetyl derivative, ethyl ester, 2:4-dinitrophenylhydrazine, 101.
2-Formylethylidene-1-chloro-2-naphthylamine, 2'-chloro-, 543.
6-Formylthionaphthindole, and its picrate, 657.
Friedel-Crafts reaction in carbazole series, 937.
 with 1-acyl-2:3-dimethylindoles, 1631.
d-Fructose, isolation of, from mixed sugars, 1461.
Fungi, antibiotics produced by, 1021.
Furan compounds from sucrose, 396.
Furfuraldehyde, hydrogenation of, to furfuryl alcohol and sylvan, 1068.
Furfuryl alcohol, production of, from furfuraldehyde, 1068.
ca-**Furfurylideneacetophenone**, *p*-amino-, 1420.
 β -2-Furoylpropionic acid, and its ethyl ester, 1194.
 β -2-Furoylpropionitrile, 1194.
2-Furyl β -dimethylaminoethyl ketone cyanohydrin, 1194.
2-(2-Furyl)ethanesulphonic acid, 1-amino-, and 1-nitro-, sodium salt, 1484.
2-(2-Furyl)hexane, 1-nitro-, 1499.
4-(2'-Furyl)-2-methylthiazole, and its hydrobromide, 1658.
4-(2'-Furyl)thiazole, 2-amino-, 1658.
Fusarium jaranicum, antibacterial pigment from, 1021.

G.

Galactose, determination of, 1048.
 α -Galacturonic acid, derivatives of, 1340.
Gallocatechin from green tea, 35.
Gases, adsorbed, redistribution and desorption of, 401.
 heat of adsorption of, on chromic oxide-manganous oxide, 1244.
 streams of, heat exchange between solid granules and, 416.
Geraniolene, sulphide, 1529.
 sulphide methiodide, 1531.
disulphide, 1538.
Gigartina stellata, polysaccharide of, 1622.
Glucose, 3-chloro-, 16.
1-l-Glucosidoglyoxaline-4:5-dicarboxylic acid, diamide of, and its tetra-acetyl derivative, amide, and methyl ester, 380.
Glycerides, natural mixed, configuration of, 773.
X-ray and thermal examination of, 554.
Glycerol, thalloss derivative, 1381.
Glycine, conductivity and viscosity of, 76.
Glycogen, structure of, 1399.
Glycolic acid, dithallium salt, 1381.
Grignard reagents, action of, on esters of optically-active carboxylic acids, 436.
 on α -nitro-olefins, 1494.
 solutions, experiments with, 847.
Guaiaretic acid, diacetyl derivative, 950.
4-Guanidino-2-benzoyloxypyrimidine, 6-chloro-, and its picrate, 733.
4-Guanidino-2:6-dibenzoyloxypyrimidine, 733.
4-Guanidino-2-hydroxy-1:3-diaza-acridine, and its salts, 734.
4-Guanidino-2:6-dihydroxypyrimidine, 733.
4-Guanidinopyrimidine, 2:6-dichloro-, 733.

H.

Halogens, addition of, to unsaturated compounds, 628, 630, 1168.
 kinetics of substitution by, in aromatic compounds, 1167.
Halogen compounds, positive, homolytic bond fission of, 492.
Heptadecane, 1-amino-, and its acetyl derivative, 199.
 9-amino-, *m*-nitrobenzenesulphonate, 199.
Hepta-3:5-dien-2-one 2:4-dinitrophenylsemicarbazone, 1390.
[2:2:1]bicycloHeptene-2, oxidation of, 818.
O-**Heptyxamine**, and its hydrobromide, 966.
Heptoxy-3:5-dinitrobenzamide, 967.
Heptoxguanidine nitrate, 967.
Heptoxmethane, 966.
 α -n-Heptylacetoacetic acid, ethyl ester, 1039.
O-**Heptylbenzamidoxime**, 968.

α -n-Heptylideneacetoacetic acid, ethyl ester, preparation of, 1038.
1-n-Heptylidene-n-heptaldehyde dinitrophenylhydrazone, 966.
n-Heptylphosphonic acid, diethyl ester, 1466.
Heterocyclic compounds, configuration of, 4.
 synthesis of, Hofmann reaction applied to, 378.
Hexachlorodisiloxane, organic derivatives of, 1590.
Hexadecylethylamine, and its hydrochloride, 190.
Hexamethylenediammonium bistoluene-*p*-sulphonate, 503.
1:6-Hexamethylenedi-*O*-benzamidoxime, 968.
1:6-Hexamethylenedioxydiamine dihydrochloride, 967.
1:6-Hexamethylenedioxydiguanidine dinitrate, 967.
5:5-cycloHexamethylene-2:4-dithiohydantoin, 683.
Hexamethylenetetramine, additive compound of, with 2-nitro-2-ethylpropane-1:3-diol, 925.
cycloHexane, 1-chloro-2-thiocyano-, 1529.
cycloHexane series, alcohols of, 205.
Hexathallium inositol, 1382.
cycloHexene thioepoxide, 1530.
 Δ^4 -cycloHexene methyl ether, 105.
cycloHexenylbutylenoacetic acid, ethyl ester, 773.
cycloHex-1-enyl- α -isobutyric acid, bromo lactone, 1165.
cycloHex-1-enyl- α -isobutyrolactone, 2-hydroxy-, 1166.
1-cycloHexenylpentane-1-carboxylic acid, 773.
Hex-2-en-4-yne-1:6-diol, and its bisphenylurethane, 1589.
Hex-3-en-5-yn-2-ol, and its α -naphthylurethane, 1585.
n-Hexamidine, 5-amino-, 5-benzoyl derivative, hydrochloride, 1377.
N-Hexovanillylamide, derivatives of, 615.
Hexoxyamine hydrobromide and hydrochloride, 966.
Hexoxydiguanide nitrate, 966.
Hexoxyguanidine nitrate, 966.
Hexoxymethane, 966.
cycloHexyl isoamyl sulphide, 40.
cyclohexenyl sulphide, 1529.
phenyl sulphide, 46.
cycloHexylacetic acid, 2-hydroxy-, lactone, and its phenylhydrazide, 1164.
N-cycloHexyl-1-amidino-n-heptane, and its hydrochloride, 1115.
cycloHexyl isoamyl sulphone, 40.
N-cycloHexylanisamidine, and its salts, 1115.
cycloHexyl- α -isobutyric acid, 1:2-dihydroxy-, lactone, 1165.
O-**Hexylecholestanone oxime**, 966.
O-**Hexylecholestanone oxime**, 966.
cycloHexyl-n-decylamine hydrobromide, 201.
N-cycloHexyl- α -diethylacetamidine, and its chloride, 1114.
cycloHexylglycolic sulphone, 39.
cycloHexyl-n-hexylamine hydrochloride, 201.
cycloHexylmethyleneimine, 1118.
cycloHexyl-n-nonylamine hydrochloride, 201.
cycloHexyl-n-octylamine hydrochloride, 201.
1-cycloHexylpentane-1-carboxylic acid, and its *p*-bromophenacyl ester, 772.
1-cycloHexylpent-1-ene-1-carboxylic acid, and its *p*-bromophenacyl ester, 772.
N-cycloHexylphenylacetamidine, and its picrate, 1115.
cycloHexyl phenyl sulphone, 40.
n-Hexylphosphonic acid, diethyl ester, 1466.
 α -cycloHexyl- β -propylacrylic acid from cyclohexanol, 772.
cycloHexylthioglycolic acid, 39.
Hofmann reaction in synthesis of heterocyclic compounds, 378.
Homovanillin, 1692.
2-Homovanillylcyclohexanol, 1696.
2-Homovanillylidene-cyclohexanone, and its 2-*O*-acetyl derivative, 1696.
Hydantoin, and its derivatives, spectra of, absorption, 331.
4-Hydrazino-5:5-dimethyl-2-thiohydantoin, 686.
1-Hydrindenol, and its derivatives, 95.
Hydrocarbons, aromatic, catalysed gas-phase reactions of, 928.
 fluorescence quenching of, van der Waals' complexes in, 130.
 polycyclic, 940.
 metabolism of, 801.
Hydrogen, reduction of oxides by carbon monoxide and, 1239.
Hydrogen sulphide, reaction of, with olefins, infra-red analysis applied to, 1540.
 with olefins, di-isoprenes, and rubber, 1532.
Hydroxymethyldialkylamines, condensation of, with nitro-paraffins, 1511.
Hydoxycholic acid, epimeride of, 812.

I.

Iminazoles, synthesis of, 96.
Indene, derivatives of, 1697.
 recovery of, from heavy naphtha, 369.
Indene, 5-nitro-, synthesis of, 95.
Indoles, formation of, from substituted cinnolines, 1649.
Indole series, synthesis in, 558.
Inositol, hexathallium derivative, 1382.
Iodination, catalytic. See Catalytic iodination.
 of aromatic compounds, 1167.
Iodine, kinetics of reaction of, with copper, in various solvents, 1119.
 solutions, reaction of, with tin, in organic solvents, 736.
Iodine chloride, iodination by, 1167.
Periodates, oxidation of carbohydrazes by, 1427.
 ψ -**Ionone** 2:4-dinitrophenylsemicarbazone, 1390.
Iron thiosulphate, complex, 335.
Iron organic compounds:—
 Ferric thiocyanate, complex, in ethyl-alcoholic solution, 336.
Isotopes, thermodynamics of, 562.

J.

Javanicin, and its derivatives, 1021.

K.

Kaempferide, 124.
*iso*Kaempferide, and its acetyl derivative, 124.
Kaempferol methyl ethers, synthesis of, 122.
3-Keto-2-acetyl-2:3-dihydrobenzthiazine, and its 2:4-dinitrophenylhydrazones, 1621.
3-Keto-2-benzoyl-2:3-dihydrobenzthiazine, 1621.
2-Keto-1-benzoyl-1:2-dihydrobenziso-thiazole S-oxide, 764.
3-Keto-*n*-butyl cyanide 2:4-dinitrophenylhydrazones, 1507.
9-Keto-5-carbethoxy-2-ethylmorphane ethobromide, 400.
2-Keto-3:12-diaza-2:12-dihydroacridine, 4-amino-, and its hydrochloride, 733.
9'-Keto-3':4'-di-*tert*.-butyl-8'-azaphenalino(7':8':2:3)- ψ -indole, 2'(or 5')-bromo-, 746.
 2'(or 5')-nitro-, 745.
2-Keto-1- β -diethylaminoethyl-1- β -carbethoxyisopropyl-1:2:3:4-tetrahydronaphthalene, 400.
4-Keto-6:7-dimethoxy-1-veratryl-1:2:3:4-tetrahydronaphthalene, 851.
1-Keto-6:8-dimethyl-1:2:3:4-tetrahydronaphthalene-5-hydroxy-, 537.
2-Keto-4:4-dimethyl-2:3:5:6-tetrahydro-1:3:4-oxadiazinium chloride, 181.
5-Keto-2-ethoxy-3-acetyl-2-methyltetrahydro-oxazole, 100.
3-Keto-6-(2-furyl)-2:3:4:5-tetrahydropyridazine, 1194.
8-Ketoheptonic acid, methyl ester, and its semicarbazone, 1108.
2-Ketocyclohexylacetic acid, and its 2:4-dinitrophenylhydrazones, 1164.
2-Ketocyclohexyl- α -isobutyric acid, and its 2:4-dinitrophenylhydrazones, 1166.
2-Ketocyclohexylmalonic acid, and its derivatives, 1162.
2-Ketocyclohexyl- α -propionic acid, 2-hydroxy-, and its lactone, 1164.
 β -Keto- β -3-indolylpropionic acid, ethyl ester, 558.
1-Keto-5-methoxy-6:8-dimethyl-1:2:3:4-tetrahydronaphthalene, and 2-bromo-, 537.
1-Keto-5-methoxy-6:8-dimethyl-1:2:3:4-tetrahydronaphthalene-2-carboxylic acid, ethyl ester, 538.
1-Keto-5-methoxy-6:8-dimethyl-1:2:3:4-tetrahydronaphthalene-2-glyoxylic acid, ethyl ester, 538.
1-Keto-5-methoxy-6:8-dimethyl-1:2:3:4-tetrahydronaphthalene-2- α -propionic acid, and its lactone, 539.
12-Keto-9-methoxy-2:3:5:12-tetrahydro- β -quinindene, 635.
3-Keto-2-methyl-*n*-amyl cyanide 2:4-dinitrophenylhydrazones, 1507.
2-Keto-1-methyl-1- β -diethylaminoethyl-1:2:3:4-tetrahydronaphthalene, 401.
5-Keto-2-methyl-4:5-dihydroiminazole-4-carboxylic-1-malonic acid, ethyl ester, 100.
2-Keto-1-methyl-1:2-dihydro-*p*-phenanthroline methiodide, 1661.
9-(8'-Keto-1'-methyl-1':6'-dihydro-3'-pyridyl)phenanthridine, and 3-nitro-, and their derivatives, 1414.

9-Keto-5-methyl-2-ethyl-6:7-benzomorphane ethobromide, 401.
Ketones, reaction of, with nitro-paraffins, 1517.
 reduction of, by primary alcohols in presence of alkalis, 750.
1-Keto-3-(4'-nitro-2'-methoxyphenyl)-2-methyltetrahydrophthalazine-4-acetic acid, and its methyl ester, 464.
1-Keto-3-(2':4'-dinitrophenyl)-2-methyltetrahydrophthalazine-4-acetic acid, 833.
2-Keto-1-phenylacetyl-1:2-dihydrobenziso-thiazole S-oxide, 764.
2-Keto-1-propionyl-1:2-dihydrobenziso-thiazole S-oxide, 763.
12-Keto-2:3:5:12-tetrahydro- β -quinindene, 9-chloro-, 636.
2-Keto-4:4:6-trimethylhexahydropyrimidine, and its dibenzoyl derivative, 1398.
Kinetics, chemical, 694.
 of anionotropic rearrangement, 1096.

 of nickel, rare-earth, and zirconium groups, analysis of, 1347.
Metallic halides, complex, crystal structure of, 1662.
Methacrylic acid, methyl ester, diamagnetic susceptibility and magneto-optic rotation of, and of its polymerides, 1350.
Methane, trinitro-, derivatives, synthesis of, 1234.
Methionine, synthesis of, 1609.
7-Methoxyacridine, 5-amino-2-cyano-, and 5-chloro-2-cyano-, 639.
 5-amino-3-cyano-, and 5-chloro-3-cyano-, 640.
 α -**Methoxyacrylic acid**, 1033.
 β -**Methoxyacrylic acid**, and its 2:4-dinitrophenylhydrazones, 1032.
2-(2'-Methoxyanilino)isocindolinone-3-acetic acid, 2-4'-nitro-, 464.
2-Methoxyanilinoquinoline, 4-chloro-, 905.
4-Methoxyanthranilamide, 894.

- 4-Methoxyanthranilic acid, 894.
preparation of, 1038.
- 5-Methoxyanthranilic acid, preparation of, 894.
- Methoxy-1-asanthraquinones, 544.
- 1'-Methoxy-1:2'-azonaphthalene, 4-nitro-, 78.
- 4'-Methoxy-1:1'-azonaphthalene, 4-nitro-, 78.
- 4-Methoxybenzamide, 2-nitro-, 894.
- 2-Methoxy-1:2-benzanthracene, and its picrate, 940.
- 2-Methoxy-1:2-benzanthraquinone, 942.
- 4-Methoxybenzoic acid, 2-nitro-, preparation of, 1038.
- 2-(2'-Methoxybenzoyl)-1-naphthoic acid, and its acetoxy-lactone, 943.
- β -4-Methoxybenzoylpropionamide, 1195.
- β -3- and -4-Methoxybenzoylpropionic acids, 1194.
- β -3- and -4-Methoxybenzoylpropionitriles, 1193.
- 3-Methoxybenzylacetone, and its semicarbazone, 196.
- 4-Methoxybenzylacetoxime, 196.
- 3-Methoxybutane, 2-amino-, and its derivatives, 1477.
- 2-nitro-, 1476.
- 4-Methoxycinnoline, 6-chloro-, 1655.
- 6-Methoxycinnoline, 4-chloro-, 920.
- 6-Methoxy-1:2:7:8-dibenzocarbazole, 3-amino-, and 3-nitro-, 78.
- ω -Methoxy-2:4-dibenzoylresacetophenone, 1683.
- 2-Methoxydiethyl ether, 2-nitro-, 1476.
- 2-Methoxy-9:10-dihydrophenanthrene, 3-hydroxy-, 3-acetyl derivative, 1696.
- 9-Methoxy-2:3-dihydro- β -quinindene, 12-amino-, and 12-chloro-, 636.
- 12-hydroxy-, 1037.
- 6-Methoxy-2:3-di-*p*-methoxyphenylindene, 1697.
- 2-Methoxy-3:5-dimethylacetophenone, 538.
- 2-Methoxy-9:10-dimethyl-1:2-benzanthracene, 940, 942.
- β -(2-Methoxy-3:5-dimethylbenzoyl)acrylic acid, and α -chloro-, ethyl ester, 538.
- α -(2-Methoxy-3:5-dimethylbenzoyl)butane- $\beta\gamma$ -dicarboxylic acid, 538.
- α -(2-Methoxy-3:5-dimethylbenzoyl)butane- $\beta\gamma$ -tricarboxylic acid, ethyl ester, 538.
- β -(2-Methoxy-3:5-dimethylbenzoyl)propionic acid, 536.
- 4'-Methoxy-4:5-dimethylidiphenylamine, 3-amino-, and its picrate, and 3-nitro-, 914.
- γ -(2-Methoxy-3:5-dimethylphenyl)butyric acid, 537.
- α -(β -2-Methoxy-3:5-dimethylphenylethyl)- α' -methylsuccinic acid, 538.
- 5-Methoxy-6:8-dimethyl-1:2:3:4-tetrahydronaphthalene, 537.
- 4'-Methoxydiphenylamine-2-carboxylic acid, 4-cyano-, 640.
- 5-cyano-, 639.
- 1-Methoxy-4-ethoxy-3-(2':4'-dinitrophenyl)-3:4-dihydrophthalazine, 835.
- 6-Methoxy-3-ethylquinaldine, 4-hydroxy-, 1038.
- Methoxyethyl-1:2:3:4-tetrahydroacridones, 1038.
- 3-Methoxyflaven, 7:2':4'-trihydroxy-, 2':4'-dibenzoyl derivative, 1684.
- 3-Methoxyflavylium chloride, 7:2':4'-trihydroxy-, 2':4'-dibenzoyl derivative, 1684.
- 7-Methoxyflavylium salts, 349.
- 3-Methoxyflavone, 5:7:4'-trihydroxy-. See *iso*Kaempferide.
- 4'-Methoxyflavone, 3:5:7-trihydroxy-. See *Kaempferide*.
- Methoxy-3-*n*-heptylquinaldines, 4-hydroxy-, 1038.
- 2-Methoxy- Δ^4 -cyclohexenone 2:4-dinitrophenylhydrazones, 105.
- 2'-Methoxy-9:10-dihydroxy-9:10-dimethyl-9:10-dihydro-1:2-benzanthracene, 942.
- 5-Methoxy-1:4-dihydroxynaphthalene, 354.
- 6-Methoxy-2-*p*-methoxyphenylindene, 1697.
- 3-Methoxy-2-methyl-*n*-butyl alcohol, 2-nitro-, 1477.
- 4-Methoxymethyl-2-(2-chlorovinyl)-1:3-dithia-2-arsacyclopentane, 595.
- 1-Methoxy-4-methylcyclohexene, 1647.
- 5-Methoxy-2-methyl-6-methoxymethylpyridine, and its picrate, 133.
- 2-Methoxy-4-methylpenta-1:3-diene-1-carboxylic acid, 3-hydroxy-, lactone, 807.
- 2-Methoxy-4-methylpenta-1:4-diene-1-carboxylic acid, 3-hydroxy-, lactone, and its 2:4-dinitrophenylhydrazones, 807.
- 3-Methoxy-6-methylpicolinic acid, 133.
- 2-Methoxymethylpropane-1:3-diol, 2-amino-, pierolonate, and 2-nitro-, 1477.
- 3-Methoxy-6-methylpyridazine, and its hydrochloride, 243.
- 2'-Methoxy-3-methyl-2-stilbazole, and its methiodide, 1699.
- 4'-Methoxy-2-methyl-2-stilbazole, and its methiodide, 1698.
- Methoxymethyl-1:2:3:4-tetrahydroacridones, 1037, 1038.
- 6-Methoxy-2-methyltetrahydroisoquinoline, 193.
- 1-Methoxynaphthalene, 2:4:6-trinitro-5-hydroxy-, 5-acetyl derivative, 353.
- 5-Methoxynaphthalene, 8-amino-1-hydroxy-, 1-acetyl derivative, 354.
- 1-hydroxy-, 1-acetyl derivative, nitration of, 350.
- 6-Methoxynaphthalene, 2-cyano-, 162.
- 5-Methoxy-1:4-naphthaquinone, and its derivatives, 354.
- 6-Methoxy-2-naphthimino-ether dihydrochloride, 162.
- 5-Methoxy-1-naphthol, nitration of, 350.
- 5-Methoxy-1-naphthol, *mono*- and *di*-nitro-derivatives, and their 1-acetyl derivatives, 352.
- 2-(2'-Methoxynaphthoyl-1')-benzoic acid, 942.
- 5-Methoxy-1-naphthylamine, 2,4-dinitro-, and its acetyl derivative, 355.
- 2-Methoxy-1-naphthylmethylen- α - and - β -naphthylamines, 1047.
- 2-Methoxy-1-naphthylmethylenexylidines, 1047.
- o*-Methoxy-*p*-nitrophenylhydrazine, 465.
- 4-Methoxy-3-(2':4'-dinitrophenyl)-4-methyl-3:4-dihydrophthalazine, 1-hydroxy-, 836.
- 2-Methoxyphenanthrene, 3-hydroxy-, and its acetyl derivative, 1697.
- m*-Methoxyphenyl cyanide, preparation of, 161.
- 4-Methoxyphenyl cyanide, 2-nitro-, preparation of, 1038.
- 3-Methoxyphenylalanine, β -4-hydroxy-, preparation of, 1695.
- N*-*p*-Methoxyphenyl-*N'*-*m*-aminophenylguanidine, hydrochloride, 916.
- β -3-Methoxyphenylbutyramide, 196.
- γ -(*p*-Methoxyphenyl)butyric acid, α -amino-, 1572.
- p*-Methoxyphenylcyanamide, 916.
- p*-Methoxyphenyldiallylphosphine, and its mercurichloride, 1448.
- N*-*p*-Methoxyphenyl-*N'*- β -*p*-diethylaminoethylaminophenylguanidine, 916.
- 3-(2'-Methoxyphenyl)-3:4-dihydrophthalazine-4-acetic acid, 1-hydroxy-3:4'-amino-, 1-hydroxy-3:4'-nitro-, and its derivatives, 464.
- 3-(2'-Methoxyphenyl)-3:4-dihydrophthalazine-1-sulphonio-4-acetic acid, 3:4'-nitro-, sodium hydrogen salt, 463.
- p*-Methoxyphenyldi- β -methylallylphosphine, and its mercurichloride, 1449.
- m*-Methoxyphenylethynylcarbinol, 348.
- m*-Methoxyphenylethynyl ketone, 348.
- 3'-Methoxyphenylindole, 3:4'-hydroxy-, and its derivatives, 1695.
- 4-Methoxy-4-phenyl-3-methyl-*n*-butyl cyanide, 3-nitro-, 1507.
- p*-Methoxyphenylmethyl-di- β -methylallylphosphonium iodide, and its salts, 1449.
- 2-Methoxy-3-phenyl-1-methylphthalaz-4-one, 4'-amino-, and its acetyl derivative, 4'-nitro-, 467.
- 2'-Methoxy-3-phenyl-4-methylphthalaz-1-one, 4'-amino-, and its acetyl derivative, 467.
- 4'-nitro-, and its picrate, 466.
- 2'-Methoxy-*N*-phenyl-3-methylphthalimidine, 4'-amino-, and its acetyl derivative, 468.
- γ -(Methoxyphenyl)- α -methyl-*n*-propylamines, salts of, 196.
- 2-*m*-Methoxyphenyl- β -naphthopyrylium salts, 348.
- N*-*p*-Methoxyphenyl-*N'*-*m*-nitrophenylguanidine, and its hydrochloride, 916.
- 2'-Methoxy-3-phenylphthalaz-1-one, 4'-amino-, and its acetyl derivative, 466.
- 4'-nitro-, and its picrate, 464.
- 2'-Methoxy-3-phenylphthalaz-4-one, 4'-amino-, and its acetyl derivative, and 4'-nitro-, 465.
- 2'-Methoxy-*N*-phenylphthalimidine, 4'-amino-, and its acetyl derivative, 466.
- p*-Methoxyphenylpropaldehyde, and its semicarbazone, 1572.
- o*-Methoxyphenylpropionic acid, dimerization of, 224.
- α -(2-Methoxyphenyl)propylamine, picrate, 196.
- 9-*p*-Methoxyphenylxanthene, 1000.
- 3-Methoxyphthalic acid, 6-nitro-, 355.
- 3-Methoxyphthalic anhydride, 6-nitro-, 354.
- 1-Methoxycyclopropane-1-carboxamide, 1034.
- 2-Methoxypropionophenone oxime, 196.
- 3-Methoxy-*n*-propyl alcohol, 2-nitro-, 1476.
- Methoxy-*n*-propylbenzenesulphonic acids, hydroxy-. See *Di*-hydroengenolsulphonic acids.
- 6-Methoxyquinaldine, 4-substituted derivatives, 1552.

- 6-Methoxyquinoline-4-sulphonic acid, 1553.
 7-Methoxyquinazoline, 2:4-dichloro-, and 2:4-dihydroxy-, 899.
 6- and 7-Methoxyquinazolones, 4-chloro-, 895.
 5-Methoxyquinoline, and its salts, 440.
 7-Methoxyquinoline, and its dichromate, 441.
 5-Methoxyquinoline-8-carboxylic acid, 440.
 β -6-Methoxyquinolyl(4)acrylic acid, 1686.
 4-(8-Methoxy-6'-quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine, and its trihydrochloride, 1619.
 2-(Methoxyquinolylamino)-6-methylpyrimidines, 4-chloro-, 1617.
 2-(Methoxyquinolylamino)-4-hydroxy-6-methylpyrimidines, 1617.
 β -6-Methoxyquinolyl(4)ethylamine, synthesis of, and its dihydrochloride, 1684, 1687.
 β -6-Methoxyquinolyl(4)ethylguanidine, synthesis of, and its nitrate, 1684, 1687.
 γ -6-Methoxyquinolyl(4)propane, *aaa*-trichloro- β -hydroxy-, 1686.
 β -6-Methoxyquinolyl(4)propionamide, synthesis of, and its benzoate, 1684, 1687.
 β -6-Methoxyquinolyl(4)propionic acid, and its derivatives, 1686.

p-Methoxystyrylmethylcarbinol, and its α -naphthylurethane, 1096.
 Methoxy-1:2:3:4-tetrahydroacridones, 1036, 1037.
 γ -6-Methoxy-1:2:3:4-tetrahydro-1-naphthylidenecrotonic acid, and its methyl ester, 1364.
 7-Methoxytetralin, 1-amino-, and its hydrochloride, 196.
 7-Methoxy-1-tetralone oxime, 196.
 1-Methoxythioxanthone, 4-amino-, 1234.
 α -(4-Methoxy-*m*-tolyl)ethylamine, picrate, 196.
 Methyl 2-aminoethyl ether, picrate, 1476, 1477.
 2-aminoethyl sulphide, 1479.
 2:4-diamino-2-methylamyl ether, and its bis-2:4-dinitro-phenylurea derivative, 1492.
 2-benzoyloxyethyl sulphide, 769.
 β -benzoylpropimino-ether hydrochloride, 1195.
 2-benzylaminoethyl sulphide, and its salts, 771.
 4-bromonitro-2-nitro-2-methylamyl ether, 1491.
 cyanide, amino-, and its derivatives, 1371.
 ether, reaction of, with benzene, 928.
 2:3-dimercaptopropyl ether, 594.
 nitro-*tert*-.butyl ether, 1476.
 2-nitroethyl ether, 1475.
 2-nitroethyl sulphide, 1479.
 2:4-dinitro-2-methylamyl ether, 1491.
 2:4-dinitro-2-methylamyl sulphide, 1492.

 2-nitro-1-phenyl-*n*-propyl ether, 1476.
 2-nitro-*n*- and -*iso*-propyl ethers, 1476.
 2-nitropropyl sulphide, 1479.
 2-phenoxyethyl sulphide, 770.
 3-Methyl 1:2-acetone 5:6-anhydroglucose, preparation of, 1677.
 2-Methyl acetone *L*-arabinose, and its anilide, 1344.
 3-Methyl 1:2-acetone *L*-arabinose, 1063.
 3-Methyl 1:2-acetone glucosufuranose barium 6-sulphate, 1677.
 2-Methyl 3:4-acetone β -methyl-*L*-arabopyranoside, 1343.
 6-Methyl 3:4-acetone β -methylgalactoside, and its barium 2-sulphate, 1677, 1678.
 4-Methylacetophenone, 3-amino-, 3-acetyl derivative, 3-bromo-, 5-bromo-2-amino-, 2-hydroxy-, and 2-nitro-, 5-chloro-2-amino-, and 2-nitro-, 3-chloro-2-nitro-, 2- and 3-nitro-5-amino-, 2-nitro-3-amino-, and their acetyl derivatives, 229.
 4-Methyl-2-(ω -acetylsulphanilamidodecyl)thiazole, 1377.
 4-Methyl-2-(1-acetylsulphanilamidodecyl)thiazole, 1376.
 4-Methyl-2-(2'-acetylsulphanilamidodecyl)thiazole, 1376.
 4-Methyl-2-acetylsulphanilamidomethylthiazole, 1373.
 4-Methyl-2-(3'-acetylsulphanilamidopropyl)thiazole, 1377.
 10-Methylacridinium halides, chloro- and fluoro-amino-, 762.
 α -Methylaltrioside, 2-bromo-, 16.
 2-chloro-, 14.
 4-Methylamino-2'-*N*-benzenesulphonylcarbamyldiphenyl sulphide, and its nitroso-derivative, 1232.
 2-Methylamino-6-benzoyloxypyrimidine, 4-chloro-, 732.
 4-Methylamino-2-carboxydiphenyl sulphide, and its acetyl derivative, 1232.
 4-Methylamino-2-carboxydiphenyl sulphide-3-sulphonic acid, 1233.
 4-Methyl-2-(ω -aminodecyl)thiazole, 1377.
 2-Methylamino-4:6-dibenzoyloxypyrimidine, 732.
 4-Methylamino-2:6-dibenzoyloxypyrimidine, 732.
 5-Methylamino-3:7-dimethylacridine, 2-amino-, 249.
 Methyl 2-aminoethyl sulphone, 1479.
 4-Methyl-2-(1'-aminoethyl)thiazole, 1375.
 4-Methyl-2-(2'-aminoethyl)thiazole, 1376.
 2-Methylamino-4-hydroxydiazacridine, 734.
 2-Methylamino-4:6-dihydroxypyrimidine, 732.
 4-Methylamino-2:6-dihydroxypyrimidine, 732.
 1-Methylamino-7-hydroxytetralin, *N*-methylurethane, 195.
 1-Methylamino-5-methoxynaphthalene, 2:4:8-trinitro-, 355.
 4-Methyl-2-aminomethylthiazole, 1373.
 4-Methyl-2-aminomethylthiazole-5-carboxylic acid, and its hydrochloride, 1373.
 Methyl 2-aminopropyl sulphone, 1479.
 4-Methyl 2-(3'-aminopropyl)thiazole, 1377.
 2-Methylaminothioxanthone, 1233.
 Methylammonium thiocyanate, 394.
N-Methyl-*N'*-*n*-amylbenzamidinium picrate, 385.
 5-Methyl-5-*n*-amyl-2:4-dithiohydantoin, 683.
 2-*N*-Methylanilino-4:6-dihydroxypyrimidine, 1247.
 2-(Methylanilino)*iso*indolinone-3-acetic acid, 2-(2':4'-dinitro)-methyl ester, 833.
 6-*N*-Methylanilino-8-methylthio-2-methylpurine, hydrochloride, 947.
N-Methylanilinophosphonic acid, dibenzyl ester, 677.
 4-*N*-Methylanilinopyrimidine, 2:6- and 4:6-dichloro-, 1247.
 2-Methylanilinoquinoline, 4-chloro-, 905.
 3-Methyl-2-anilinoethylidenebenzthiazoline, 6-nitro-, 957.
 1-Methyl-2-anilinoethylidenedihydroquinoline, 958.
 3-Methyl-2-anilinoethylidenethiazolidine, 959.
 2-Methyl *D*-arabinose, and its derivatives, 1343.
 2-Methyl *L*-arabinose phenylhydrazone, 1344.
 3-Methyl *L*-arabinose, 1062.
 3-Methyl *L*-arabofuranolactone, 1063.
 3-Methyl *L*-arabonamide, 1064.
 3-Methyl *L*-arabonanilide, 1063.
 2-Methylisarsindoline, 5-chloro-, and its derivatives, 669.
 Methylation, biological, 424.
N-Methylbenzamidinium benzenesulphonate, 385.
 4-Methyl-2-(ω -benzamidodecyl)thiazole, 1377.
 4-Methyl-2-(1'-benzamidodecyl)thiazole, 1375.
 4-Methyl-2-(2'-benzamidodecyl)thiazole, 1376.
 4-Methyl-2-benzamidomethylthiazole, 1373.
 4-Methyl-2-benzamidomethylthiazole-5-carboxylic acid, and its ethyl ester, 1373.
 6-Methyl-1:2-benzanthracene, 10-hydroxy-, 10-acetyl derivative, 765.

 3-nitro-2:4-dihydroxy-, 2:4-diacetyl derivative, 1473.
*neo*Pentane, nitro-, 1498.
cycloPentane-cis-1:3-dicarboxylic acid, preparation of, 818.
cycloPentane-2-carboxylic acid, ethyl ester, condensation products of, with aromatic amines, 1420.
*iso*Pentamethiol, reactions of, with olefins, 36.
Pent-2-en-4-yn-1-ol, preparation of, 1583.
 reactions of, 1586.
Pent-3-en-1-yn-5-ol-1-carboxylic acid, and its *S*-benzylisothiuronium salt, 1588.

Periodates. See under Iodine.

***β*-Phellandrene tetrabromide**, 1039.

2-Phenacylbenzothiazole, 1621.

1-Phenacyl-2-(2-hydroxypropyl)pyridinium chloroplatinate, 672.

1-Phenacyl- α -phenylethyldimethylammonium bromide, rearrangement of, 93.

Phenanthraquinone, reactions of, in sunlight, 997.

Phenanthraquinoneimine, reaction of, with diazomethane, 651.

Phenanthrene, 8:10-dihydroxy-, cuminyldihydroxymethylene, 2:4-dimethoxyphenylhydroxymethylene, and 2-methoxy-1-naphthylhydroxymethylene ethers, 1000.

Phenanthridine, chemistry of, 1410.

Phenanthridines, 84.

Phenanthridine series, 67.

***p*-Phenanthroline**, derivatives of, 1659.

2-Phenanthroline, 2-chloro-, and 2-hydroxy-, 1660. 2:7-dichloro-, 1661.

Phenanthrozole, formation of, from reaction of diazomethane with phenanthraquinoneimine, 651.

2-*p*-Phenetidinocyclopent-1-enecarboxylic acid, ethyl ester, 1037.

Phenol, iodination of, acid catalysis of, 342.

Phenols, and their ethers, *m*-nitration of, 1416.

reactions of, with alkylisofornanilides, 976. spectra of, infra-red, 644. vibrational, and of their derivatives and resins, 1260.

Phenoxstibines, preparation of, 4.

4-Phenoxycinnoline, 6:7- and 7:8-dichloro-, 232.

3-(2-Phenoxyethyl)hexane-1-carboxylic acid, 224.

5-Phenoxy-7-methoxyacridine, 2-cyano-, 639.

12-Phenoxy-9-methoxy-2:3-dihydro- β -quinindene, 636.

2-Phenoxy-4-methyl-1:8-naphthyridine, 7-amino-, and its acetyl derivative, 1409.

***p*-Phenoxyphenyldiallylphosphine**, and its mercurichloride, 1448.

7-Phenoxy-4-phenyl-2-methyl-1:8-naphthyridine, 1410.

5-Phenoxyprimidine, 2-amino-4-hydroxy-, 4-chloro-2-amino-, and their acetyl derivatives, 45, 46.

5-Phenoxytetrahydroacridine, 636.

Phenyl 2-amino-4-methyl-5-thiazyl sulphide, *p*-chloro-, and *p*-nitro-, 115.

2-amino-5-thiazyl sulphide, *p*-chloro-, and its 2-acetyl derivative, 113.

p-nitro-, 112, 117.

dihydromyrcene sulphide, 40.

cyclohexyl sulphide, *p*-chloro-, 1551.

2-methylthioethyl sulphide and its mercurichloride, 772.

2-nitroethyl sulphide, 2:4-dinitro-, 1480.

2-nitroisopropyl sulphide, 1479.

octyl sulphide, and *p*-amino-, and *p*-nitro-, 53.

Phenylacetamidic picrate, 392.

Phenylacetic acid, 3:5-diiodo-, 3:4:5-triiodo-, 3:5-diiodo-4-amino-, and 3:5-diiodo-2-hydroxy-, 203.

Phenylacetic acids, iodo-, preparation of, 202.

2-Phenyl-2-*p*-acetoxypheyl-1:2:3:4-tetrahydroisophospholinium bromide, 1641.

γ -Phenylallyldimethylamine, and its salts, 168.

***N*-Phenyl-*p*-amidinophenyl methyl sulphone**, 394.

Phenyl 2-amino-4-methyl-5-thiazyl sulphone, *p*-amino-, *p*-chloro-, and *p*-nitro-, and their acetyl derivatives, 117.

Phenyl 2-amino-4-phenyl-5-thiazyl sulphone, *p*-nitro-, and its acetyl derivative, 118.

Phenyl 2-amino-5-thiazyl sulphone, *p*-chloro-, and its 2-acetyl derivative, 114.

3-Phenyl-4-*p*-anisyleinnoline *N*-oxide, 1651.

Phenyl-*p*-anisyl-2-(*o*-methoxymethylphenyl)ethylphosphine, and its methiodide, 1641.

2-Phenylisarsindoline, preparation of, and its derivatives, 665.

2-Phenylisarsindoline, 2-*p*-chloro-, and its derivatives, 666. 5-chloro-, and its derivatives, 668.

***N*-Phenylbenzamidine**, *o*-nitro-, and its picrate, 1114.

1-Phenylbenzotriazole, 5:4'-dichloro-, 938.

1-Phenylbenzothiazolone, *N*-*p*-nitro-, 1234.

Phenylbenzylbis-3-benzoyloxypropylarsonium chloroplatinate, 624.

4-Phenyl-3-benzyleinnoline *N*-oxide, 1651.

Phenyl-2-benzoyloxyethylarsine acid, and its derivatives, 624.

Phenylbis-2-aminoethylarsine, and *p*-amino-, and *p*-chloro-, and their derivatives, 622.

Phenylbis-2-carboxyethylarsine, and *p*-chloro-, 623.

Phenylbis-2-carboxy-*n*-propylarsine, and its derivatives, 623.

Phenylbis-2-cyanoethylarsine, 621.

Phenylbis-2-cyanoethylarsine, *p*-amino-, and *p*-chloro-, and their derivatives, 621.

α -Phenyl- $\beta\beta'$ -bis-(*p*-dimethylaminophenyl)acrylonitrile, 643.

Phenyl-*p*-bromophenylchloroarsine, 511.

Phenyl- γ -bromophenyl-2-(*o*-methoxymethylphenyl)ethylphosphine, and its methiodide, 1640.

2-Phenyl-2-*p*-bromophenyl-1:2:3:4-tetrahydroisophospholinium salts, 1640.

1-Phenylbutadienes, preparation and ultra-violet absorption of, 1087.

1-Phenylbuta-1:3-diene, 1-*p*-bromo-, -chloro-, and -fluoro-, and their adducts, 1095.

3-Phenylbutane, 2-amino-, 1499.

γ -Phenylbutyric acid, α -amino- γ -*p*-hydroxy-, synthesis of, 1571.

***N*-Phenylcarbamic acid**, 2-*o*-methoxymethylphenylethyl ester, 1640.

5-Phenylcarbamidodecane, 1496.

4-Phenylcarbamido-3:3-dimethylhexane, 1497.

- 2':3'-isoPropylidene adenosine-5' dibenzyl phosphate,** 650.
- 2-isoPropylideneamino-4-methoxybenzamide,** 894.
- 3:4-isoPropylidene β-methyl-L-arabopyranoside,** 971.
- n-Propyl-n-octylcarbinol,** 758.
- 4-isoPropylphenol, 3-amino-, and 3-nitro-,** 186.
- p-isoPropylphenylidialylphosphine, and its mercurichloride,** 1448.
- p-isoPropylphenylid-β-methylallylphosphine, and its mercurichloride,** 1449.
- 4-Propylpiperidine-2-carboxylic acid, ethyl ester,** 224.
- Propylthiol, 2-nitro-,** 1481.
- Purines, 8-amino-, synthesis of,** 943.
- Purine nucleosides, synthesis of,** 355.
- spiroPyran, thermochromic, action of Grignard solutions on,** 847.
- Pyrazine, derivatives of,** 370, 373, 1179, 1183.
- N-oxides, conversion of, into chloropyrazines,** 1183.
- Pyrazine-, 2-hydroxy-,** 372.
- Pyrene, crystal structure of,** 358.
- Pyridazine, derivatives, formation of, from sucrose,** 239, 549.
- Pyridine, chemistry of,** 132.
- reaction of, with p-acetamidobenzenesulphonyl azide,** 60.
- with thiocyanates,** 816.
- Pyridine, 2-amino-, toluene-p-sulphonate, and its benzoyl derivative, benzenesulphonate,** 387.
- 3-hydroxy-, methiodide, and its N-phenylurethane, and its methiodide,** 188, 190.
- 2-hydroxy-5-cyano-,** 88.
- Pyridinium salts, N-amino-,** 65.
- 3:4:2':3'-Pyridosacridine, derivatives of,** 678.
- 3:4:2':3'-Pyridosacridine, 2:5-dichloro-, and 2:5:8-trichloro-,** 680.
- 3:4:2':3'-Pyridosacridone, 2-chloro-,** 680.
- 4-α-Pyridylamino-6-methoxyquinaldine,** 1553.
- N-2-Pyridylbenzamidine, and its salts,** 1115.
- 2-Pyridyldihydroglyoxalines, and their salts,** 500.
- N-2-Pyridyl-N'-methylbenzamidine, and its picrate,** 388.
- N-2-Pyridyl-p-methylsulphonylbenzamidine, and its picrate,** 1115.
- 9-(3'-Pyridyl)phenanthridine, and its derivatives,** 1413.
- 9-(3'-Pyridyl)phenanthridine, amino- and nitro-derivatives, and their derivatives,** 1414, 1415.
- 2-α-Pyridyl-3:4:5:6-tetrahydropyrimidine picrate,** 500.
- 2-2'-Pyridylthionaphthen, 3-hydroxy-,** 1577.
- Pyrimidine, 2-ω-amino- and 2-ω-sulphanilamido-alkyl derivatives of,** 1372.
- Pyrimidine, trichloro-, preparation of, from barbituric acid, by-product from,** 1247.
- 4-chloro-2:6-diamino-,** 46.
- Pyrimidines, formation of,** 1394.
- quinolylamino-substituted,** 1613.
- Pyrococlines, chemistry of,** 670, 672.
- Pyrococline-2-carboxylic acid, synthesis of, and its methyl ester,** 672.
- Pyrrrole dyes, conversion of β-cyclopropionitriles into,** 1190.
- 4-(2'-Pyrryl)thiazole, 2-amino-,** 1659.
- 4-(2'-Pyrryl)-2-methylthiazole,** 1659.
- Pyruvic acid, and its ethyl ester, 1-chloro-2-naphthylhydrazones,** 543.

Q.

- 2-(6'-Quinaldylamino)-4-hydroxy-6-methylpyrimidine,** 1616.
- 2-(6'-Quinaldylamino)-6-methylpyrimidine, 4-chloro-,** 1616.
- Quinasolines, 4-substituted,** 896.
- Quinasolone, 4:7-dichloro- and 4-chloro-7-nitro-,** 895.
- Quindoline, preparation of, and its derivatives,** 607.
- Quindoline, 7- and 11-amino-, 7-bromo-, 11-cyano-, 7- and 11-nitro-, and 7:4-dinitro-, and their derivatives,** 609, 610, 611.
- Quindoline-11-carboxylic acid, and its derivatives, and 7-amino-, 7-bromo-, and 7-nitro-,** 609, 611.
- Quinol, additive complexes of, structure of,** 208.
- Quinolines, 5-bromo-, 5-chloro-, 5-cyano-, and 5-hydroxy-, and their derivatives,** 440.
- 7-bromo-, 7-chloro-, 7-cyano-, and 7-hydroxy-, and their salts,** 441.
- 7-chloro-, and its salts,** 443.
- 7-chloro-2:4-dihydroxy-,** 906.
- 8-hydroxy-, N-methylurethane methiodide,** 190.
- 5- and 7-nitro-, and their derivatives,** 442.

2-Quinolylamino-4-dialkylaminoalkylamino-6-methylpyrimidines, 1617, 1618.
4-(6'- and 8'-Quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidines, and their hydrochlorides, 1617.
4-(8'-Quinolylamino)-2- β -diethylaminoethylamino-6-methylpyrimidine, and its dihydrochloride, 1619.
2-(5'- and 8'-Quinolylamino)-4-hydroxy-6-methylpyrimidines, 1616.
2-(5'- and 8'-Quinolylamino)-6-methylpyrimidines, 4-chloro-, 1617.
2-(6'-Quinolylamino)-4-hydroxy-6-methylpyrimidine, 1616.
2-(6'-Quinolylamino)-6-methylpyrimidine, 4-chloro-, 1616.
4-Quinolylanthranilic acid, 8'-chloro-, and its ethyl ester, 679.
4:8-dichloro, 680.
2-2'-Quinolylthionaphthen, 3-hydroxy-, and its acetyl derivative, 1577.

R.

R.63, constitution of, 1331.
Reactions, aromatic side-chain, in relation to polar effects of substituents, 713.
Reduction by dissolving metals, 102, 1642.
Resins, natural, phenolic, 948.
 phenolic, spectra of, vibrational, 1260.
Respiration, stimulants of, 307.
Retenequinone, reaction of, with stilbene, 999.
Rhamnocitrin, constitution of, 122.
Rhamnose, determination of, 1048.
d-Ribobenziminazole, preparation of, 23, 24.
Ricinoleic acid, alkaline scission of, 753.
Ricinoleovanillylamide, 614.
Rings, alicyclic, formation of, cyclisation in, 1028.
Rubber, reaction of, with hydrogen sulphide, 1532.
 with sulphur, 1699.
 vulcanised, infra-red spectrum of, 1699.
Rubrene, fluorescence of, in various solvents, 106.

S.

Saccharic acid, thallium hydrogen salt, 1381.
Sandmeyer reaction, 173.
 ψ -Santonin, constitution of, 533, 1157.
Sarcosine, ethyl ester and nitrile of, 661.
Schizophyllum commune, sulphide conversion by, 424.
Scopulariopsis brevicaulis, sulphide conversion by, 424.
Selenium dioxide, dehydrogenation and oxidation with, 764.
Silica gel, preparation of, 33.
Silicochloroform, organic derivatives of, 1592.
Silicon organic compounds :—
 silicon tetrachloride, derivatives of, 1592.
Skraup reaction with *m*-substituted anilines, 437.
Sodium, reduction by, in liquid ammonia, 102.
Sodium organic compounds :—
 sodium acetylde, reaction of, with epichlorohydrin, 1583.
 butoxide, reduction of $\alpha\beta$ -unsaturated carbonyl compounds by, 851.
Solids, granular, heat exchange between gas streams and, 416.
Solubility at high temperatures, apparatus for measuring, 1679.
Solutes, separation of, chromatographic, 1308, 1321.
Solvents, fluorescence quenching in, 105.
 non-aqueous, acid-base catalysis in, 24.
Spectra, absorption, infra-red, of amides, 1248.
 of 2:4-dinitrophenylsemicarbazones, 1387.
 of nitrogen organic compounds, 331.
 ultra-violet, 1104.
 of 1-phenylbutadienes, phenylpropenylcarbinols, and styrylmethylcarbinols, 1087.
 infra-red, measurement of, and their value in structural diagnosis, 978.
 of alkylphenols, 644.
 of macromolecules, 289.
 of olefins, 1540.
 vibrational, of phenolic derivatives and resins, 1260.
Squalene, reaction of, with sulphur, 1546.
Stearamide, and its isethionate, 741.
Stilbene, addition of halogens to, 628.
 reaction of, with retenequinone, 999.

5 T

Stilbene, *trans*-*pp'*-diamino-, 1454.
Strawberry pectic acid, molecular structure of, 1218.
Strontium azide, crystal structure of, 881.
Strychnine, 78, 1554, 1557.
*neo*Strychnine, preparation of, and its *N*-oxide benzoate, 78.
Strychnineacetic acid, degradation of, 1557.
Styrene, addition of halogens to, 628.
Styrene, β -bromo- β -nitro-, β -chloro- β -nitro-, and β -nitro-, physical properties of, 1105.
Styrylmethylcarbinol α -naphthylurethane, 1096.
Styrylmethylcarbinol, *p*-bromo-, *p*-chloro-, and *p*-fluoro-, and their α -naphthylurethanes, 1095.
Styrylmethylcarbinols, substituted, preparation and ultra-violet adsorption of, 1087.
2-Styrylpyridine, 2-*p*-cyano-, 88.
4-Styrylpyridine, 4-*p*-amino-, 560.
Substitution, aromatic, by halogens, 1167.
 at saturated carbon atoms, 558.
 by halogen, methoxy, and methyl groups attached to phenyl, 1096.
Sucrose, conversion of, into furan compounds, 396.
 into pyridazine derivatives, 239, 549.
 into thiazole derivatives, 590, 1400.
1:4:3:6-dianhydro mannitol and **1:4:3:6-dianhydro sorbitol** from, 433.
 solubility of, in water at high temperatures, 1678.
 thallous derivative, 1382.
Sugars, methylated, quantitative separation of, 1344.
2-(4'-Sulphamidobenzyl)dihydroglyoxaline, salts, 501.
Sulphanil-O-acetylvanillylamide, sulphate, 616.
5-Sulphanilamido-2-benzylthiazole, and its 5-acetyl derivative, 1597.
3-Sulphanilamido-6-methylpyridazine, and its derivatives, 243.
2-Sulphanilamido-4-methylthiazole-5-acetic acid, and its derivatives, 591, 592.
Sulphanilamidothiazoles from levulinic acid, 590.
Sulphanilhomovanillylamide, and its hydrochloride and *N*⁴-acetyl derivative, 616.
Sulphanilic acid, conductivity and viscosity of, 76.
Sulphanil- α -vanillylethylamide, and its hydrochloride and *N*⁴-acetyl derivative, 616.
 β -Sulphanilyl- α -acetylguanidine, 822.
 β -Sulphanilyl- α -2-diethylaminoethylguanidine, and its acetyl derivative, 822.
 β -Sulphanilyl- α -2-diethylguanidine, and its acetyl derivative, 821.
 β -Sulphanilyl- α -dimethylguanidine, and its acetyl derivative, 821.
Sulphanilylguanidine, derivatives of, 820.
 β -Sulphanilyl- α -2-methoxyethylguanidine, and its acetyl derivative, 821.
 β -Sulphanilyl- α -methylguanidine, 821.
Sulphanilylvanill-N⁷-phenylamine, and its *N*⁴:*O*-diacetyl derivative, 617.
*poly*Sulphides, organic, thermal decomposition of, 1547.
Sulphide linkings, fission of, by moulds, 424.
2-(4'-Sulphonamidophenyl)dihydroglyoxaline, 500.
Sulphones, unsaturated, reaction of, with nitro-paraffins, 1514.
1-4'-Sulphophenyl-2:7-diazacycloheptene, 500.
2-(4'-Sulphophenyl)dihydroglyoxaline, 500.
2-(4'-Sulphophenyl)-3:4:5:6-tetrahydropyrimidine, 500.
Sulphur, reaction of, and of its compounds, with olefinic substances, 1519, 1532, 1546, 1547.
 with rubber, 1699.
 with squalene, 1546.
Sulphuric acid, nitration in, 474, 1185.
Sulphur organic compounds, 693.
Sulphuric acid. See under Sulphur.
Sunlight, photochemical reactions in, 997.
Surface chemistry, applications of, in colloid science, 1422.
Sylvan, production of, from furfuraldehyde, 1068.
Systems, azeotropic, binary, pressure and temperature relationships in, 597.

 Tri-(2-isothiocarbamido-2-ethyl)amine tetrahydrochloride, 322.
 Trypanocides, 67.
 l-Tubocurarine chloride, 937.

U.

Undecanal 2:4-dinitrophenylhydrazones, 199.
 Unsaturated compounds, kinetics of halogen addition to, 628, 630, 1168.
 Ureas, substituted, from ω -alkylenediamines, 307.
 Ureido-. See Carbamido-.
 Uridine phosphates, 338.
 Uridylic acid, diubucine salt, 341.

V.

Valeric acid, *l*-erythro-1:3:4-trihydroxy-, phenylhydrazide, 972.
 Valeroidine, structure of, 1330.
 Vanillin, amides and amines from, 613.
 Vanillinanil, O-acetyl and O-benzoyl derivatives of, 616.
 Vanill-N'-phenylamine, O-acetyl and O-benzoyl derivatives, 616, 617.
 Vapour pressure of liquids, relation of, to density and viscosity, 822.
 Vinyl compounds, polymerisation of, in gas and liquid phase, 274.
 2-Vinyl-1:3-dithia-2-arsacyclohexane, 2-2-chloro-, 595.
 5-hydroxy-2-2-chloro-, 595.
 2-Vinyl-1:3-dithia-2-arsacyclopentane, 2-2-chloro-, 595.
 1-Vinylcyclohexene, 1-1-nitro-, and its dimer, 1474.
 Vinylphosphonic acid, diethyl ester, 1467.
 Viscosity of aqueous solutions of amino-acids, 74.
 of liquids, relation of, to density and vapour pressure, 822.
 Volume, molecular, of lanthanon elements and their derivatives, 1084.

X.

m-Xylene, ω -bromo-5-nitro-, $\omega\omega'$ -dibromo-5-nitro-, and $\omega\omega'$ -diido-5-nitro-, 1236.
 3-(*o*-3-Xylidino)-4:5-benzocoumaran, 1047.
 3-(*m*-4-Xylidino)-4:5-benzocoumaran, 1047.
 3-(*p*-Xylidino)-4:5-benzocoumaran, 1047.
 3-(*p*-Xylidino)-4:5-coumaran, hydrochloride, 1047.
 1-(*l*-Xylopyranosidoglyoxaline-4:5-dicarboxamide, and its triacetyl derivative, 381.
 9-(*l*-Xylopyranosidoxanthine, 381.
l-Xylosidoglyoxaline-4:5-dicarboxylic acid, 1-triacetyl derivative, methyl ester, 380.
p-Xylyldiallylphosphine, and its mercurichloride, 1448.
p-Xylyldi- β -methylallylphosphine, and its mercurichloride, 1449.
o-Xylylene bis(phenyldimethylarsonium picrate), 665.
o-Xylylene, 4-chloro-, derivatives of, 668.
o-Xylylenearsinic acid, and its nitrate, 667.
p-Xylylmethyl-di- β -methylallylphosphonium iodide, and its salts, 1449.

Y.

Yeast ribonucleic acid, constitution of, 21, 338.
 Yttrium in rare-earth group, 118.
 relation of, to lanthanons, 1084.

FORMULA INDEX.

THE following index of organic compounds of known empirical formula is arranged according to Richter's system (see *Lexikon der Kohlenstoff-Verbindungen*).

The elements are given in the order, C, H, O, N, Cl, Br, I, F, S, P, and the remainder alphabetically.

The compounds are arranged—

Firstly, in groups according to the number of carbon atoms (thus C₁ group, C₂ group, etc.).

Secondly, according to the number of other elements besides carbon contained in the molecule (thus 5 IV indicates that the molecule contains five carbon atoms and four other elements).

Thirdly, according to the nature of the elements present in the molecule (given in the above order).

Fourthly, according to the number of atoms of each single element (except carbon) present in the molecule.

Salts are placed with the compounds from which they are derived. The chlorides, bromides, iodides, and cyanides of quaternary ammonium bases, however, are registered as group-substances.

C₁ Group.

CCl₄Se Perchloromethylselenol, 1083.

1 III

CH₄N₂S Thiourea, reaction of, with *s*-dichloroacetone, 323.

CH₃Cl₂Si Methylchlorosilane, 1593.

C₂ Group.

C₂H₂O₂ Oxalic acid, dihydrate, crystal and molecular structure of, 142; hydrated rare-earth salts of, 1687.

C₂H₄O₂ Glycollic acid, dithallium salt, 1381.

C₂H₆O Dimethyl ether, reaction of, with benzene, 928.

C₂H₆N₂ 2-Aminoethylamine, toluene-*p*-sulphonate, 502.

Ethylenediamine, bistoluene-*p*-sulphonate, 503.

C₂Cl₄Se Hexachlorodimethyl selenide, 1083.

2 III

C₂H₄Cl₂Sn Ethyltrichlorotin, 1450.

C₂H₅N₂S Methylammonium thiocyanate, 394.

C₂H₅Cl₂Si Ethyldichlorosilane, 1593.

2 IV

C₂HOCl₂S Trichlorothiolacetic acid, 141.

C₂H₂OCl₂S Dichlorothiolacetic acid, 140.

C₂H₄OCl₂Si₂ Ethylpentachlorodisiloxane, 1591.

C₂H₄O₂NS 2-Nitroethylthiol, 1480.

C₂H₄O₂NS 2-Nitroethanesulphonic acid, salts, 1483.

C₂H₄OCl₂Si₂ Dimethyltetrachlorodisiloxane, 1592.

C₃ Group.

C₃H₄O₂ Lactic acid, dithallium salt, 1381.

C₃H₆N₂ 1-Aminoethyl cyanide, hydrochloride, 1371.

Sarcosine nitrile, and its picrate, 661.

C₃H₁₀N₂ Trimethylenediamine, bistoluene-*p*-sulphonate, 503.

3 III

C₃H₃ON Oxazole, 102.

C₃H₄OCl₂ *s*-Dichloroacetone, reaction of, with thiourea, 323.

C₃H₄N₂S 2-Aminothiazole, chlorination of, with sulphuryl chloride, 431.

C₃H₈O₂TL Trithallium glycerol, 1381.

C₃H₆O₂S Methyl vinyl sulphone, 1515.

C₃H₈O₂TL Dithallium trimethylene glycol, 1382.

C₃H₇O₂N 1-Nitropropane, reaction of, with formaldehyde and ammonia, 924.

C₃H₇O₂N Methyl 2-nitroethyl ether, 1475.

C₃H₇Br₂Sn Allylpentabromostannic acid, 1450.

C₃H₈OS₂ 2:3-Dimercaptopropanol, 594.

C₃H₇O₂N₂ 2-Nitroisopropylamine, hydrochloride, 1488.

C₃H₇ON Methyl 2-aminoethyl ether, picrate, 1476, 1477.

C₃H₈NS₂ 2:3-Dimercaptopropylamine, 594.

3 IV

C₃H₄ON₂S 2-Thiohydantoin, 580.

C₃H₇O₂NS Methyl 2-nitroethyl sulphide, 1479.

2-Nitropropylthiol, 1481.

C₃H₇O₂NS Methyl 2-nitroethyl sulphone, 1479.

C₃H₇O₂NS 1- and 2-Nitropropane-2-sulphonic acids, salts, 1483.

C₃H₇ON₂Cl α -Amidinoacetamide, hydrochloride, 617.

C₃H₇O₂NS Methyl 2-aminoethyl sulphone, 1479.

C₄ Group.

C₈H₁₈, *iso*Butylene, dimerisation of, 250.

4 II

- C₆H₈O₄, Acetylenedicarboxylic acid, dihydrate, crystal and molecular structure of, 148.
 C₆H₈O₄, *meso*Tartaric acid, tetrathallium salt, 1380.
 C₆H₈O₄, Vinyl acetate, vapour, polymerisation of, 1201, 1211.
 C₆H₈O₄, α -Methoxyacrylic acid, 1033.
 β -Methoxyacrylic acid, 1032.
 C₆H₈N₂, 3-Amino-*n*-propyl cyanide, and its hydrochloride, 1370.
 C₆H₁₀N₂, *NN'*-Dimethylacetamidine, salts, 385.
 C₆H₁₂N₂, Tetramethylenediamine, bistoluene-*p*-sulphonate, 503.

4 III

- C₆H₈O₂N Oxazole-4-carboxylic acid, 102.
 C₆H₈ON 2-Methyloxazole, and its picrate, 101.
 C₆H₈O₂N₂, 2-Nitropropyl cyanides, 1501.
 C₆H₈O₂TI₄, Tetrathallium erythritol, 1381.
 C₆H₈N₂S₂, 2-Amino-4-mercaptomethylthiazole, 324.
 5-Amino-2-mercapto-4-methylthiazole, hydrochloride, 1607.
 C₆H₈O₂N 2-Nitrobut-2-ene, 1477.
 C₆H₈Cl₂S₂, 2,2'-Dichlorodiethyl sulphide, thermal decomposition of, 318.
 C₆H₈O₂N 2-Acetoxyethylamine, and its hydrochloride, 530.
 C₆H₈O₂N Methyl 2-nitropropyl ethers, 1476.
 Nitro-*tert.*-butyl alcohol, 1518.
 C₆H₈O₂N 2-Nitro-3-methoxy-*n*-propyl alcohol, 1476.
 C₆H₁₀ON₂, β -Amino*iso*butyramide, picrate, 1502.
 C₆H₁₀OS₂, Methyl 2:3-dimercaptopropyl ether, 594.
 C₆H₁₀O₂N₂, 2-Nitro-3-aminobutane, hydrochloride, 1488.
 1-Nitro-2-amino-2-methylpropane, hydrochloride, 1488.
 C₆H₁₁ON Butoxyamine, hydrobromide, 968.
 Methyl-2-methoxyethylamine, and its picrolonate, 313.
 C₆H₁₁NS₂, 2:2'-Dimercaptodiethylamine, and its hydrochloride, 322.
 C₆H₁₁ClSi Diethylchlorosilane, 1593.
 C₆OCl₄Si₂ Bispentachloroethyltetrachlorodisiloxane, 1592.

4 IV

- C₆H₈ClSAs 2-(2-Chlorovinyl)-1:3-dithia-2-arsacyclopentane, 595.
 C₆H₈O₂NS 2-Nitroethyl thiolacetate, 1480.
 C₆H₈O₂NS Carboxymethyl 2-nitroethyl sulphide, 1480.
 C₆H₈O₂NS Carboxymethyl 2-nitroethyl sulphone, 1480.
 C₆H₈O₂NCl 3-Chloropropyl carbamate, 179.
 C₆H₈O₂N₂S Di-(2-nitroethyl) sulphide, 1480.
 C₆H₈O₂N₂S Di-(2-nitroethyl) sulphone, 1480.
 C₆H₈OSAs 2-Methyl-4-hydroxymethyl-1:3-dithia-2-arsacyclopentane, 595.
 C₆H₈O₂NS Carboxymethyl 2-aminoethyl sulphide, 1480.
 Methyl 2-nitropropyl sulphide, 1479.
 Nitro-*tert.*-butylthiol, 1480.
 C₆H₈O₂NS Methyl 2-nitropropyl sulphone, 1479.
 C₆H₈O₂NS 2-Nitrobutane-3-sulphonic acid, salts, 1484.
 1-Nitro-2-methylpropane-2-sulphonic acid, sodium salt, 1483.
 C₆H₁₀ONCl Formimido*iso*propyl ethyl hydrochloride, 101.
 C₆H₁₀OClSi₂ Diethyltetrachlorodisiloxane, 1591.
 C₆H₁₀O₂NCl 2-Chloroethyl *N*-dimethylcarbamate, 179.
 C₆H₁₁O₂NS 2-Aminobutane-3-sulphonic acid, 1484.
 1-Amino-2-methylpropane-2-sulphonic acid, 1484.

C₅ Group.

- C₈H₁₀O₂, But-1-en-3-yne-1-carboxylic acid, and its *S*-benzylisothiuronium salt, 1589.
 Furfuraldehyde, hydrogenation of, 1068.
 C₈H₈N₂, 2-Aminopyridine, toluene-*p*-sulphonate, 387.
 N-Aminopyridine, salts, 65.
 C₈H₈N₂, 3-Amino-6-methylpyridazine, and its salts, 243.
 C₈H₁₀O₄, 3-Deoxy-*L*-xylose, 972.
 C₈H₁₀N₂, Amino-*tert.*-butyl cyanide, and its salts, 1502.
 2-Amino-1-methyl-*n*-propyl cyanide, hydrochloride, 1502.
 C₈H₁₁N Piperidine, benzenesulphonate, 385.
 C₈H₁₁N, 1:3-Diamino-2:2-dimethylpropane, 1502.

5 III

- C₈H₈O₂N₂, 5-Nitroso-4:6-dihydroxy-2-isonitrosomethylpyrimidine, and its sodium salt, 947.
 C₈H₈N₂Cl₂, 4:6-Dichloro-5-methylpyrimidine, 50.
 C₈H₈ON 3-Hydroxypyridine, methiodide, 188.
 C₈H₈ON, 5:6-(4:5-Triazolo)-4-hydroxy-2-methylpyrimidine, and its sodium hydrogen salt, 947.
 C₈H₈O₂N 2-Methyloxazole-4-carboxylic acid, 101.
 C₈H₈N₂Cl 3-Chloro-6-methylpyridazine, and its salts, 242.
 C₈H₈N₂Cl₂, 2:6-Dichloro-4-guanidinopyrimidine, 733.
 C₈H₈ON, 6-Methyl-3-pyridazone, and its salts, 241, 242.
 1747

- $C_4H_6O_2N_2$ 4:6-Dihydroxy-5-methylpyrimidine, 49.
 $C_4H_5N_2Cl$ 4-Chloro-2-amino-5-methylpyrimidine, 45.
 4-Chloro-6-amino-5-methylpyrimidine, 50.
 $C_4H_5O_2N$ 2-Nitro-3-methylbuta-1:3-diene, 1474.
 3-Nitropenta-1:3-diene, 1473.
 $C_4H_6O_2N_2$ 2-Methylamino-4:6-dihydroxypyrimidine, 732.
 4-Methylamino-2:6-dihydroxypyrimidine, 732.

 $C_4H_{11}O_2N$ 2-Nitropentane, 1499.
 Nitro-neopentane, 1498.
 $C_4H_{11}O_2N$ Methyl nitro-*tert.*-butyl ether, 1476.
 2-Nitro-3-methoxybutane, 1476.
 1- and 3-Nitro-2-methylbutan-2-ols, 1519.
 Propyl 2-nitroethyl ethers, 1476.
 $C_4H_{11}O_2N$ 2-Nitro-2'-methoxydiethyl ether, 1476.
 $C_4H_{11}O_2N$ 2-Nitro-2-methoxymethylpropane-1:3-diol, 1477.
 $C_4H_{11}NCl_2$ Methyl-di-(2-chloroethyl)amine, and its salts, 516.
 $C_4H_{11}ON_2$ β -Amino- $\alpha\alpha$ -dimethylpropionamide, and its salts, 1502.
 β -Amino- α -methylbutyramide, picrolonate, 1502.
 $C_4H_{12}O_2N_2$ 2-Nitro-2-hydroxymethylbutylamine, and its hydrochloride, 928.
 $C_4H_{12}ON_2$ 2-Amino-3-methoxybutane, and its platinichloride, 1477.
 3-Amino-2-methylbutan-2-ol, 1519.
 Ethyl-2-methoxyethylamine, and its picrolonate, 313.
 2-*iso*Propoxyethylamine, and its picrolonate, 313.
 $C_4H_{13}O_2N$ Methyl-di-(2-hydroxyethyl)amine, and its di-*p*-nitrobenzoate, 516.
 Methyl-2-(2-hydroxyethoxy)ethylamine, and its salts, 532.
 $C_4H_{13}O_2N$ 2-Amino-2-methoxymethylpropane-1:3-diol, picrolonate, 1477.
 $C_4H_{13}O_2P$ Diethyl methylphosphonate, 1466.
 $C_4H_{13}NCl_2$ β -Chloroethylisopropylamine hydrochloride, 59.
 Dimethyl- β -chloropropylamine hydrochloride, 59.
 $C_4H_{13}NS_2$ Methyl-2:2'-dimercaptodiethylamine, and its salts, 321.
 $C_4H_{13}IS_2$ Dimethyl-2-methylthioethylsulphonium iodide, 770.
 $C_4H_{13}ON_2$ 5-Amino-2-methylpyrrolidine *N*-oxide, 1511.
 $C_4H_{13}O_2N_2$ 4-Amino-*N*- β -diethylaminoethylphenol *N*-methylurethane, salts, 190.

5 IV

- $C_5H_8N_2ClBr$ 4-Chloro-5-bromo-2-amino-6-methylpyrimidine, 46.
 $C_5H_7O_2ClS$ α -Chloro- β -(acetylthio)propionic acid, 1033.
 $C_5H_7O_2BrS$ α -Bromo- β -(acetylthio)propionic acid, 1033.
 C_5H_7ONBr α -Bromo- $\beta\beta$ -dimethylacrylamide, 1033.
 C_5H_7ONCl Morpholine-*N*-carboxychloride, 313.
 $C_5H_8ClS_2As$ 2-(2-Chlorovinyl)-1:3-dithia-2-arsacyclohexane, 595.
 4-Methyl-2-(2-chlorovinyl)-1:3-dithia-2-arsacyclopentane, 595.
 $C_5H_{10}O_2NCl$ 4-Chlorobutyl carbamate, 179.
 $C_5H_{11}O_2NS$ Methyl 2-nitro-1-methylpropyl sulphide, 1479.
 $C_5H_{11}O_2N_2Cl$ 2-Keto-4:4-dimethyl-2:3:5:6-tetrahydro-1:3:4-oxadiazinium chloride, 181.
 $C_5H_{11}ONCl$ Methyl-2-chloroethyl-2-hydroxyethylamine, and its salts, 519.
 $C_5H_{13}O_2N_2Cl$ 2-Dimethylaminoethanol hydrochloride urethane, 181.

5 V

- $C_5H_7OCIS_2As$ 5-Hydroxy-2-(2-chlorovinyl)-1:3-dithia-2-arsacyclohexane, 595.
 4-Hydroxymethyl-2-(2-chlorovinyl)-1:3-dithia-2-arsacyclopentane, 595.
 $C_5H_{14}O_2NClS$ Methyl 2-dimethylaminoethanesulphonate hydrochloride, 181.

 C_6 Group.

- C_6H_6 Benzene, reaction of, with methyl ether, 928.

6 II

- $C_6H_8O_4$ Diacetylenedicarboxylic acid, dihydrate, crystal structure of, 1145.
 $C_6H_8O_4$ Methylbut-1-en-3-yne-1-carboxylate, 1589.

- $C_5H_8O_5$ Pent-3-en-1-yn-5-ol-1-carboxylic acid, and its *S*-benzylisothiuronium salt, 1588.
 $C_6H_{10}O_5$ Hex-2-en-4-yne-1:6-diol, 1589.
 $C_6H_{10}O_4$ 2:3-Anhydro- α -methyl-*L*-ribose, 972.
 $C_6H_{10}O_4$ 2:3-Anhydro- β -methyl-*L*-ribose, 971.
 $C_6H_{10}O_4$ 1:4:3:6-Dianhydro-*L*-iditol, hemihydrate, 1404.
 $C_6H_{10}O_5$ 3-Methyl 1-arabofuranolactone, 1063.
 $C_6H_{10}O_5$ Mucic acid, thallous salt, 1381.
 $C_6H_{10}O_5$ Saccharic acid, thallium hydrogen salt, 1381.
 $C_6H_{10}N_4$ 2:5-Diamino-4:6-dimethylpyrimidine, 51.
 $C_6H_{10}S$ *cyclo*Hexene thioepoxide, 1530.
 $C_6H_{12}O_4$ 3-Deoxy- β -methyl-*L*-xylopyranoside, 971.
 $C_6H_{12}O_5$ 2-Methyl *D*-arabinose, 1343.
 $C_6H_{12}O_5$ 3-Methyl arabinose, 1063.
 $C_6H_{12}N_2$ 5-Aminoamyl cyanide, 1370.
 $C_6H_{12}N_2$ 5-Imino-2:2-dimethylpyrrolidine, and its picrate, 1510.
 $C_6H_{12}S$ Propyl allyl sulphide, 1529.
 $C_6H_{12}N$ 2:2-Dimethylpyrrolidine, and its picrate, 1510.
 $C_6H_{12}N$ 2-Amino-3-methylpentane, 1497.
 $C_6H_{12}N_2$ 2:4-Diamino-2-methylpentane, 1398.
 $C_6H_{12}N_2$ Hexamethylenediamine, bistoluene-*p*-sulphonate, 503.

6 III

- $C_6H_7ON_2$ 2-Hydroxy-5-cyanopyridine, 88.
 $C_6H_7O_2N_2$ *p*-Dinitrobenzene, crystal structure of, 884.

 $C_{11}H_{11}N_2Cl$, 4-Chloro-2- γ -dimethylaminopropylamino-5:6-dimethylpyrimidine, 48.

- $C_{11}H_{20}ON_4$ 4- β -Diethylaminoethylamino-2-hydroxy-6-methylpyrimidine, and its salts, 786.
 4- β -Diethylaminoethylamino-6-hydroxy-2-methylpyrimidine, hydrochloride, 1356.
 $C_{11}H_{20}O_2N_4$ 2- γ -Dimethylaminopropylamino-4-hydroxy-5:6-dimethylpyrimidine, 48.
 $C_{11}H_{20}O_2N_4$ 2- γ -Diethylaminopropylamino-4:6-dihydroxypyrimidine, and its salts, 730.
 $C_{11}H_{20}O_2N_4$ 4- γ -Diethylaminopropylamino-2:6-dihydroxypyrimidine, and its salts, 731.
 $C_{11}H_{20}O_2Cl_2$ 10-Chlorodecyl chloroformate, 178.
 $C_{11}H_{20}O_2S_2$ 6-Methyl 3:4-acetone β -methylgalactoside 2-sulphate, barium salt, 1678.
 $C_{11}H_{20}NB_2$ 10-Bromodecyl cyanide, 1370.
 $C_{11}H_{20}N_2Cl$ 4-Chloro-2-amino-6- β -diethylaminoethylamino-5-methylpyrimidine, 47.
 $C_{11}H_{20}N_2Br$ 5-Bromo-2-amino-4- β -diethylaminoethylamino-6-methylpyrimidine, 46.
 $C_{11}H_{21}O_2N$ Ethyl 4-propylpiperidine-2-carboxylate, 224.
 $C_{11}H_{21}O_2N_2$ 5:7-Dinitro-3-hydroxymethyl-5:7-diethyl-1-oxa-3-azacyclooctane, and its hydrochloride, 926.
 $C_{11}H_{21}O_2N_2$ 5-Nitro-5-ethyl-3-(2-nitro-2-hydroxymethylbutyl)tetrahydro-1:3-oxazine, 926.
 $C_{11}H_{21}S$ Dihydromyrcene sulphide methiodide, 1528, 1531.
 $C_{11}H_{21}O_2S$ cycloHexyl isomethyl sulphone, 40.
 $C_{11}H_{21}S_2$ 2:2:6:6-Tetramethyltetrahydrothiopyran methiodide, 1108.
 $C_{11}H_{21}ON$ Triethyl-2-ethylaminoethylurea, 315.
 $C_{11}H_{21}O_2P$ Diethyl *n*-heptylphosphonate, 1466.

11 IV

- $C_{11}H_{10}O_2N_2Cl$ 4-Chloro-2-(*p*-nitrophenyl)-6-methyl-3-pyridazine, 553.
 $C_{11}H_{10}O_2NS$ 4-*o*-Carboxyphenyl-2-methylthiazole, 1657.
 $C_{11}H_{10}O_2NS$ 4-Phenyl-2-methylthiazole-5-carboxylic acid, 1657.
 $C_{11}H_{10}O_2N_2Cl$ 5-*p*-Chlorobenzeneazo-4:6-dihydroxy-2-methylpyrimidine, 947.
 $C_{11}H_{10}ON_2S$ 5-Acetamido-4-phenylthiazole, 1598.
 $C_{11}H_{10}ON_2S_2$ 5-Acetamido-2-mercapto-4-phenylthiazole, 1603.
 $C_{11}H_{10}ON_2Cl$ 2-Chloro-7-acetamido-4-methyl-1:8-naphthyridine, 1409.
 $C_{11}H_{10}O_2N_2S$ 5-Amino-4-carboxy-2-benzylthiazole, 1596.
 $C_{11}H_{10}O_2N_2S$ 4-*p*-Aminophenylsulphonylpyridine *N*-oxide, 54.
 $C_{11}H_{10}O_2N_2S$ 3-*p*-Nitrobenzenesulphonamido-6-methylpyridazine, 243.
 $C_{11}H_{10}ON_2Cl$ 4-Chloro-2-amino-6-*p*-anisidinopyrimidine, and its hydrochloride, 1362.
 $C_{11}H_{10}O_2NS$ *N*-Acetyl derivative of 2-methyldihydro-1:3-benzthiazine-4-one, 764.
 $C_{11}H_{10}O_2N_2S$ *N*-(*p*-Aminobenzenesulphonimido)pyridine, 65.
 $C_{11}H_{10}O_2N_2S_2$ 2-*p*-Nitrobenzenesulphenamido-4:5-dimethylthiazole, 114.
 $C_{11}H_{10}O_2NS$ 6-Methoxyquinoline-4-sulphonic acid, 1553.
 $C_{11}H_{10}ONCl$ 2-(4-Chloro-2-acetamidophenyl)propylene, 810.
 $C_{11}H_{10}O_2N_2S_2$ *p*-Tolyl 2-amino-4-methyl-5-thiazyl sulphone, 117.
 $C_{11}H_{10}O_2N_2S$ 3-Sulphanilamido-6-methylpyridazine, and its dihydrochloride, 243.
 $C_{11}H_{10}O_2N_2S$ β -Acetylthiopropaldehyde dinitrophenylhydrazine, 1610.
 $C_{11}H_{10}N_2Cl$ 6-Chloro-4-methylcinoline ethiodide, 811.
 $C_{11}H_{10}O_2N_2S_2$ 4-Methyl-2-sulphanilamidomethylthiazole, 1373.
 $C_{11}H_{10}ONBr$ 4-Bromo- β -dimethylaminopropiophenone, hydrochloride, 1193.
 $C_{11}H_{10}O_2NCl$ 5-Chloro-2-acetamidophenyldimethylcarbinol, 810.
 $C_{11}H_{10}O_2N_2S$ 2-(4'-Methylsulphonylphenyl)-3:4:5:6-tetrahydropyrimidine, and its toluene-*p*-sulphonate, 500.
 $C_{11}H_{10}O_2N_2S$ 1-(4'-Sulphophenyl)-2:7-diazacycloheptene, 500.
 $C_{11}H_{10}O_2N_2S$ β -Ethylthiopropaldehyde dinitrophenylhydrazine, 1611.
 $C_{11}H_{10}O_2IS$ Dimethyl-2-benzoyloxyethylsulphonium iodide, 769.
 $C_{11}H_{10}O_2NS$ Methyl 2-benzamidopropyl sulphone, 1479.
 $C_{11}H_{10}O_2N_2S_2$ α -Acetylsulphanilamidothiopropionamide, 1375.
 $C_{11}H_{10}O_2N_2S$ β -*p*-Acetamidobenzenesulphonyl- $\alpha\alpha$ -dimethylguanidine, 821.
 $C_{11}H_{10}O_2N_2S$ 5-Nitroso-6-amino-4-*d*-mannosidamino-2-methylthiopyrimidine, 356.
 $C_{11}H_{10}NIS$ Dimethyl-2-benzylaminoethylsulphonium iodide, 771.
 $C_{11}H_{10}ON_2S$ 4:2'-Hydroxyethylimino-5:5-(3'-methyleyclopentamethylene)-2-thiohydantoin, 686.
 $C_{11}H_{10}ON_2Cl$ 6-Chloro-4- γ -diethylaminopropylamino-2-hydroxypyrimidine, and its salts, 731.
 $C_{11}H_{10}O_2N_2S$ 3-Nitro-5-*n*-butylsulphonyl-3-methyl-*n*-amyl cyanide, 1507.
 $C_{11}H_{10}O_2NCl$ 10-Chlorodecyl carbamate, 179.
 $C_{11}H_{10}O_2N_2I$ Trimethyl-2-hydroxyethylammonium iodide piperidylcarbamate, 180.

11 V

- $C_{11}H_{10}O_2N_2ClS$ *p*-Chlorophenyl 2-acetamido-5-thiazyl sulphone, 114.
 $C_{11}H_{10}ONIS$ Dimethyl-2-benzamidomethylsulphonium iodide, 771.

 C_{12} Group.

- $C_{12}H_8$ Acenaphthylene, photochemical decomposition of, 109.

12 II

- $C_{12}H_{10}O_4$ 2-Benzofuryl β -carboxyethyl ketone, 1194.
 Benzyl aconate, 1178.
 Dimethyl octa-1:7-dien-3:5-diyne-1:8-dicarboxylate, 1589.
 $C_{12}H_{10}Cl_2$ Bischloromethylnaphthalenes, 1433.
 $C_{12}H_{11}N_2$ *N*-2-Pyridylbenzamidine, and its salts, 1115.
 $C_{12}H_{11}N_2$ 12-Amino-2:3-dihydro- β -quinidene, and its hydrochloride, 635.
 $C_{12}H_{11}N$ 1-Ethyl-2-methylene-1:2-dihydroquinoline, 956.
 1-Ethyl-4-methylene-1:4-dihydroquinoline, 956.

- $C_{12}H_{16}N_2$ 2-Amino-5-benzeneazo-4:6-dimethylpyrimidine, 51.
 $C_{12}H_{14}O_2$ Dodeca-3:9-dien-5:7-diyne-2:11-diol, 1582.
 $C_{12}H_{14}O_2$ Clavatol acetate, 612.
 $C_{12}H_{16}O_2$ *cyclo*Hexyl coumalate, 1179.
 $C_{12}H_{14}O_2$ Octa-3:5-diyne-1:8-diol diacetate, 1582.
 $C_{12}H_{14}O_2$ *O*-Carbethoxyhomovanillin, 1694.
 $C_{12}H_{14}O_2$ *O*-Carbethoxyhomovanillic acid, 1694.
 $C_{12}H_{14}Cl_2$ 5:8-Bischloromethyl-1:2:3:4-tetrahydronaphthalene, 1434.
 $C_{12}H_{14}N_2$ 2:3-Dimethyl-5-ethylindole, 1633.
 $C_{12}H_{16}P$ Phenyldiallylphosphine, 1448.
 $C_{12}H_{16}As$ Phenyldiallylarsine, 1450.
 $C_{12}H_{16}O_2$ γ -(2-Hydroxy-3:5-dimethylphenyl)butyric acid, 537.
 $C_{12}H_{16}N_2$ 1-Benzyl-2:7-diazacycloheptene, and its picrate, 500.
 NN -Pentamethylenebenzamidine, and its picrate, 392, 394.
 $C_{12}H_{16}S$ *cyclo*Hexyl phenyl sulphide, 40.
 $C_{12}H_{16}N_2$ 2:3-Dimethyl-6-ethylindoline, 1633.
 $C_{12}H_{17}N_2$ 7-Amidino-9-*p*-aminophenylphenanthridine, trihydrochloride, 86.
 $C_{12}H_{18}O_2$ *m-n*-Amyloxyanisole, 104.
 $C_{12}H_{18}O_4$ 2:5-Diallyl 1:4-3:6-dianhydromannitol, 1407.
 $C_{12}H_{18}O_4$ Diallyl dianhydrosorbitol, 1407.
 $C_{12}H_{18}N_2$ *N*-Methyl-*NN'*-diethylbenzamidine, salts, 385.
 $C_{12}H_{18}N_2$ *N*-Methyl-*N'N'*-diethylbenzamidine, salts, 385.
 $C_{12}H_{18}S$ 3:3'-Dicyclohexenyl sulphide, 1529.
 $C_{12}H_{20}O_2$ 1-*cyclo*Hexenylpentane-1-carboxylic acid, 773.
 $C_{12}H_{20}O_2$ 1-*cyclo*Hexylpent-1-ene-1-carboxylic acid, 772.
 $C_{12}H_{20}O_2$ 3:4-Acetone 2-methyl α -methyl-*n*-galacturonoside methyl ester, 1340.
 $C_{12}H_{20}N_2$ 2-Amino-6-dimethylamino-4-isopropyltoluene, 187.
 $C_{12}H_{20}N_2$ 2:5-Di-*sec*-butylpyrazine, and its chloroplatinate, 375.
 $C_{12}H_{20}S$ *cyclo*Hexyl *cyclo*hexenyl sulphide, 1529.
 $C_{12}H_{21}N_2$ 2-Amino-3:6-di-*sec*-butylpyrazine, and its salts, 376.
 $N\beta$ -Diethylaminoethylphenylenediamines, 916.
 $C_{12}H_{21}P$ Tri- β -methylallylphosphine, 1449.
 $C_{12}H_{21}As$ Tri- β -methylallylarsine, 1450.
 $C_{12}H_{22}O_2$ 1-*cyclo*Hexylpentane-1-carboxylic acid, 772.
 $C_{12}H_{22}O_2$ *l*-Menthoxycetic acid, silver salt, 511.
 $C_{12}H_{22}O_{11}$ Sucrose, conversion of, into pyridazine derivatives, 239; conversion of, into thiazole derivatives, 590; solubility of, at high temperatures, 1678.
 $C_{12}H_{22}S_4$ Dicyclohexyl tetrasulphide, 1549.
 $C_{12}H_{22}S_6$ Dicyclohexyl hexasulphide, 1550.
 $C_{12}H_{23}N_2$ 2-Amino-5- β -diethylaminoethylamino-4:6-dimethylpyrimidine, and its dipicrate, 51.
 $C_{12}H_{23}N_2$ 4-Amino-2- β -diethylaminoethylamino-5:6-dimethylpyrimidine, 48.
 $C_{12}H_{23}N_2$ 5-Amino-2- β -diethylaminoethylamino-4:6-dimethylpyrimidine, and its dipicrate, 51.
 $C_{12}H_{23}N_2$ 5-Amino-4- β -diethylaminoethylamino-2:6-dimethylpyrimidine, 50.
 $C_{12}H_{23}N_2$ 2-Amino-4- γ -diethylaminopropylamino-5-methylpyrimidine, 45.
 $C_{12}H_{24}O$ 6-Ethyldec-6-en-5-ol, 758.
 $C_{12}H_{24}N_2$ *N-cyclo*Hexyl- $\alpha\alpha$ -diethylacetamidine, hydrochloride, 1114.
 $C_{12}H_{24}N_2$ 2:6-Diamino-4- γ -diethylaminopropylamino-5-methylpyrimidine, and its bis-3:5-dinitrobenzoate, 47.
 $C_{12}H_{24}S$ Methyl*cyclo*hexyl *iso*amyl sulphide, 40.
 $C_{12}H_{24}N$ *cyclo*Hexyl-*n*-hexylamine, hydrochloride, 201.
 $C_{12}H_{24}N_2$ 2:4:4:6-Tetramethyl-2-(2-amino*isobutyl*)-2:3:4:5-tetrahydropyrimidine, 1398.
 $C_{12}H_{26}O$ *n*-Propyl-*n*-octylcarbinol, 758.
 $C_{12}H_{26}O_2$ Dodecane-2:11-diol, 1582.
 $C_{12}H_{26}O_2$ Dodecane-4:9-diol, 1582.
 $C_{12}H_{27}N$ Di-*n*-hexylamine, *m*-nitrobenzenesulphonate, 199.
 $C_{12}H_{27}N_2$ 2:4:4:6-Tetramethyl-2-(2-amino*isobutyl*)hexahydropyrimidine, 1399.
 $C_{12}H_{27}N_2$ 2-Amino-1:3-bis(diethylamino)-2-methylpropane, 1513.

12 III

- $C_{12}H_8N_2Cl_2$ 2:7-Dichloro-*p*-phenanthroline, 1661.
 $C_{12}H_8O_2N_2$ 2:4:6-Trinitro-5-acetoxy-1-naphthol, 353.
 $C_{12}H_8N_2Cl_2$ 2-Chloro-*p*-phenanthroline, 1660.
 $C_{12}H_8N_2Cl_2$ 5:4'-Dichloro-1-phenylbenzotriazole, 938.
 $C_{12}H_8ON$ 2-Hydroxy-*p*-phenanthroline, 1660.
 $C_{12}H_8ON$ *p*-Phenanthroline *N*-oxide, 1661.
 $C_{12}H_8O_2N_2$ 5:5'-Dicyano- $\alpha\beta$ -2:2'-difurylthane, 398.
 $C_{12}H_8O_2N_2$ 5:5'-Dicyanodifurfuryl ether, 397.
 $C_{12}H_8O_2N_2$ 2:4-Dinitro-5-acetoxy-1-naphthol, 353.
 $C_{12}H_8O_2N_4$ 2:4:6:8-Tetranitro-1:5-dimethoxynaphthalene, 352.
 $C_{12}H_8Cl_2S_4$ Di-*p*-chlorophenyl tetrasulphide, 1549.
 $C_{12}H_8ON$ 2-Cyano-6-methoxynaphthalene, 162.
 $C_{12}H_8O_2N$ 2-Benzofuryl β -cyanoethyl ketone, 1194.
 $C_{12}H_8O_2N$ 6-Nitro-2-naphthyl acetate, 331.
 $C_{12}H_8O_2N$ 7-Nitro-2-naphthyl acetate, 331.
 $C_{12}H_8O_2N_2$ 2:4:6-Trinitro-1:5-dimethoxynaphthalene, 353.

29 V

- $C_{29}H_{26}O_2ClBrS$ 5-Chloro-3-methyl-2'(or 5')-bromo-3':4'-di-*tert*.-butyl-1:7'-thionaphthenacenaphthenylindigo, 746.

C₃₀ Group.

- $C_{30}N_{46}$ Lanostatrienes, 1470.
 $C_{30}H_{50}$ α - and β -Lanostadienes, 1470.
 Squalene, reaction of sulphur with, 1546.

30 II

- $C_{30}H_{16}N_4$ Tetrakis-*p*-cyanophenylethylenc, 83.
 $C_{30}H_{21}Sb$ Tri- β -naphthylstibine, 1570.
 $C_{30}H_{28}O_2$ 7-Hydroxy-2':4'-dibenzoyloxy-3-methoxyflaven, 1684.
 $C_{30}H_{22}N_6$ 1:5-Naphthalenebisazo- β -naphthylamine, 81.
 $C_{30}H_{30}O$ Lanosterol, 1467.

30 III

- $C_{30}H_{20}O_2N_4$ 1:5-Naphthalenebisazo- β -naphthol, 81.
 $C_{30}H_{21}O_7Cl$ 7-Hydroxy-2':4'-dibenzoyloxy-3-methoxyflavylium chloride, 1684.
 $C_{30}H_{20}O_2N_2$ Benzylideneneobrucine, 80.
 $C_{30}H_{32}ON_2$ 2-Amino-3:4-di-*tert*.-butylacenaphthazo- β -naphthol, 744.

30 IV

- $C_{30}H_{27}O_4NS$ 3-Ethyl-2-(3':5'-di-*m*-methoxybenzoylpenta-2':4'-dienylidene)benzthiazoline, 1631.
 $C_{30}H_{24}O_6N_2S$ *NN'*-Dibenzoyl-1:2-bistoluene-*p*-sulphonamidoethane, 504.

C₃₁ Group.

- $C_{31}H_{23}O_2$ 2-(2':3'-Dihydro- β -naphthofuran-2')-2-phenyl- β -naphthopyran, 848.
 $C_{31}H_{24}O_4$ 2:2-Di-*p*-anisyl-3-methylphenanthro-9':10'-1:4-dioxen, 999.

31 IV

- $C_{31}H_{21}ClIA_3$ Phenyl-*m*-tolyl-*p*-phenyl-*p*-chlorophenylarsonium iodide, 510.
 Phenyl-*p*-tolyl-*p*-phenyl-*p*-chlorophenylarsonium iodide, 510.

31 V

- $C_{31}H_{27}O_4N_2IS_2$ Bis-2-(5:6-dimethoxy-3-ethylbenzthiazole)- $\beta\beta'$ -dimethylheptamethincyanine iodide, 962.
 1789

C₃₂ Group.

- C₃₂H₂₄N₂** Bis-2-(3:5-diphenylpyrrole)azamethin, 1200.
C₃₂H₂₄O₂ 2-(2':3'-Dihydro- β -naphthofuran-2')-2-*p*-tolyl- β -naphthopyran, 848.
C₃₂H₂₆O₂ 5:6-Diphenyl-(1'-methyl-7'-isopropylphenanthro)-9':10'-1:4-dioxen, 999.
C₃₂H₄₄O Di-(5-ethyltetradec-4-en-6-yl) ether, 758.

32 III

- C₃₂H₃₀O₂N₄** Bisquindolinoyl, 610.
C₃₂H₃₂O₂N₂ Dimethylaminoethyl hydrogen benzilate, 60.

32 IV

- C₃₂H₂₇ClAs** Phenyl-*p*-ethylphenyl-*p*-phenyl-*p*-chlorophenylarsonium iodide, 510.
C₃₂H₂₇N₃Cl₂S₂ [Bis-2-(3-ethylbenzthiazole)][$\alpha\beta'$ -dimethin-2'-(3'-ethylbenzthiazole)]trimethincyanine di-chloride, 1441.
C₃₂H₂₇N₃I₂S₂ [Bis-2-(3-ethylbenzthiazole)][$\alpha\beta'$ -dimethin-2'-(3'-ethylbenzthiazole)]trimethincyanine di-iodide, 1441.
C₃₂H₂₇N₃I₂Se₂ [Bis-2-(3-ethylbenzselenazole)][$\alpha\beta'$ -dimethin-2'-(3'-ethylbenzselenazole)]trimethincyanine di-iodide, 1442.

32 V

- C₃₂H₂₅N₃Cl₂I₂S₂** [Bis-2-(5-chloro-3-ethylbenzthiazole)][$\alpha\beta'$ -dimethin-2'-(5'-chloro-3'-ethylbenzthiazole)]tri-methincyanine di-iodide, 1442.
C₃₂H₂₅N₃Cl₂As₂Pd Dichlorobis(diphenyl-2-cyano-*n*-propylarsine)palladium, 622.

C₃₃ Group.

- C₃₃H₄₇ON** *O*-Hexylcholestenone oxime, 966.
C₃₃H₄₉ON *O*-Hexylcholestanone oxime, 966.

C₃₄ Group.

- C₃₄H₂₈O₂** Substance, from phenanthraquinone and 9-benzylidenexanthen, 998.
C₃₄H₂₈O₂ 2-(2':3'-Dihydro- β -naphthofuran-2')-2-phenyl-2':3-trimethylene- β -naphthopyran, 848.

34 III

- C₃₄H₂₀O₂N₂** Dodeca-5:7-diyne-4:9-diol bis- α -naphthylurethane, 1582.
C₃₄H₂₂O₂S Substance, from phenanthraquinone and 9-benzylidenethioxanthen, 998.
C₃₄H₂₆O₂N₂ Phthalobis-[γ -(6-methoxy-8-quinolylamino)propyl]amide, and its hydrochloride, 1334.
C₃₄H₄₁O₁₃N Substance, from 4:6-benzylidene 2:3-anhydro α -methylmannoside and ammonia, 20.

34 IV

- C₃₄H₂₀O₂N₂S₂** 1:2'-Bis-(3-keto-2-2'-quinolylthionaphthen), 1577.

C₃₅ Group.

- C₃₅H₂₄O₂** 2-(2':3'-Dihydro- β -naphthofuran-2')-2- α -naphthyl- β -naphthopyran, 848.

35 IV

- C₃₅H₃₃N₇I₂S₂** Bis-2-(3-ethyl-6:7-benzbenzthiazole)- $\beta\beta'$ -dimethylheptamethincyanine iodide, 962.

C₃₆ Group.

- C₃₆H₂₇O₂Sb** Tri-*p*-phenoxyphenylstibine, 1569.

36 IV

- C₃₆H₂₇O₂Cl₂Sb** Tri-*p*-phenoxyphenylstibine dichloride, 1570.
C₃₆H₂₇O₂Br₂Sb Tri-*p*-phenoxyphenylstibine dibromide, 1570.
C₃₆H₂₇O₂I₂Sb Tri-*p*-phenoxyphenylstibine di-iodide, 1570.
C₃₆H₃₀O₂N₂Sb₂ Bis(triphenylstibine)oxide dinitrate, 667.
C₃₆H₂₄O₂N₂As₂ *o*-Xylylene bis(phenyldimethylarsonium picrate), 665.

36 V

- C₃₆H₃₃O₁₄N₆ClAs₂** 4-Chloro-*o*-xylylene bis(phenyldimethyl arsonium picrate), 668.

C₃₇ Group.

- C₃₇H₃₁O₂Cl** *O*-5:2':4'-Tribenzoyl-*O*-3-methylmorinidin chloride, 1684.

C₃₈ Group.

- C₃₈H₂₈O₂** 2-(2':3'-Dihydro- β -naphthofuran-2')-2- α -naphthyl-2':3-trimethylene- β -naphthopyran, 848.

38 III

- C₃₈H₄₀O₂N₄** Tetraphenylethylenetetra-*p*-iminoethyl ether, 84.
C₃₈H₄₂O₂N₂ Substance, from diphenylketen dimer and piperidine, 176.

38 IV

- $C_{30}H_{14}O_2N_4Cl_2$ *l*-Tubocurarine chloride, 937.
 $C_{38}H_{12}O_{10}N_8S_4$ Tetrakis-*p*-amidinophenylethylene tetraisethionate, 84.

 C_{39} Group.

- $C_{39}H_{72}O_5$ $\alpha\alpha'$ -Dielaidin, 558.

 C_{40} Group.

- $C_{40}H_{20}O_2$ 2:2-Dixenylphenanthro-9':10'-1:4-dioxen, 999.
 $C_{40}H_{20}O_4$ 9-*m*-Tolylxanthyl peroxide, 1000.
 $C_{40}H_{16}O$ Mutachrome, pro-vitamin-*A* activity of, 131.

40 IV

- $C_{40}H_{14}O_2N_4Br_2$ 1:1'-Dibromo-3:3'-dinaphthyl-2:2'-bisazo- β -naphthol, 1392.
 $C_{40}H_{18}O_2N_2I_2$ 1-*O*-Methyltubocurarine iodide, 937.

 C_{41} Group.

- $C_{41}H_{30}O_2$ 2:2-Dixenyl-3-methylphenanthro-9':10'-1:4-dioxen, 999.

 C_{42} Group.

- $C_{42}H_{14}O_3As_2$ Bisphenyl-*p*-tolyl-*p*-ethylphenylarsine oxide-dihydroxide, 509.

 C_{44} Group

- $C_{44}H_{37}N_3I_2S_3$ [Bis-2-(3-ethyl-6:7-benzbenzthiazole)][$\alpha\beta'$ -dimethin-2'-(3'-ethyl-6:7'-benzbenzthiazole)]trimethincyanine di-iodide, 1441.

 C_{45} Group.

- $C_{45}H_{12}O_5$ 2-Methyl 3:5-ditrityl methylxylofuranoside, 850.

 C_{46} Group.

- $C_{46}H_{12}O_6$ 2-Acetyl 3:5-ditrityl methylxylofuranoside, 850.

46 III

- $C_{46}H_{30}O_2S_2$ 9- α -Naphthylthioxanthyl peroxide, 1000.

 C_{52} Group.

- $C_{52}H_{32}O_4Cl_2As_2Pd$ Dichlorobis(phenylbis-3-benzyloxypropylarsine)palladium, 624.

 C_{66} Group.

- $C_{66}H_{16}O_4Cl_6As_2Pt$ Phenylbenzylbis-3-benzyloxypropylarsonium chloroplatinate, 624.

SYMBOLS FOR THERMODYNAMICAL AND PHYSICO-CHEMICAL QUANTITIES AND CONVENTIONS RELATING TO THEIR USE, ADOPTED AS RECOMMENDED PRACTICE BY THE CHEMICAL SOCIETY.

(Where two or more symbols separated by commas or semicolons are given for a quantity, these symbols are to be regarded as alternatives for which no preference is expressed. On the other hand, where two symbols are separated by a dotted line, the former is the first preference.)

1. To be Printed in Black Italic.

(Certain important physical constants.)

F	Faraday's constant.
J	Mechanical equivalent of heat.
N	Avogadro's number.
R	{ Gas constant per mol. Rydberg's constant.
c	Velocity of light in vacuo.
e	Electronic charge (charge equal and opposite in sign to that of an electron).
g	Acceleration due to gravity (standard value, if variation from standard is significant).
h	Planck's constant.
k	Boltzmann's constant.
m	Rest mass of an electron.

2. To be Printed in Ordinary Italic, when not Greek.

General Physics and Chemistry.

Length	l
mean free path of molecules	l
height	h
diameter, distance	d
diameter of molecules	σ
radius	r
Mass	m
molecular weight	M
atomic weight	A
atomic number	Z
gram-equivalent weight	Z, J
Time	t
time interval, especially half- or mean-life	τ
frequency	ν
Velocity	$v; c, (u, v, w)$
of ions	u (with subscript)
angular	ω
Acceleration	$f a$
due to gravity (as variable)	g
Force	$F, (X, Y, Z)$
Moment of inertia	I
Pressure	p, P
especially osmotic	Π
Volume	v, V
Density	ρd
Compressibility	κK

Viscosity	η
Fluidity	ϕ
Surface area	A s
Angle of contact	θ
Surface tension	γ σ
Parachor	$[P]$
Surface concentration excess	Γ
Number of mols	n
Concentration, mol fraction	N, x
in other terms	c, C
Solubility	s
Diffusion coefficient	D
Chemical equilibrium constant (products/reactants)	K
solubility product	K_s L
Velocity constant of chemical reaction	k
Number of molecular collisions per second	Z
Partition function	f
Efficiency, of any process	η
Wave function	ψ

Heat and Thermodynamics.

Temperature, on absolute scale, ($^{\circ}\text{K}$)	T
on other scales	θ t
Thermal conductivity	k
Energy (general symbol)	E
Work done by or on a system	w W
Heat entering a system	q
Specific heat	c_p and c_v
molecular heat	C_p and C
Ratio of specific heats	γ
Latent heat, per g.	l
per mol	L
Intrinsic energy	U E
Enthalpy, total heat, or heat content	H
Entropy	S
Free energy (Helmholtz)	A F
Thermodynamic potential, Gibbs function, free	
energy (G. N. Lewis)	G
Vapour pressure constant	i
Chemical potential	μ
Activity	a
coefficient (for molar concentration)	f
Osmotic coefficient	g
Van 't Hoff's factor	i

Electricity.

Quantity of electricity	Q
especially electrostatic charge	e
Potential (difference)	} V
Volta potential	
electrokinetic potential	ζ
especially electromotive force of voltaic cells	E
Potential gradient, in electric field	X
Electronic exit work function	ϕ

Current	I
Resistance	R
specific resistance	ρr
specific conductance	$\kappa \sigma$
Inductance, self	L
mutual	M
Electrostatic capacity	C
Dielectric constant	ϵ
Dipole moment	μ

Electrochemistry.

Degree of electrolytic dissociation	α
Valency of an ion	z
Ionic strength	I
Equivalent conductance	Λ
equivalent ionic conductance, "mobility"	l (with subscript)
Transport number	T (with subscript)
	n (with subscript)
Single electrode potential	e (with subscript),
	E (with subscript)
Electrolytic polarisation, overvoltage	$\eta \pi$

Magnetism.

Magnetic field strength	H
flux	ϕ
permeability	μ
susceptibility—volume	κ
mass	χ
moment	M
induction	B

Optics.

Wave length	λ
Wave number	ν
Intensity of light	I
Refractive index	n (with subscript)
	μ (with subscript)
specific refraction	r (with subscript)
molecular refraction	$[R]$ (with subscript)
Molar extinction coefficient	ϵ
Angle of (optical) rotation	α
specific rotation	$[\alpha]$
Specific magnetic rotation	ω

3. To be Printed in Roman, when not Greek.*(a) Examples of Mathematical Constants and Operators.*

Base of natural logarithms	e
Ratio of circumference to diameter	π
Differential	d
partial	∂
Increment	Δ
very small increment	δ
Sum	Σ
Product	Π
Function	f, ϕ

(b) *Examples of single-letter abbreviations.*

*Ampère (in sub-units)	a.
Volt	v.
Ohm	Ω .
Watt	w.
Farad	F.
Henry	H.
Centigrade	C.
Fahrenheit	F.
Kelvin	K.
Ångstrom unit	Å.
micron	μ .
metre	m.
gram	g.
litre	l.
Röntgen unit	r.
†Normal (concentration)	N.
†Molar (concentration)	M.

The following prefixes to abbreviations for the names of units should be used to indicate the specified multiples or sub-multiples of these units :

M	mega-	$10^6 \times$
k	kilo-	$10^3 \times$
d	deci-	$10^{-1} \times$
c	centi-	$10^{-2} \times$
m	milli-	$10^{-3} \times$
μ	micro-	$10^{-6} \times$

e.g., M Ω . denotes megohm; kw., kilowatt; and μ g., microgram. The use of $\mu\mu$. instead of m μ . to denote 10^{-7} cm., or of γ to denote microgram is deprecated.

4. Subscripts and other Modifying Signs.

(a) *Subscripts to symbols for quantities.*

$I, II \dots$	{ especially with symbols for thermodynamic functions, referring to different systems or different states of a system.
$I, 2 \dots$	
A, B \dots	referring to molecular species A, B, etc.
i	referring to a typical ionic species i .
u	referring to an undissociated molecule.
+,	referring to a positive or negative ion, or to a positive or negative electrode.
p, v, T	indicating constant pressure, volume, and temperature respectively.
q	indicating adiabatic conditions.
w	indicating that no work is performed.
p, c, a	with symbol for an equilibrium constant, indicating that it is expressed in terms of pressure, concentration, or activity.
G, V, L, X	referring to gas, vapour, liquid, and crystalline states, respectively.
f, e, s, t, d	referring to fusion, evaporation (vaporisation of liquid), sublimation, transition, and dissolution or dilution respectively.
c	referring to the critical state or indicating a critical value.
∞	referring to a standard state, or indicating limiting value at infinite dilution.

* *E.g.* "ma." for "milliampère"; but "amp." is preferred for "ampère."

† Separated by a hyphen (and no full stop) from a chemical formula which follows it.

C, D, F *with symbols for optical properties, referring to a particular wavelength.*

Where a subscript has to be added to a symbol which already carries a subscript, the two subscripts may be separated by a comma or the symbol with the first subscript may be enclosed in parentheses with the second subscript outside.

(b) *Other modifying signs.*

- o *as right-hand superscript to symbol (particularly to a symbol for a general thermodynamic function—see p. 1795), referring to a standard state.*
- [] *enclosing formula of chemical substance, indicating its molar concentration.*
- { } *enclosing formula of chemical substance, indicating its molar activity.*

In crystallography it is recommended that :

Millerian indices be enclosed in parentheses, () ;

Laue indices be unenclosed ;

Indices of a plane family be enclosed in braces, { } ;

Indices of a zone axis or line be enclosed in brackets, [] .

Numerals attached to a symbol for a chemical element in various positions have the following meanings :

upper left mass number of atom.

lower left nuclear charge of atom.

lower right number of atoms in molecule.

e.g., ${}^7\text{Li}$; ${}^2\text{H}_2$ (= D_2).

ALPHABETICAL INDEX OF RECOMMENDED SYMBOLS, and single-letter abbreviations.

including all those given in the above lists except prefixes, subscripts and other modifying signs.

The name of any quantity for which a given symbol is a second preference is printed in parentheses.

- A free energy—Helmholtz ; atomic weight ; surface area.
- Å. Ångstrom unit.
- a activity ; (acceleration).
- a. ampère, in sub-units—see footnote, p. 988.
- B magnetic induction.
- C concentration ; electrostatic capacity.
 with subscript : molecular heat capacity.
- c. Centigrade.
- c velocity of light in vacuo.
- c velocity ; concentration.
 with subscript : specific heat.
- D diffusion coefficient.
- d diameter ; distance ; (density).
- d differential.
- ∂ partial differential.
- E energy ; (intrinsic energy) ; potential difference, especially electromotive force of voltaic cells.
 with subscript : single electrode potential.
- e electronic charge—charge equal and opposite in sign to that of an electron.
 quantity of electricity, especially electrostatic charge.
 with subscript : single electrode potential.

- e** base of natural logarithms.
F Faraday's constant.
F force; (free energy—Helmholtz).
F. farad; Fahrenheit.
f acceleration; activity coefficient, for molar concentration; partition function.
f function.
G thermodynamic potential, Gibbs function, free energy—G. N. Lewis.
g acceleration due to gravity, standard value.
g acceleration due to gravity, as a variable; osmotic coefficient.
g. gram.
H enthalpy, total heat, heat content; magnetic field strength.
H. henry.
h Planck's constant.
h height.
I moment of inertia; ionic strength; electric current; intensity of light.
i vapour pressure constant; van 't Hoff's factor.
J mechanical equivalent of heat.
J gram-equivalent weight.
K chemical equilibrium constant; (compressibility).
K, solubility product.
K. Kelvin.
k Boltzmann's constant.
k thermal conductivity; velocity constant of chemical reaction.
L latent heat per mol; self inductance; (solubility product).
l latent heat per g.; length; mean free path of molecules.
with subscript: equivalent ionic conductance, "mobility".
l. litre.
M molecular weight; mutual inductance; magnetic moment.
M. molar concentration.
m rest mass of an electron.
m mass.
m. metre.
N Avogadro's number.
N mol fraction.
N. normal concentration.
n number of mols.
with subscript: (transport number).
with subscript: refractive index.
P pressure.
[P] parachor.
p pressure.
Q quantity of electricity.
q heat entering a system.
R gas constant per mol; Rydberg's constant.
R electrical resistance.
[R] *with subscript*: molecular refraction.
r radius; (specific resistance).
with subscript: specific refraction.
r. Röntgen unit.
S entropy.
s solubility; (surface area).
T temperature, on absolute Kelvin scale.
with subscript: transport number.
t time; (temperature—not on absolute scale).
U intrinsic energy.

u	velocity component. <i>with subscript</i> : velocity of ions.
V	volume; potential, potential difference, including Volta potential.
v	volt.
v	volume; velocity; velocity component.
W	(work done by or on a system).
w	watt.
w	work done by or on a system; velocity component.
X	force component; potential gradient in electric field.
x	mol fraction.
Y	force component.
Z	force component; g.-equivalent weight; number of molecular collisions per second; atomic number.
z	valency of an ion.
α	degree of electrolytic dissociation; angle of optical rotation.
$[\alpha]$	specific optical rotation.
Γ	surface concentration excess.
γ	ratio of specific heats; surface tension.
Δ	increment.
δ	very small increment.
ϵ	dielectric constant; molar extinction coefficient.
ζ	electrokinetic potential.
η	efficiency of any process; viscosity; electrolytic polarisation, overvoltage.
θ	angle of contact; temperature—not on absolute scale.
κ	compressibility; specific conductance; magnetic susceptibility—volume.
Λ	equivalent conductance.
λ	wave length.
μ	chemical potential; dipole moment; magnetic permeability. <i>with subscript</i> : (refractive index).
μ	micron.
ν	frequency; wave number.
Π	pressure, especially osmotic pressure.
Π	product.
π	(electrolytic polarisation, overvoltage).
π	ratio of circumference to diameter.
ρ	density; specific resistance.
Σ	sum.
σ	diameter of molecules; (surface tension); (specific conductance).
τ	time interval, especially half or mean life.
ϕ	fluidity; electronic exit work function; magnetic flux.
Φ	function.
χ	magnetic susceptibility—mass.
ψ	wave function.
Ω	ohm.
ω	angular velocity; specific magnetic rotation.
